

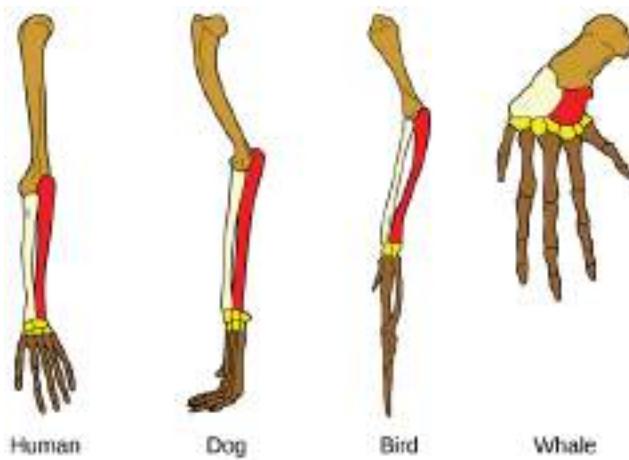

Figure 18.7 The similar construction of these appendages indicates that these organisms share a common ancestor.

Some structures exist in organisms that have no apparent function at all, and appear to be residual parts from a past common ancestor. These unused structures without function are called **vestigial structures**. Examples of vestigial structures include wings on flightless birds, leaves on some cacti, and hind leg bones in whales.

Visit this **interactive site** (http://openstaxcollege.org/l/bone_structures) to guess which bones structures are homologous and which are analogous, and see examples of evolutionary adaptations to illustrate these concepts.

What is the basic difference between things that are homologous and things that are analogous?

- a. Things that are analogous look similar and things that are homologous do not.
- b. Things that are analogous have the same function and things that are homologous have different functions.
- c. Things that are analogous are not a result of evolution, whereas things that are homologous are.
- d. Things that are analogous result from convergence and things that are homologous result from common ancestry

Another evidence of evolution is the convergence of form in organisms that share similar environments. For example, species of unrelated animals, such as the arctic fox and ptarmigan, living in the arctic region have been selected for seasonal white phenotypes during winter to blend with the snow and ice (Figure 18.8ab). These similarities occur not because of common ancestry, but because of similar selection pressures—the benefits of not being seen by predators.

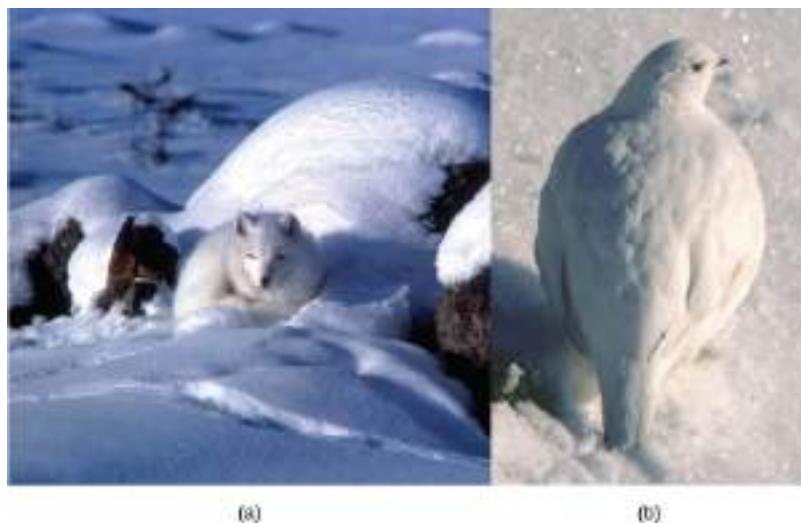

Figure 18.8 The white winter coat of the (a) arctic fox and the (b) ptarmigan's plumage are adaptations to their environments. (credit a: modification of work by Keith Morehouse)

Embryology, the study of the development of the anatomy of an organism to its adult form, also provides evidence of relatedness between now widely divergent groups of organisms. Mutational tweaking in the embryo can have such magnified consequences in the adult that embryo formation tends to be conserved. As a result, structures that are absent in some groups often appear in their embryonic forms and disappear by the time the adult or juvenile form is reached. For example, all vertebrate embryos, including humans, exhibit gill slits and tails at some point in their early development. These disappear in the adults of terrestrial groups but are maintained in adult forms of aquatic groups such as fish and some amphibians. Great ape embryos, including humans, have a tail structure during their development that is lost by the time of birth.

Biogeography

The geographic distribution of organisms on the planet follows patterns that are best explained by evolution in conjunction with the movement of tectonic plates over geological time. Broad groups that evolved before the breakup of the

supercontinent Pangaea (about 200 million years ago) are distributed worldwide. Groups that evolved since the breakup appear uniquely in regions of the planet, such as the unique flora and fauna of northern continents that formed from the supercontinent Laurasia and of the southern continents that formed from the supercontinent Gondwana. The presence of members of the plant family Proteaceae in Australia, southern Africa, and South America, for example, is best explained by their presence prior to the southern supercontinent Gondwana breaking up.

The great diversification of marsupials in Australia and the absence of other mammals reflect Australia's long isolation. Australia has an abundance of endemic species—species found nowhere else—which is typical of islands whose isolation by expanses of water prevents species from migrating. Over time, these species diverge evolutionarily into new species that look very different from their ancestors that may exist on the mainland. The marsupials of Australia, the finches on the Galápagos, and many species on the Hawaiian Islands are all unique to their one point of origin, yet they display distant relationships to ancestral species on mainlands.

Molecular Biology

Like anatomical structures, the structures of the molecules of life reflect descent with modification. Evidence of a common ancestor for all of life is reflected in the universality of DNA as the genetic material and in the near universality of the genetic code and the machinery of DNA replication and expression. Fundamental divisions in life between the three domains are reflected in major structural differences in otherwise conservative structures such as the components of ribosomes and the structures of membranes. In general, the relatedness of groups of organisms is reflected in the similarity of their DNA sequences—exactly the pattern that would be expected from descent and diversification from a common ancestor.

DNA sequences have also shed light on some of the mechanisms of evolution. For example, it is clear that the evolution of new functions for proteins commonly occurs after gene duplication events that allow the free modification of one copy by mutation, selection, or drift (changes in a population's gene pool resulting from chance), while the second copy continues to produce a functional protein.

Direct Observations

Scientists have also observed evolution occurring in both the laboratory and in the wild. A common example of this is the spread of antibiotic resistant genes in a population of bacteria. When bacteria are exposed to antibiotics, alleles that help the organism survive increase in frequency **Figure 18.9**. This is because individuals that cannot resist the antibacterial die off, leaving only individuals with the resistance gene to reproduce.

Figure 18.9

Adaptations for homeostasis

One major reason that organisms adapt is to maintain homeostasis, one of the main characteristics of life. All organisms have likely descended from a single common ancestor, which is why so many organisms share anatomical, morphological, and molecular features. However, each organism has adapted these similar features to suit their environment and adapt to

environmental changes over time. For example, all organisms use DNA polymerase to replicate their genomes. However, whereas organisms with small genomes can get away with just a single polymerase molecule working at one point in the genome at time, organisms with larger genomes replicate many points of the genome simultaneously. Other organisms that live in extremely hot environments, such as deep-sea thermal vents, have specialized polymerase molecules that can withstand the heat that would quickly denature the polymerases in land-based animals. Although the basis for each of these different DNA polymerase molecules is the same, each one has been adapted to function in the organism's environmental niche.

Misconceptions of Evolution

Although the theory of evolution generated some controversy when it was first proposed, it was almost universally accepted by biologists, particularly younger biologists, within 20 years after publication of *On the Origin of Species*. Nevertheless, the theory of evolution is a difficult concept and misconceptions about how it works abound.

This site (<http://openstaxcollege.org/l/misconceptions>) addresses some of the main misconceptions associated with the theory of evolution.

Select one misconception about evolution and explain what you might say to someone to dispel it.

- a. Misconception: Evolution is not a well-founded theory. Correction: Although evolution cannot be observed occurring today, there is strong evidence in the fossil record and in shared DNA sequences to support the theory
- b. Misconception: Humans are not currently evolving. Correction: The environmental pressures humans face are different than the ones they faced several thousands of years ago, but they are still there, and they are still producing (slowly!) evolutionary change.
- c. Misconception: Evolution produces individuals that are perfectly fit to their environment. Correction: Evolution produces random changes in the genetic code that sometimes lead to adaptations
- d. Misconception: Evolution is a random process. Correction: evolution is a force that makes animals adapt to perfectly fit the environment they are living in

Evolution Is Just a Theory

Critics of the theory of evolution dismiss its importance by purposefully confounding the everyday usage of the word “theory” with the way scientists use the word. In science, a “theory” is understood to be a body of thoroughly tested and verified explanations for a set of observations of the natural world. Scientists have a theory of the atom, a theory of gravity, and the theory of relativity, each of which describes understood facts about the world. In the same way, the theory of evolution describes facts about the living world. As such, a theory in science has survived significant efforts to discredit it by scientists. In contrast, a “theory” in common vernacular is a word meaning a guess or suggested explanation; this meaning is more akin to the scientific concept of “hypothesis.” When critics of evolution say evolution is “just a theory,” they are implying that there is little evidence supporting it and that it is still in the process of being rigorously tested. This is a mischaracterization.

