Genetics Misconceptions

<u>allele</u>	<u>cont. to phenotype</u>	Autosomal rec.
D	normal (dom)	
d	disease (rec)	

2 parents that are both carriers

Dd x Dd

	D	d
D	DD	Dd
d	Dd	dd

→ $\frac{1}{4}$ chance of
having a child w/
the disease (dd)

Misconceptions

- ① if first kid is dd, next 3 will not have disease

- ② if have 4 kids, only 1 will be dd
- ③ if have 4 kids, at least 1 will be dd
- ④ if one kid dd, next kid is at a lower risk

Genes = destiny?

chance of

being in prison

being on death row

hormone H

genetic element, E,

it occurs in some people

with E (compared to without E)

16x higher

63x higher

10x higher

levels H → correlated w/ increased aggression

Y chromosome

Questions for Chemistry/Biochemistry

① how does a dominant allele dominate?

② why is PKU rec.?

→ how does D allele → tolerance of phen...
d allele → intolerance

Chemistry

functions
of living
things

explain
in terms of

molecules — chemistry

proteins — biochemistry

Subatomic form — molecules — covalent bonds — non-covalent bonds — cell

Brian White, Ph.D. © 2011

Subatomic particles $\xrightarrow{\text{form}}$ atoms $\xrightarrow{\text{bond}}$ molecules $\xrightarrow{\text{}} \text{cell}$

Bio 111 Probability Simulation

Consider an autosomal recessive genetic disease. That is:
the disease is controlled by one gene on an autosome with two alleles:
D - normal (dominant)
d - diseased (recessive)

If the father is Dd, there is a 1/2 chance that he will give a d allele to his offspring.
If the mother is Dd, there is a 1/2 chance that she will give a d allele to her offspring.
If the child gets a d from both mom and from dad, he or she will have the disease.
So, overall, if two carrier (Dd) parents have children, each child has a 1/4 chance of having the disease.

	D	d
D	DD	Dd
d	Dd	dd

We will simulate a family with 4 children.

For each child:

- (1) flip a coin once to choose the allele that the father will contribute.
If it is heads, the allele is D; write the allele in the appropriate box.
If it is tails, the allele is d; write the allele in the appropriate box.
- (2) flip a coin once to choose the allele that the mother will contribute.
If it is heads, the allele is D; write the allele in the appropriate box.
If it is tails, the allele is d; write the allele in the appropriate box.

(you will flip the coin a total of 8 times)

	Genotype		Phenotype
	Allele from Father	Allele from Mother	
First Child	D	d	Normal
Second Child	D	D	normal
Third Child	d	d	disease
Fourth Child	d	D	normal

Genetics 7-2

	Norm	Dis
A	4	0
B	3	1
C	2	2
D	1	3
E	0	4

	class count	predicted	
A	87	96	32%
B	148	126	42%
C	70	63	21%
D	5	14	4.7%
E	9	1	0.3%

Bio 111 Misc. Facts about Genetic Diseases

1) Influence of other factors on severity of selected genetic diseases

(based on figure from "The Metabolic and Molecular Basis of Inherited Disease", Scrivner & al.)

2) Frequency of selected genetic diseases

X-linked

Duchenne Muscular dystrophy	1 in 3000 males
Hemophilia	1 in 10,000 males

Autosomal Recessive

Phenylketonuria	1 in 12,000 (average)
Tay-Sachs Disease	1 in 3,000 (Ashkenazi Jews)
	1 in 320,000 (American non-Jews)
Cystic Fibrosis	1 in 2000 (American Caucasian)
	1 in 17,000 (African-American)

Autosomal Dominant

Marfan Syndrome	1 in 20,000
Achondroplastic Dwarfism	1 in 50,000