Individuals Evolve

Evolution is the change in genetic composition of a population over time, specifically over generations, resulting from differential reproduction of individuals with certain alleles. Individuals do change over their lifetime, obviously, but this is called development and involves changes programmed by the set of genes the individual acquired at birth in coordination with the individual's environment. When thinking about the evolution of a characteristic, it is probably best to think about the change of the average value of the characteristic in the population over time. For example, when natural selection leads to bill-size change in medium-ground finches in the Galápagos, this does not mean that individual bills on the finches are

changing. If one measures the average bill size among all individuals in the population at one time and then measures the average bill size in the population several years later, this average value will be different as a result of evolution. Although some individuals may survive from the first time to the second, they will still have the same bill size; however, there will be many new individuals that contribute to the shift in average bill size.

Evolution Explains the Origin of Life

It is a common misunderstanding that evolution includes an explanation of life's origins. Conversely, some of the theory's critics believe that it cannot explain the origin of life. The theory does not try to explain the origin of life. The theory of evolution explains how populations change over time and how life diversifies the origin of species. It does not shed light on the beginnings of life including the origins of the first cells, which is how life is defined. The mechanisms of the origin of life on Earth are a particularly difficult problem because it occurred a very long time ago, and presumably it just occurred once. Importantly, biologists believe that the presence of life on Earth precludes the possibility that the events that led to life on Earth can be repeated because the intermediate stages would immediately become food for existing living things.

However, once a mechanism of inheritance was in place in the form of a molecule like DNA either within a cell or pre-cell, these entities would be subject to the principle of natural selection. More effective reproducers would increase in frequency at the expense of inefficient reproducers. So while evolution does not explain the origin of life, it may have something to say about some of the processes operating once pre-living entities acquired certain properties.

Organisms Evolve on Purpose

Statements such as “organisms evolve in response to a change in an environment” are quite common, but such statements can lead to two types of misunderstandings. First, the statement must not be understood to mean that individual organisms evolve. The statement is shorthand for “a population evolves in response to a changing environment.” However, a second misunderstanding may arise by interpreting the statement to mean that the evolution is somehow intentional. A changed environment results in some individuals in the population, those with particular phenotypes, benefiting and therefore producing proportionately more offspring than other phenotypes. This results in change in the population if the characteristics are genetically determined.

It is also important to understand that the variation that natural selection works on is already in a population and does not arise in response to an environmental change. For example, applying antibiotics to a population of bacteria will, over time, select a population of bacteria that are resistant to antibiotics. The resistance, which is caused by a gene, did not arise by mutation because of the application of the antibiotic. The gene for resistance was already present in the gene pool of the bacteria, likely at a low frequency. The antibiotic, which kills the bacterial cells without the resistance gene, strongly selects individuals that are resistant, since these would be the only ones that survived and divided. Experiments have demonstrated that mutations for antibiotic resistance do not arise as a result of antibiotic.

In a larger sense, evolution is not goal directed. Species do not become “better” over time; they simply track their changing environment with adaptations that maximize their reproduction in a particular environment at a particular time. Evolution has no goal of making faster, bigger, more complex, or even smarter species, despite the commonness of this kind of language in popular discourse. What characteristics evolve in a species are a function of the variation present and the environment, both of which are constantly changing in a non-directional way. What trait is fit in one environment at one time may well be fatal at some point in the future. This holds equally well for a species of insect as it does the human species.

Activity

Using information from a book or online resource such as Jonathan Weiner's *The Beak of the Finch*, explain how contemporary evidence drawn from multiple scientific disciplines supports the observations of Charles Darwin regarding evolution by natural selection. Then, in small groups or as a whole class discussion or debate, present an argument to dispel misconceptions about evolution and how it works.

Lab Investigation

AP® Biology Investigative Labs: Inquiry-Based, Investigation 8: Biotechnology: Bacterial Transformation. You will explore how genetic engineering techniques can be used to manipulate heritable information by inserting plasmids into bacterial cells.

Think About It

What selection pressures may affect the survival and reproduction of a group of pea seeds scattered by a person along the ground?

18.2 | Formation of New Species

In this section, you will explore the following questions:

- What defines a species, and how can different species be distinguished from each other?
- How does genetic variation lead to speciation?
- What is the role of pre-zygotic and post-zygotic reproductive barriers in speciation?
- What is the difference between allopatric speciation and sympatric speciation?
- How does adaptive radiation explain the diversification?

Connection for AP® Courses

Speciation explains the diversity of organisms that inhabit the Earth. Although all life shares various genetic similarities, only certain organisms combine genetic information by sexual reproduction and produce viable and fertile offspring that, in turn, can successfully reproduce. Scientists call such organisms members of a biological species. As we will study in later, changes in allele frequencies within a population over generations result in microevolution. However, macroevolution leads to the evolution of new species when populations diverge from a common ancestor and, for one reason or another, become reproductively isolated from the original population.

Speciation occurs along two main pathways: geographic separation (**allopatric speciation**) and through mechanisms that occur within a shared habitat (**sympatric speciation**). In both cases, populations become reproductively isolated. When populations become geographically isolated, the free-flow of alleles is prevented. Over time—and because of different selective pressures—the populations diverge and become genetically independent species. **Prezygotic barriers** block reproduction prior to formation of a zygote, whereas **postzygotic barriers** block reproduction after fertilization occurs. Obviously, if two populations are separated by a vast ocean, they will not come in contact with each other to reproduce. However, if speciation has occurred, even when brought back together, they will retain their species identity. There are many examples of this in nature, including Darwin's finches, northern and Mexican spotted owls, and Hawaiian honeycreeper. **Adaptive radiation** occurs when a single ancestral species gives rise to many new species. This may occur, for example, when new habitats become available. It can also be seen historically in the rise of mammals following the extinction of dinosaurs. Other examples of prezygotic isolating mechanisms include mating seasons and unique courtship behaviors. Sometimes mating occurs between two different species, resulting in a **hybrid** such as the mule, which is a cross between a horse and a donkey. However, most hybrids are inviable or sterile.

Sympatric speciation does not require a geographic barrier and explains how many different species can inhabit the same area. One form of sympatric speciation begins with a serious chromosomal error during cell division. As you recall from our exploration of meiosis, sometimes errors occur in the separation of chromosomes or chromatids, resulting in gametes with extra chromosomes (**polyploidy**). This type of speciation is more common in plants than in animals, though some examples in animals exist. For example, two groups of cichlid fish in Africa's Lake Victoria, which have distinct morphologies and diets, may be in the early stage of sympatric speciation without polyploidy, as genetic differences arise between the two groups.

Information presented and the examples highlighted in this section support concepts outlined in Big Idea 1 and Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Big Idea 1	The process of evolution drives the diversity and unity of life.
Enduring Understanding 1.C	Life continues to evolve within a changing environment.
Essential Knowledge	1.C.1 Speciation and extinction have occurred throughout the Earth's history.
Science Practice	5.1 The student can analyze data to identify patterns or relationships.
Learning Objective	1.20 The student is able to analyze data related to questions of speciation and extinction throughout the Earth's history.
Essential Knowledge	1.C.1 Speciation and extinction have occurred throughout the Earth's
Science Practice	4.2 The student can design a plan for collecting data to answer a particular scientific question.
Learning Objective	1.21 The student is able to design a plan for collecting data to investigate the scientific claim that speciation and extinction have occurred throughout the Earth's history.
Essential Knowledge	1.C.2 Speciation may occur when two populations become reproductively isolated from each other.
Science Practice	6.4 The student can make claims and predictions about natural phenomena based on scientific theories and models.
Learning Objective	1.22 The student is able to use data from a real or simulated population(s), based on graphs or models of types of selection, to predict what will happen to the population in the future.
Essential Knowledge	1.C.2 Speciation may occur when two populations become reproductively isolated from each other.
Science Practice	4.1 The student can justify the selection of the kind of data needed to answer a particular scientific question.
Learning Objective	1.23 The student is able to justify the selection of data that address questions related to reproductive isolation and speciation.
Essential Knowledge	1.C.2 Speciation may occur when two populations become reproductively isolated from each other.
Science Practice	6.4 The student can make claims and predictions about natural phenomena based on scientific theories and models.
Learning Objective	1.24 The student is able to describe speciation in an isolated population and connect it to change in gene frequency, change in environment, natural selection, and/or genetic drift.
Big Idea 3	Living systems store, retrieve, transmit and respond to information essential to life processes.

Enduring Understanding 3.C	The processing of genetic information is imperfect and is a source of genetic variation.
Essential Knowledge	3.C.1 Changes in genotype can result in changes in phenotype.
Science Practice	6.4 The student can make claims and predictions about natural phenomena based on scientific theories and models.
Learning Objective	3.24 The student is able to predict how a change in genotype, when expressed as a phenotype, provides a variation that can be subject to natural selection.
Essential Knowledge	3.C.1 Changes in genotype can result in changes in phenotype.
Science Practice	7.2 The student can connect concepts in and across domain(s) to generalize or extrapolate in and/or across enduring understandings and/or big ideas.
Learning Objective	3.26 The student is able to explain the connection between genetic variations in organisms and phenotypic variations in populations.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 2.27][APLO 1.8][APLO 1.23]

Species and the Ability to Reproduce

A species is a group of individual organisms that interbreed and produce fertile, viable offspring. According to this definition, one species is distinguished from another when, in nature, it is not possible for matings between individuals from each species to produce fertile offspring.

Members of the same species share both external and internal characteristics, which develop from their DNA. The closer relationship two organisms share, the more DNA they have in common, just like people and their families. People's DNA is likely to be more like their father or mother's DNA than their cousin or grandparent's DNA. Organisms of the same species have the highest level of DNA alignment and therefore share characteristics and behaviors that lead to successful reproduction.

Species' appearance can be misleading in suggesting an ability or inability to mate. For example, even though domestic dogs (*Canis lupus familiaris*) display phenotypic differences, such as size, build, and coat, most dogs can interbreed and produce viable puppies that can mature and sexually reproduce (Figure 18.10).

Figure 18.10 The (a) poodle and (b) cocker spaniel can reproduce to produce a breed known as (c) the cockapoo. (credit a: modification of work by Sally Eller, Tom Reese; credit b: modification of work by Jeremy McWilliams; credit c: modification of work by Kathleen Conklin)

In other cases, individuals may appear similar although they are not members of the same species. For example, even though bald eagles (*Haliaeetus leucocephalus*) and African fish eagles (*Haliaeetus vocifer*) are both birds and eagles, each belongs to a separate species group (Figure 18.11). If humans were to artificially intervene and fertilize the egg of a bald eagle with the sperm of an African fish eagle and a chick did hatch, that offspring, called a hybrid (a cross between two species), would probably be infertile—unable to successfully reproduce after it reached maturity. Different species may have different genes

that are active in development; therefore, it may not be possible to develop a viable offspring with two different sets of directions. Thus, even though hybridization may take place, the two species still remain separate.

Figure 18.11 The (a) African fish eagle is similar in appearance to the (b) bald eagle, but the two birds are members of different species. (credit a: modification of work by Nigel Wedge; credit b: modification of work by U.S. Fish and Wildlife Service)

Populations of species share a gene pool: a collection of all the variants of genes in the species. Again, the basis to any changes in a group or population of organisms must be genetic for this is the only way to share and pass on traits. When variations occur within a species, they can only be passed to the next generation along two main pathways: asexual reproduction or sexual reproduction. The change will be passed on asexually simply if the reproducing cell possesses the changed trait. For the changed trait to be passed on by sexual reproduction, a gamete, such as a sperm or egg cell, must possess the changed trait. In other words, sexually-reproducing organisms can experience several genetic changes in their body cells, but if these changes do not occur in a sperm or egg cell, the changed trait will never reach the next generation. Only heritable traits can evolve. Therefore, reproduction plays a paramount role for genetic change to take root in a population or species. In short, organisms must be able to reproduce with each other to pass new traits to offspring.

everyday CONNECTION for AP[®] Courses

Until recently, these three species of short-tailed pythons, *Python curtus*, *Python brongersmai* (middle), and *Python breitensteini* were considered one species. However, due to the different locations in which they are found, they have become three distinct species.

Figure 18.12

Until recently, these three species of short-tailed pythons, *Python curtus*, *Python brongersmai* (middle), and *Python breitensteini* were considered one species. However, due to the different locations in which they are found, they have become three distinct species. What is this an example of?

- a. divergent evolution
- b. sympatric speciation
- c. allopatric speciation
- d. variation

Speciation

The biological definition of species, which works for sexually reproducing organisms, is a group of actually or potentially interbreeding individuals. There are exceptions to this rule. Many species are similar enough that hybrid offspring are possible and may often occur in nature, but for the majority of species this rule generally holds. In fact, the presence in nature of hybrids between similar species suggests that they may have descended from a single interbreeding species, and the speciation process may not yet be complete.

Given the extraordinary diversity of life on the planet there must be mechanisms for **speciation**: the formation of two species from one original species. Darwin envisioned this process as a branching event and diagrammed the process in the only illustration found in *On the Origin of Species* (**Figure 18.13a**). Compare this illustration to the diagram of elephant evolution (**Figure 18.13b**), which shows that as one species changes over time, it branches to form more than one new species, repeatedly, as long as the population survives or until the organism becomes extinct.

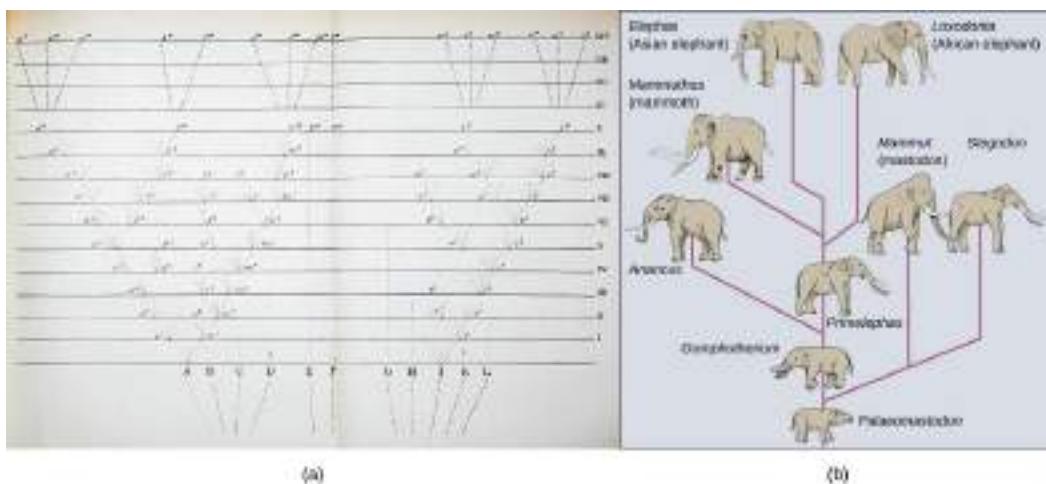

Figure 18.13 The only illustration in Darwin's *On the Origin of Species* is (a) a diagram showing speciation events leading to biological diversity. The diagram shows similarities to phylogenetic charts that are drawn today to illustrate the relationships of species. (b) Modern elephants evolved from the *Palaeomastodon*, a species that lived in Egypt 35–50 million years ago.

For speciation to occur, two new populations must be formed from one original population and they must evolve in such a way that it becomes impossible for individuals from the two new populations to interbreed. Biologists have proposed mechanisms by which this could occur that fall into two broad categories. Allopatric speciation (allo- = "other"; -patric = "homeland") involves geographic separation of populations from a parent species and subsequent evolution. Sympatric speciation (sym- = "same"; -patric = "homeland") involves speciation occurring within a parent species remaining in one location.

Biologists think of speciation events as the splitting of one ancestral species into two descendant species. There is no reason why there might not be more than two species formed at one time except that it is less likely and multiple events can be conceptualized as single splits occurring close in time.

Allopatric Speciation

A geographically continuous population has a gene pool that is relatively homogeneous. Gene flow, the movement of alleles across the range of the species, is relatively free because individuals can move and then mate with individuals in their new location. Thus, the frequency of an allele at one end of a distribution will be similar to the frequency of the allele at the other end. When populations become geographically discontinuous, that free-flow of alleles is prevented. When that separation lasts for a period of time, the two populations are able to evolve along different trajectories. Thus, their allele frequencies at numerous genetic loci gradually become more and more different as new alleles independently arise by mutation in each population. Typically, environmental conditions, such as climate, resources, predators, and competitors for the two populations will differ causing natural selection to favor divergent adaptations in each group.

Isolation of populations leading to allopatric speciation can occur in a variety of ways: a river forming a new branch, erosion forming a new valley, a group of organisms traveling to a new location without the ability to return, or seeds floating over the ocean to an island. The nature of the geographic separation necessary to isolate populations depends entirely on the biology of the organism and its potential for dispersal. If two flying insect populations took up residence in separate nearby valleys, chances are, individuals from each population would fly back and forth continuing gene flow. However, if

two rodent populations became divided by the formation of a new lake, continued gene flow would be unlikely; therefore, speciation would be more likely.

Biologists group allopatric processes into two categories: dispersal and vicariance. **Dispersal** is when a few members of a species move to a new geographical area, and **vicariance** is when a natural situation arises to physically divide organisms.

Scientists have documented numerous cases of allopatric speciation taking place. For example, along the west coast of the United States, two separate sub-species of spotted owls exist. The northern spotted owl has genetic and phenotypic differences from its close relative: the Mexican spotted owl, which lives in the south ([Figure 18.14](#)).

Figure 18.14 The northern spotted owl and the Mexican spotted owl inhabit geographically separate locations with different climates and ecosystems. The owl is an example of allopatric speciation. (credit "northern spotted owl": modification of work by John and Karen Hollingsworth; credit "Mexican spotted owl": modification of work by Bill Radke)

Additionally, scientists have found that the farther the distance between two groups that once were the same species, the more likely it is that speciation will occur. This seems logical because as the distance increases, the various environmental factors would likely have less in common than locations in close proximity. Consider the two owls: in the north, the climate is cooler than in the south; the types of organisms in each ecosystem differ, as do their behaviors and habits; also, the hunting habits and prey choices of the southern owls vary from the northern owls. These variances can lead to evolved differences in the owls, and speciation likely will occur.

Adaptive Radiation

In some cases, a population of one species disperses throughout an area, and each population finds a distinct niche or isolated habitat. Over time, the varied demands of their new lifestyles lead to multiple speciation events originating from a single species. This is called adaptive radiation because many adaptations evolve from a single point of origin; thus, causing the species to radiate into several new ones. Island archipelagos like the Hawaiian Islands provide an ideal context for adaptive radiation events because water surrounds each island which leads to geographical isolation for many organisms. The Hawaiian honeycreeper illustrates one example of adaptive radiation. From a single species, called the founder species, numerous species have evolved, including the six shown in [Figure 18.15](#).

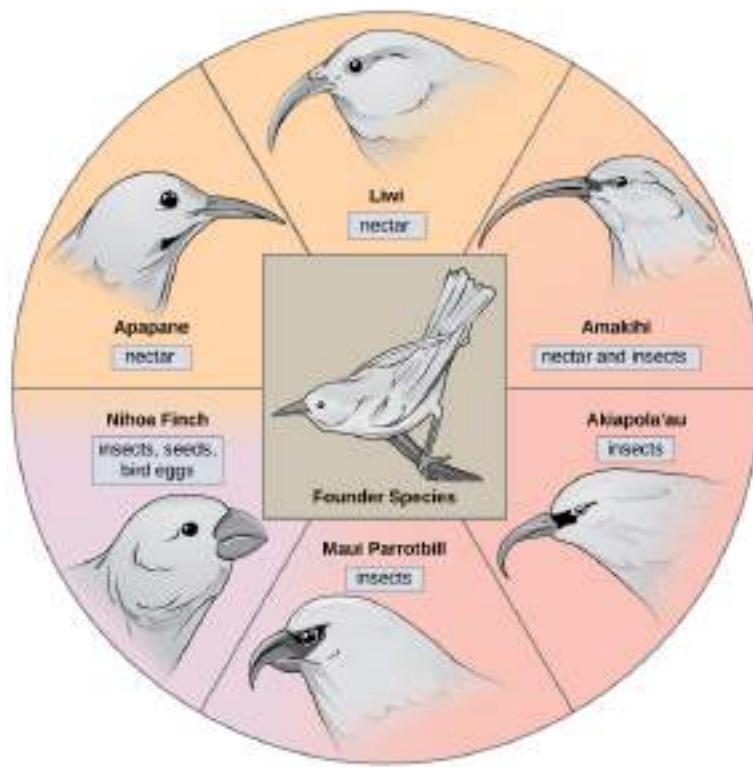

Figure 18.15 The honeycreeper birds illustrate adaptive radiation. From one original species of bird, multiple others evolved, each with its own distinctive characteristics.

Notice the differences in the species' beaks in **Figure 18.15**. Evolution in response to natural selection based on specific food sources in each new habitat led to evolution of a different beak suited to the specific food source. The seed-eating bird has a thicker, stronger beak which is suited to break hard nuts. The nectar-eating birds have long beaks to dip into flowers to reach the nectar. The insect-eating birds have beaks like swords, appropriate for stabbing and impaling insects. Darwin's finches are another example of adaptive radiation in an archipelago.

Click through this **interactive site** (http://openstaxcollege.org/l/bird_evolution) to see how island birds evolved in evolutionary increments from 5 million years ago to today.

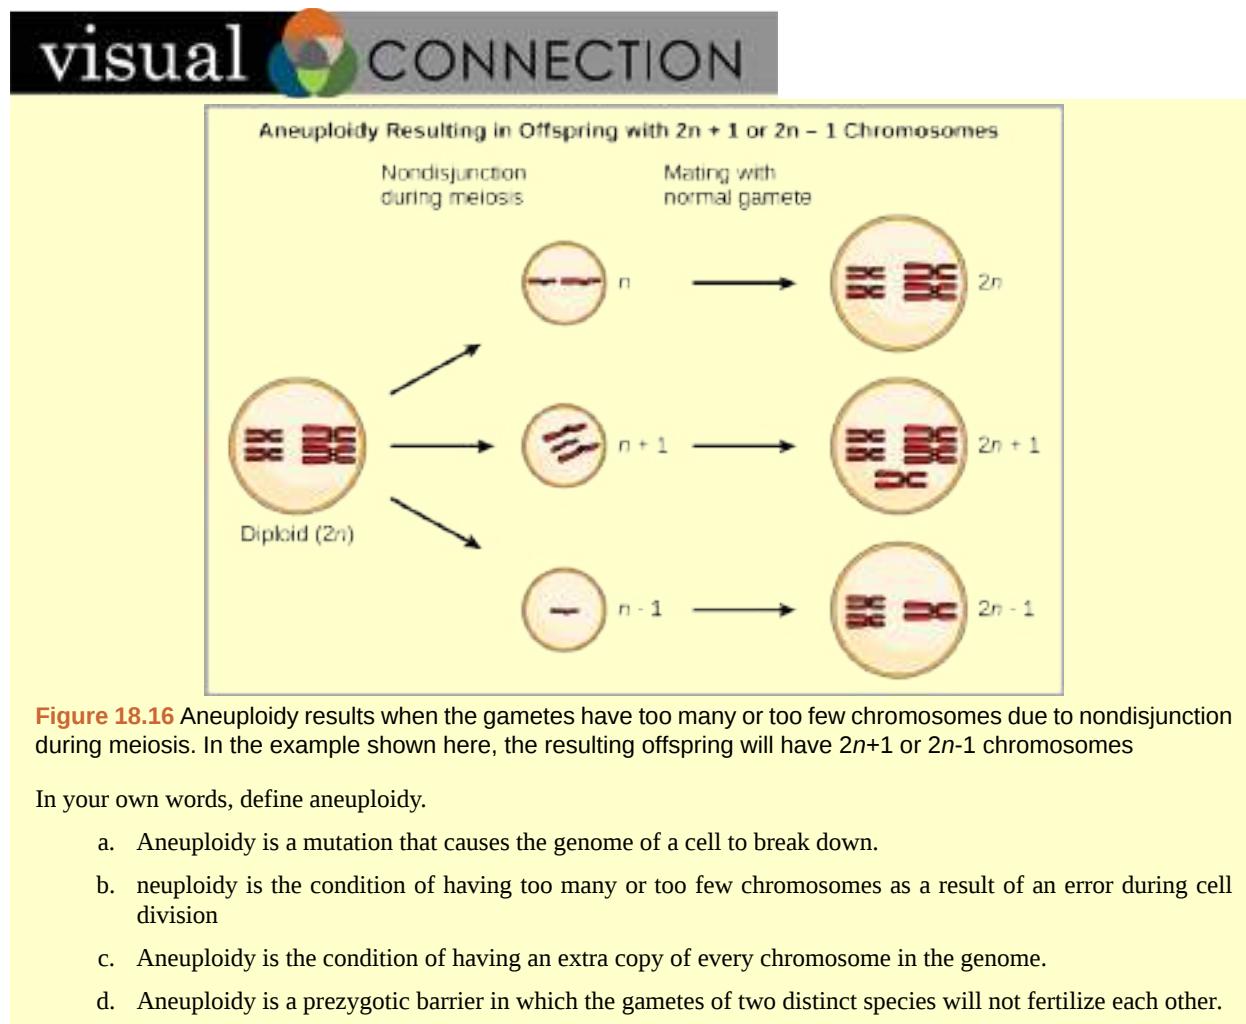

Name three examples of adaptive radiation, and provide a brief statement about each one.

- a. Domestic dogs – There are over 300 distinct dog breeds. Cows – There are over 800 cow breeds recognized worldwide. Domestic cats – Cats have changed drastically in just a few thousand years.
- b. Whales and fish – Although it has been roughly 400 million years since fish and mammals diverged, whales and fish are morphologically similar. Birds and butterflies – Although the common ancestor between vertebrates and insects lived even longer ago than the common ancestor between whales and fish, birds and butterflies both developed flight. Rabbits and kangaroos – Although it has been over 150 million years since their divergence, rabbits and kangaroos both developed powerful jumping legs.
- c. Hawaiian silverswords-There are about 30 species evolved from one parent species. Madagascar lemurs-Their common ancestor likely arrived to Madagascar over 60 million years ago. Hawaiian fruit fly-There are 500 species of fruit fly from one parent species.
- d. Beetles – There are about 350,000 species of beetles that we know of. Birds – There are almost 10,000 species of birds in existence. Frogs – There are almost 5,000 species of frogs worldwide.

Sympatric Speciation

Can divergence occur if no physical barriers are in place to separate individuals who continue to live and reproduce in the same habitat? The answer is yes. The process of speciation within the same space is called sympatric speciation; the prefix “sym” means same, so “sympatric” means “same homeland” in contrast to “allopatric” meaning “other homeland.” A number of mechanisms for sympatric speciation have been proposed and studied.

One form of sympatric speciation can begin with a serious chromosomal error during cell division. In a normal cell division event chromosomes replicate, pair up, and then separate so that each new cell has the same number of chromosomes. However, sometimes the pairs separate and the end cell product has too many or too few individual chromosomes in a condition called **aneuploidy** (Figure 18.16).

Polyplody is a condition in which a cell or organism has an extra set, or sets, of chromosomes. Scientists have identified two main types of polyplody that can lead to reproductive isolation of an individual in the polyplody state. Reproductive isolation is the inability to interbreed. In some cases, a polyploid individual will have two or more complete sets of chromosomes from its own species in a condition called **autopolyploidy** (Figure 18.17). The prefix “auto-” means “self,” so the term means multiple chromosomes from one’s own species. Polyploidy results from an error in meiosis in which all of the chromosomes move into one cell instead of separating.

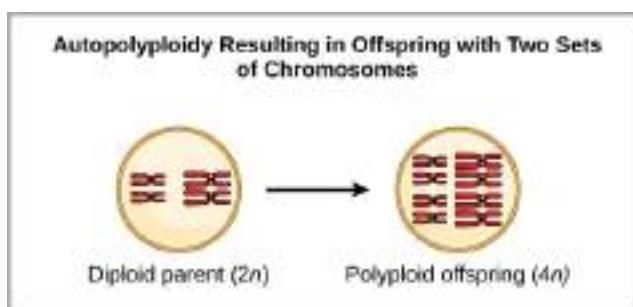

Figure 18.17 Autopolyploidy results when mitosis is not followed by cytokinesis.

For example, if a plant species with $2n = 6$ produces autopolyploid gametes that are also diploid ($2n = 6$, when they should be $n = 3$), the gametes now have twice as many chromosomes as they should have. These new gametes will be incompatible with the normal gametes produced by this plant species. However, they could either self-pollinate or reproduce with other autopolyploid plants with gametes having the same diploid number. In this way, sympatric speciation can occur quickly by

forming offspring with $4n$ called a tetraploid. These individuals would immediately be able to reproduce only with those of this new kind and not those of the ancestral species.

The other form of polyploidy occurs when individuals of two different species reproduce to form a viable offspring called an **allopolyploid**. The prefix “allo-” means “other” (recall from allopatric); therefore, an allopolyploid occurs when gametes from two different species combine. **Figure 18.18** illustrates one possible way an allopolyploid can form. Notice how it takes two generations, or two reproductive acts, before the viable fertile hybrid results.

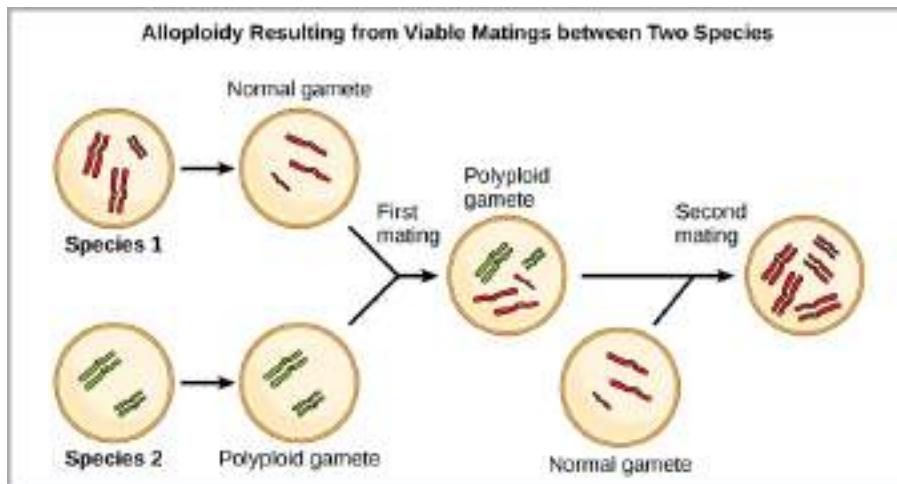

Figure 18.18 Allopolyploidy results when two species mate to produce viable offspring. In the example shown, a normal gamete from one species fuses with a polyploid gamete from another. Two matings are necessary to produce viable offspring.

The cultivated forms of wheat, cotton, and tobacco plants are all allopolyploids. Although polyploidy occurs occasionally in animals, it takes place most commonly in plants. (Animals with any of the types of chromosomal aberrations described here are unlikely to survive and produce normal offspring.) Scientists have discovered more than half of all plant species studied relate back to a species evolved through polyploidy. With such a high rate of polyploidy in plants, some scientists hypothesize that this mechanism takes place more as an adaptation than as an error.

science practices CONNECTION for AP® Courses

Activity

Create a visual representation such as a diagram with annotation to explain how island chains provide ideal conditions for allopatric speciation and adaptive radiation to occur. Then design a plan for collecting data to support the claim that speciation has occurred.

Think About It

- Two species of fish had recently undergone sympatric speciation. The males of each species had a different coloring through which the females could identify and choose a partner from her own species. After some time, pollution made the lake so cloudy that it was hard for females to distinguish colors. What might take place in this situation?
- In a lake where most fish of a single species exhibit colorful stripes, a few individual animals have muted colors. The local fisherman receives a large order to catch the most colorful fish for a local aquarium store. The fisherman casts wide nets across the lake to catch a large number of the fish. He then keeps the colorful fish for the aquarium and throws back the dull colored fish. How will this single event change the make-up of the fish population?

Reproductive Isolation

Given enough time, the genetic and phenotypic divergence between populations will affect characters that influence reproduction: if individuals of the two populations were to be brought together, mating would be less likely, but if mating

occurred, offspring would be non-viable or infertile. Many types of diverging characters may affect the **reproductive isolation** (the inability to interbreed) of the two populations.

Reproductive isolation can take place in a variety of ways. Scientists organize them into two groups: prezygotic barriers and postzygotic barriers. Recall that a zygote is a fertilized egg: the first cell of the development of an organism that reproduces sexually. Therefore, a prezygotic barrier is a mechanism that blocks reproduction from taking place; this includes barriers that prevent fertilization when organisms attempt reproduction. A postzygotic barrier occurs after zygote formation; this includes organisms that don't survive the embryonic stage and those that are born sterile.

Some types of prezygotic barriers prevent reproduction entirely. Many organisms only reproduce at certain times of the year, often just annually. Differences in breeding schedules, called **temporal isolation**, can act as a form of reproductive isolation. For example, two species of frogs inhabit the same area, but one reproduces from January to March, whereas the other reproduces from March to May (Figure 18.19).

Figure 18.19 These two related frog species exhibit temporal reproductive isolation. (a) *Rana aurora* breeds earlier in the year than (b) *Rana boylii*. (credit a: modification of work by Mark R. Jennings, USFWS; credit b: modification of work by Alessandro Catenazzi)

In some cases, populations of a species move or are moved to a new habitat and take up residence in a place that no longer overlaps with the other populations of the same species. This situation is called **habitat isolation**. Reproduction with the parent species ceases, and a new group exists that is now reproductively and genetically independent. For example, a cricket population that was divided after a flood could no longer interact with each other. Over time, the forces of natural selection, mutation, and genetic drift will likely result in the divergence of the two groups (Figure 18.20).

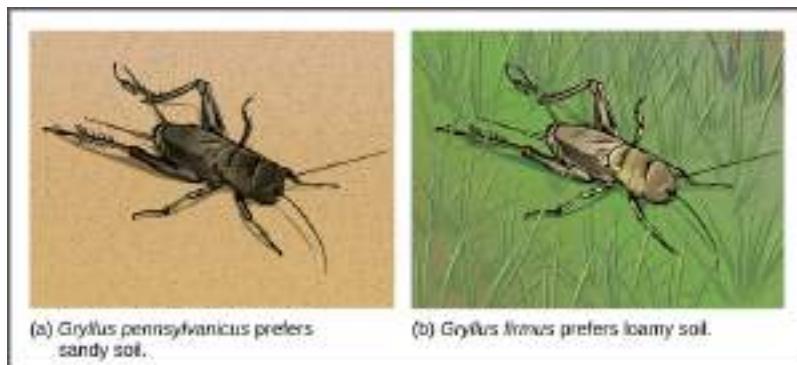

Figure 18.20 Speciation can occur when two populations occupy different habitats. The habitats need not be far apart. The cricket (a) *Gryllus pennsylvanicus* prefers sandy soil, and the cricket (b) *Gryllus firmus* prefers loamy soil. The two species can live in close proximity, but because of their different soil preferences, they became genetically isolated.

Behavioral isolation occurs when the presence or absence of a specific behavior prevents reproduction from taking place. For example, male fireflies use specific light patterns to attract females. Various species of fireflies display their lights differently. If a male of one species tried to attract the female of another, she would not recognize the light pattern and would not mate with the male.

Other prezygotic barriers work when differences in their gamete cells (eggs and sperm) prevent fertilization from taking place; this is called a **gametic barrier**. Similarly, in some cases closely related organisms try to mate, but their reproductive structures simply do not fit together. For example, damselfly males and females of different species have differently shaped reproductive organs. If one species tries to mate with another, their body parts simply do not fit together. (Figure 18.21).

Figure 18.21 The shape of the male reproductive organ varies among male damselfly species, and is only compatible with the female of the same species. Reproductive organ incompatibility keeps each species reproductively isolated.

In plants, certain structures aimed to attract one type of pollinator simultaneously prevent a different pollinator from accessing the pollen. The tunnel through which an animal must access nectar can vary widely in length and diameter, which prevents the plant from being cross-pollinated with a different species (**Figure 18.22**).

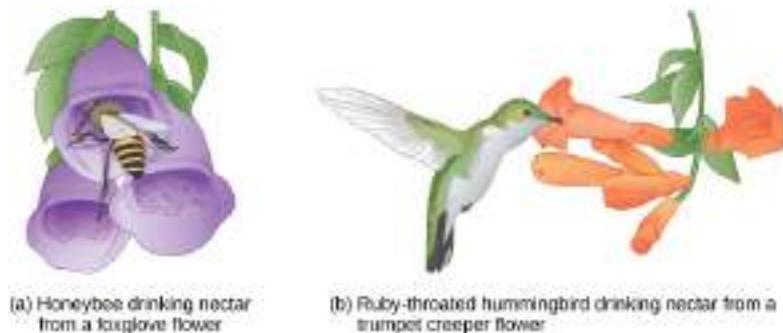

Figure 18.22 Some flowers have evolved to attract certain pollinators. The (a) wide foxglove flower is adapted for pollination by bees, while the (b) long, tube-shaped trumpet creeper flower is adapted for pollination by hummingbirds.

When fertilization takes place and a zygote forms, postzygotic barriers can prevent reproduction. Hybrid individuals in many cases cannot form normally in the womb and simply do not survive past the embryonic stages. This is called **hybrid inviability** because the hybrid organisms simply are not viable. In another postzygotic situation, reproduction leads to the birth and growth of a hybrid that is sterile and unable to reproduce offspring of their own; this is called **hybrid sterility**.

Habitat Influence on Speciation

Sympatric speciation may also take place in ways other than polyploidy. For example, consider a species of fish that lives in a lake. As the population grows, competition for food also grows. Under pressure to find food, suppose that a group of these fish had the genetic flexibility to discover and feed off another resource that was unused by the other fish. What if this new food source was found at a different depth of the lake? Over time, those feeding on the second food source would interact more with each other than the other fish; therefore, they would breed together as well. Offspring of these fish would likely behave as their parents: feeding and living in the same area and keeping separate from the original population. If this group of fish continued to remain separate from the first population, eventually sympatric speciation might occur as more genetic differences accumulated between them.

This scenario does play out in nature, as do others that lead to reproductive isolation. One such place is Lake Victoria in Africa, famous for its sympatric speciation of cichlid fish. Researchers have found hundreds of sympatric speciation events in these fish, which have not only happened in great number, but also over a short period of time. **Figure 18.23** shows this type of speciation among a cichlid fish population in Nicaragua. In this locale, two types of cichlids live in the same geographic location but have come to have different morphologies that allow them to eat various food sources.

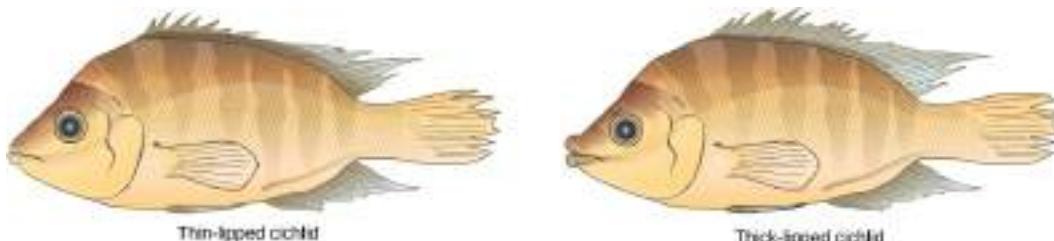

Figure 18.23 Cichlid fish from Lake Apoyeque, Nicaragua, show evidence of sympatric speciation. Lake Apoyeque, a crater lake, is 1800 years old, but genetic evidence indicates that the lake was populated only 100 years ago by a single population of cichlid fish. Nevertheless, two populations with distinct morphologies and diets now exist in the lake, and scientists believe these populations may be in an early stage of speciation.

18.3 | Reconnection and Rates of Speciation

In this section, you will explore the following questions:

- What are the pathways of species evolution in hybrid zones?
- What are the two major theories on rates of speciation?

Connection for AP® Courses

Speciation can both occur gradually over time in small steps or in bursts of change known as punctuated equilibrium. With punctuated equilibrium, a species may remain unchanged for long periods of time. The primary influencing factor on changes in speciation rate is environmental change.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Big Idea 1	The process of evolution drives the diversity and unity of life.
Enduring Understanding 1.C	Life continues to evolve within a changing environment.
Essential Knowledge	1.C.1 Speciation and extinction have occurred throughout Earth's history.
Science Practice	5.1 The student can analyze data to identify patterns or relationships.
Learning Objective	1.20 The student is able to analyze data related to questions of speciation and extinction throughout the Earth's history.

Speciation occurs over a span of evolutionary time, so when a new species arises, there is a transition period during which the closely related species continue to interact.

Reconnection

After speciation, two species may continue interacting indefinitely or even recombine. Individual organisms will mate with any nearby individual who they are capable of breeding with. An area where two closely related species continue to interact and reproduce, forming hybrids, is called a **hybrid zone**. Over time, the hybrid zone may change depending on the fitness of the hybrids and the reproductive barriers ([Figure 18.24](#)). If the hybrids are less fit than the parents, reinforcement of speciation occurs, and the species continue to diverge until they can no longer mate and produce viable offspring. If reproductive barriers weaken, fusion occurs and the two species become one. Barriers remain the same if hybrids are fit and reproductive: stability may occur and hybridization continues.

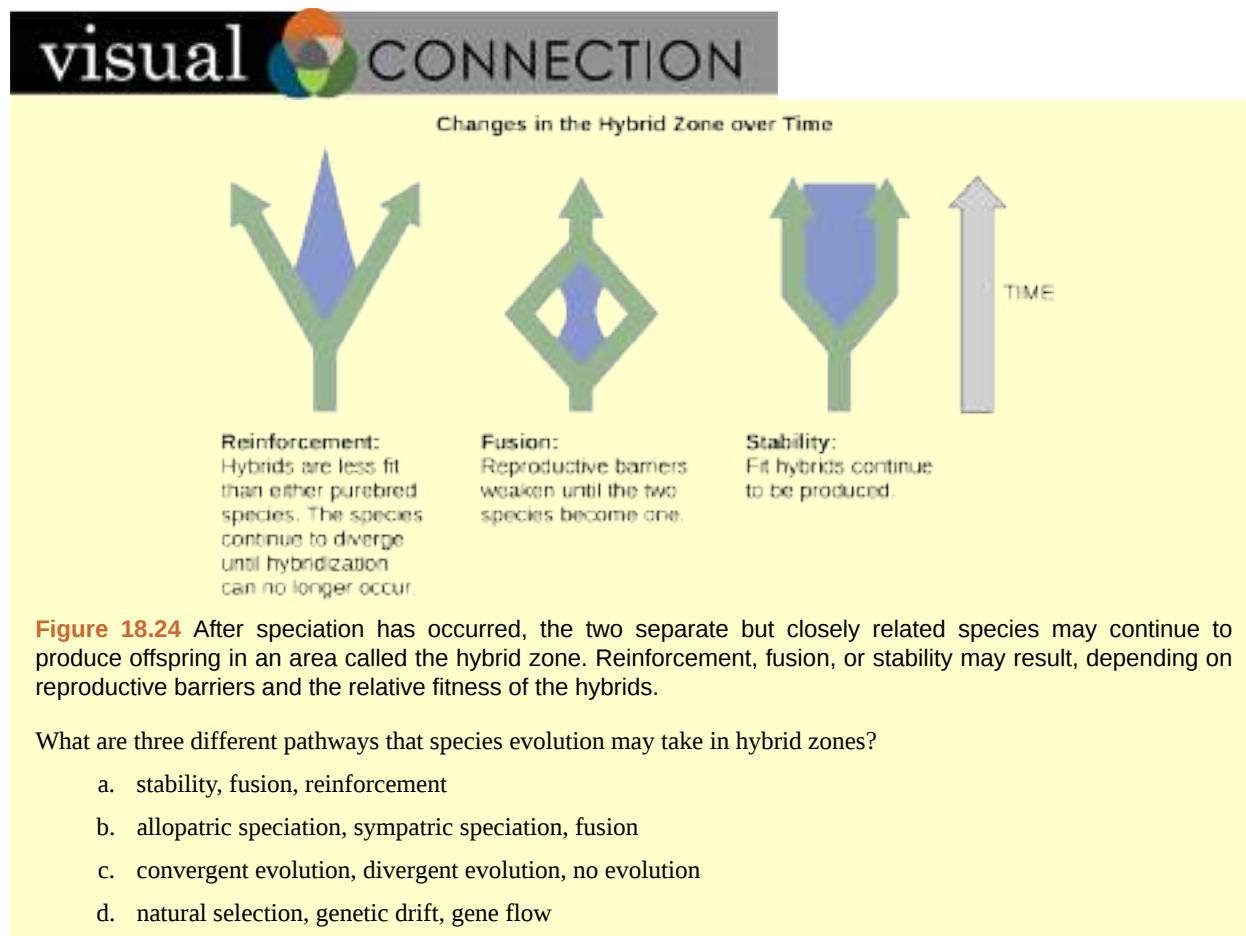

Figure 18.24 After speciation has occurred, the two separate but closely related species may continue to produce offspring in an area called the hybrid zone. Reinforcement, fusion, or stability may result, depending on reproductive barriers and the relative fitness of the hybrids.

What are three different pathways that species evolution may take in hybrid zones?

- stability, fusion, reinforcement
- allopatric speciation, sympatric speciation, fusion
- convergent evolution, divergent evolution, no evolution
- natural selection, genetic drift, gene flow

Hybrids can be either less fit than the parents, more fit, or about the same. Usually hybrids tend to be less fit; therefore, such reproduction diminishes over time, nudging the two species to diverge further in a process called **reinforcement**. This term is used because the low success of the hybrids reinforces the original speciation. If the hybrids are as fit or more fit than the parents, the two species may fuse back into one species (**Figure 18.25**). Scientists have also observed that sometimes two species will remain separate but also continue to interact to produce some hybrid individuals; this is classified as stability because no real net change is taking place.

Varying Rates of Speciation

Scientists around the world study speciation, documenting observations both of living organisms and those found in the fossil record. As their ideas take shape and as research reveals new details about how life evolves, they develop models to help explain rates of speciation. In terms of how quickly speciation occurs, two patterns are currently observed: gradual speciation model and punctuated equilibrium model.

In the **gradual speciation model**, species diverge gradually over time in small steps. In the **punctuated equilibrium** model, a new species undergoes changes quickly from the parent species, and then remains largely unchanged for long periods of time afterward (**Figure 18.25**). This early change model is called punctuated equilibrium, because it begins with a punctuated or periodic change and then remains in balance afterward. While punctuated equilibrium suggests a faster tempo, it does not necessarily exclude gradualism.

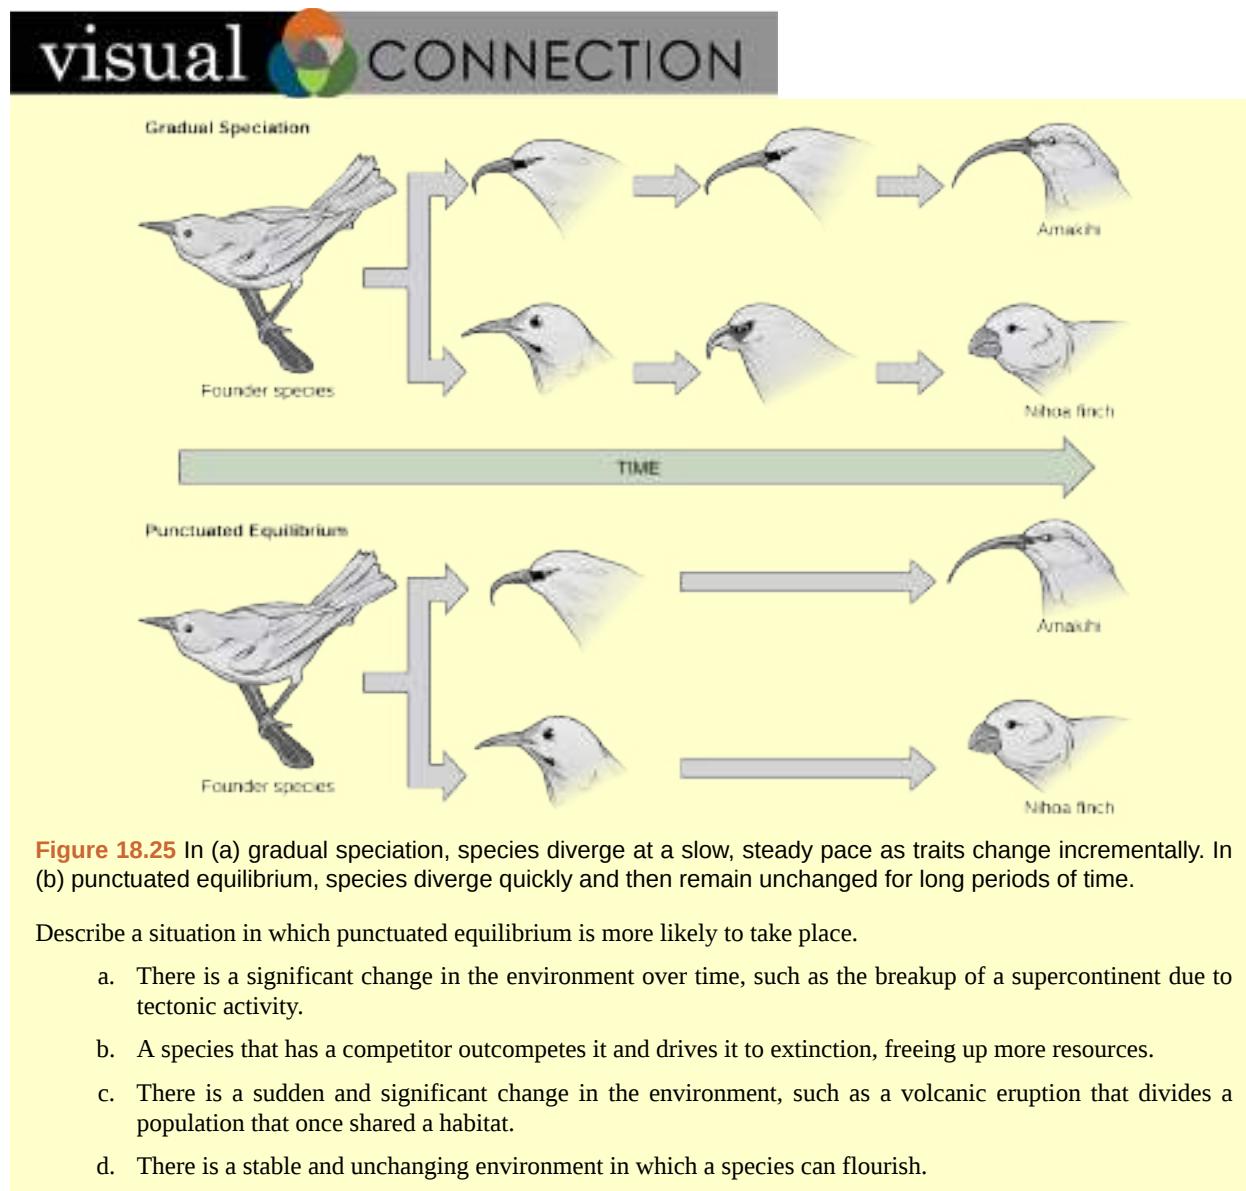

Figure 18.25 In (a) gradual speciation, species diverge at a slow, steady pace as traits change incrementally. In (b) punctuated equilibrium, species diverge quickly and then remain unchanged for long periods of time.

Describe a situation in which punctuated equilibrium is more likely to take place.

- There is a significant change in the environment over time, such as the breakup of a supercontinent due to tectonic activity.
- A species that has a competitor outcompetes it and drives it to extinction, freeing up more resources.
- There is a sudden and significant change in the environment, such as a volcanic eruption that divides a population that once shared a habitat.
- There is a stable and unchanging environment in which a species can flourish.

The primary influencing factor on changes in speciation rate is environmental conditions. Under some conditions, selection occurs quickly or radically. Consider a species of snails that had been living with the same basic form for many thousands of years. Layers of their fossils would appear similar for a long time. When a change in the environment takes place—such as a drop in the water level—a small number of organisms are separated from the rest in a brief period of time, essentially forming one large and one tiny population. The tiny population faces new environmental conditions. Because its gene pool quickly became so small, any variation that surfaces and that aids in surviving the new conditions becomes the predominant form.

Visit **this website** (<http://openstaxcollege.org/l/snails>) to continue the speciation story of the snails.

KEY TERMS

- acquired characteristics** modifications caused by an individual's environment that can be inherited by its offspring
- adaptation** heritable trait or behavior in an organism that aids in its survival and reproduction in its present environment
- adaptive radiation** speciation when one species radiates out to form several other species
- allopatric speciation** speciation that occurs via geographic separation
- allopolyploid** polyploidy formed between two related, but separate species
- aneuploidy** condition of a cell having an extra chromosome or missing a chromosome for its species
- autopolyploid** polyploidy formed within a single species
- behavioral isolation** type of reproductive isolation that occurs when a specific behavior or lack of one prevents reproduction from taking place
- convergent evolution** process by which groups of organisms independently evolve to similar forms
- dispersal** allopatric speciation that occurs when a few members of a species move to a new geographical area
- divergent evolution** process by which groups of organisms evolve in diverse directions from a common point
- gametic barrier** prezygotic barrier occurring when closely related individuals of different species mate, but differences in their gamete cells (eggs and sperm) prevent fertilization from taking place
- gradual speciation model** model that shows how species diverge gradually over time in small steps
- habitat isolation** reproductive isolation resulting when populations of a species move or are moved to a new habitat, taking up residence in a place that no longer overlaps with the other populations of the same species
- homologous structures** parallel structures in diverse organisms that have a common ancestor
- hybrid** offspring of two closely related individuals, not of the same species
- hybrid zone** area where two closely related species continue to interact and reproduce, forming hybrids
- natural selection** reproduction of individuals with favorable genetic traits that survive environmental change because of those traits, leading to evolutionary change
- polyploidy** gametes with extra chromosomes
- postzygotic barrier** reproductive isolation mechanism that occurs after zygote formation
- prezygotic barrier** reproductive isolation mechanism that occurs before zygote formation
- punctuated equilibrium** model for rapid speciation that can occur when an event causes a small portion of a population to be cut off from the rest of the population
- reinforcement** continued speciation divergence between two related species due to low fitness of hybrids between them
- reproductive isolation** situation that occurs when a species is reproductively independent from other species; this may be brought about by behavior, location, or reproductive barriers
- speciation** formation of a new species
- species** group of populations that interbreed and produce fertile offspring
- sympatric speciation** speciation that occurs in the same geographic space
- temporal isolation** differences in breeding schedules that can act as a form of prezygotic barrier leading to reproductive

isolation

theory of evolution explains how populations change over time and how life diversifies the origin of species

variation genetic differences among individuals in a population

vestigial structure physical structure present in an organism but that has no apparent function and appears to be from a functional structure in a distant ancestor

vicariance allopatric speciation that occurs when something in the environment separates organisms of the same species into separate groups

CHAPTER SUMMARY

18.1 Understanding Evolution

Evolution is the process of adaptation through mutation which allows more desirable characteristics to be passed to the next generation. Over time, organisms evolve more characteristics that are beneficial to their survival. For living organisms to adapt and change to environmental pressures, genetic variation must be present. With genetic variation, individuals have differences in form and function that allow some to survive certain conditions better than others. These organisms pass their favorable traits to their offspring. Eventually, environments change, and what was once a desirable, advantageous trait may become an undesirable trait and organisms may further evolve. Evolution may be convergent with similar traits evolving in multiple species or divergent with diverse traits evolving in multiple species that came from a common ancestor. Evidence of evolution can be observed by means of DNA code and the fossil record, and also by the existence of homologous and vestigial structures.

18.2 Formation of New Species

Speciation occurs along two main pathways: geographic separation (allopatric speciation) and through mechanisms that occur within a shared habitat (sympatric speciation). Both pathways isolate a population reproductively in some form. Mechanisms of reproductive isolation act as barriers between closely related species, enabling them to diverge and exist as genetically independent species. Prezygotic barriers block reproduction prior to formation of a zygote, whereas postzygotic barriers block reproduction after fertilization occurs. For a new species to develop, something must cause a breach in the reproductive barriers. Sympatric speciation can occur through errors in meiosis that form gametes with extra chromosomes (polyploidy). Autopolyploidy occurs within a single species, whereas allopolyploidy occurs between closely related species.

18.3 Reconnection and Rates of Speciation

Speciation is not a precise division: overlap between closely related species can occur in areas called hybrid zones. Organisms reproduce with other similar organisms. The fitness of these hybrid offspring can affect the evolutionary path of the two species. Scientists propose two models for the rate of speciation: one model illustrates how a species can change slowly over time; the other model demonstrates how change can occur quickly from a parent generation to a new species. Both models continue to follow the patterns of natural selection.

REVIEW QUESTIONS

1. Which scientific concept did Charles Darwin and Alfred Wallace independently discover?
 - a. mutation
 - b. natural selection
 - c. overbreeding
 - d. sexual reproduction
2. Which of these statements about a natural principle that points to the inevitability of natural selection is false?
 - a. Most characteristics of organisms are inherited.
 - b. Offspring vary among each other in regard to their characteristics.
 - c. Some generations of offspring do not need to compete for resources.
 - d. Certain traits will be better represented in the next generation.
3. Which is the best definition of adaptation?

- a. a trait or behavior that aids an organism's survival and reproduction
- b. a heritable trait or behavior that aids an organism's survival and reproduction
- c. a trait or behavior that aids a population's survival and reproduction
- d. a heritable trait or behavior that aids a population's survival and reproduction
- 4.** Which is an example of an adaptation?
- a. The better nutrition of a human helps her grow taller.
- b. The webbed feet of a duck help it swim.
- c. The urban location of a raccoon helps it find food.
- d. The large leaves of a desert plant require more water.
- 5.** Which of the processes described is divergent evolution?
- a. Groups of organisms evolve in different directions from a common point.
- b. A new species develops rapidly when an event cuts off a portion of a population.
- c. Groups of organisms independently evolve to similar forms.
- d. A species evolves when a few members move to a new geographical area.
- 6.** Which situation is most likely an example of convergent evolution?
- a. Some fish that live in total darkness have eyes.
- b. Hawks and other birds have feathers.
- c. Worms and snakes both move without legs.
- d. Flowers that look very different have the same reproductive organs.
- 7.** What are homologous structures?
- a. physical structures that have no apparent function
- b. parallel structures in diverse organisms
- c. physical structures that are used only occasionally
- d. similar structures in diverse organisms
- 8.** Which of the following are two examples of vestigial structures?
- a. gills in fish and parts of the throat in humans
- b. butterfly wings and dragonfly wings
- c. hind leg bones in whales and leaves on some cacti
- d. shark fins and dolphin fins
- 9.** Which statement best describes the relationship between the theory of evolution and the origin of life?
- a. The theory includes an explanation of life's origins.
- b. The theory cannot explain the origin of life.
- c. The theory does not try to explain the origin of life.
- d. The theory does not contribute understanding to pre-life processes.
- 10.** Which best describes what happens when an antibiotic is applied to a population of bacteria?
- a. The bacteria develops resistance to the antibiotic in direct response to its application.
- b. The bacteria's genetic material mutates in response to the antibiotic, resulting in resistance.
- c. A gene for resistance, already present in the population, decreases in frequency.
- d. A gene for resistance, already present in the population, increases in frequency.
- 11.** Which is the best definition of species?
- a. A group of individual organisms with significant genetic similarities
- b. a group of individual organisms with significant genetic similarities that share external and internal characteristics
- c. a group of individual organisms that interbreed
- d. a group of individual organisms that interbreed and produce viable, fertile offspring
- 12.** What do scientists focus on to distinguish between species?
- a. ecological niches
- b. morphological differences
- c. reproductive barriers
- d. genetic changes
- 13.** Which are two primary sources of genetic variation?
- a. mutations and sexual reproduction
- b. isolation and sexual reproduction
- c. sexual reproduction and asexual reproduction
- d. migration and sexual reproduction
- 14.** Which statement best describes the relationship between genetic variation and speciation?

- a. Without genetic variation, speciation would occur more slowly.
- b. Without genetic variation, speciation would not be possible.
- c. Genetic variation influences sympatric speciation, but not allopatric speciation.
- d. There is no relationship between genetic variation and any form of speciation.
- 15.** Which statement about postzygotic barriers is false?
- They occur after fertilization.
 - They include hybrids that are sterile.
 - They include hybrid organisms that don't survive the embryonic stage.
 - They include reproductive organ incompatibility.
- 16.** Which situation is an example of a prezygotic barrier?
- Two species of fish produce sterile offspring.
 - Two species of flowers attract different pollinators.
 - Two species of insects mate, but the zygote does not survive.
 - Two species of lizards mate, but the offspring dies before reproducing.
- 17.** Which situation would most likely lead to allopatric speciation?
- A flood causes the formation of a new lake
 - A storm causes several large trees to fall down.
 - A mutation causes a new trait to develop.
 - An injury causes an organism to seek out a new food source.
- 18.** What is the main difference between an autopolyploid individual and a allopolypliod individual?
- number of extra chromosomes
 - functionality of extra chromosomes
 - source of extra chromosomes
 - number of mutations in the extra chromosomes
- 19.** What is unique about speciation due to adaptive radiation?
- a. It leads to multiple species forming from one parent species.
- b. It only occurs on or around island archipelagos.
- c. It requires a population to disperse from its parent species.
- d. It is a special kind of sympatric speciation.
- 20.** Which is least likely to be a factor that increases the probability of speciation by adaptive radiation?
- There are vacant ecological niches nearby.
 - Genetic drift in a population increases.
 - There are isolated regions with suitable habitats.
 - There are few competitor species.
- 21.** In a hybrid zone, in addition to interacting, what else do two closely related species do?
- compete
 - reproduce
 - transition
 - fuse
- 22.** Which situation means reinforcement is more likely to occur in the hybrid zone?
- The hybrid offspring are more fit than the parent species.
 - Reproductive barriers weaken.
 - The hybrid offspring are about as fit as the parent species.
 - Reproductive barriers strengthen.
- 23.** Which of the following statements is false?
- Graudal speciation and punctuated equilibrium both result in the divergence of species.
 - Punctuated equilibrium is most likely to occur in a large population in a stable environment.
 - In the punctuated equilibrium model, gradualism is not excluded.
 - In the gradual speciation model, traits change incrementally.
- 24.** Which component of speciation would be least likely to be a part of punctuated equilibrium?
- a division in populations
 - a change in environmental conditions
 - ongoing gene flow
 - a number of mutations occurring at once

CRITICAL THINKING QUESTIONS

- 25.** What conclusions can you draw about the relationship between the way in which the present-day theory of evolution developed and the credibility of the theory?

Explain your thinking.

- a. When the theory of evolution was first proposed, it met with a lot of criticism and disbelief, but it is widely supported today. Theories that have withstood a larger amount of criticism are more credible than those that are accepted easily
- b. The theory of evolution has its foundation in both biological and geological observations, making it a more credible theory because it can explain more about the world
- c. The theory of evolution relies on the heritability of traits, but the mechanism of this inheritance was not understood when the theory was developed. This reduces the credibility of the theory because the people who created it did not understand how it worked
- d. It is meaningful that two naturalists working independently from each other offered the same explanation for the same set of phenomena. When two people independently look at the same evidence and come to the same conclusion, this reinforces the credibility of that conclusion

26. Describe how an adaptation, such as better running speed, relates to natural selection.

- a. Natural selection produces beneficial adaptations, such as better running speed, in individuals that run more frequently
- b. Natural selection randomly mutates individuals' genetic code until it produces beneficial adaptations, such as better running speed
- c. Natural selection produces adaptations, such as better running speed, to help individuals survive and reproduce
- d. Natural selection reproduces individuals with favorable genetic traits—such as the adaptation of better running speed—over time.

27. Give an example of convergent evolution and explain how it supports the theory of evolution by natural selection.

a. An example of convergent evolution is the development of the same function, swimming, in organisms that live in different parts of the globe, such as Arctic beluga whales and Antarctic right whales. The fact that organisms that do not come in contact with each other have developed the same traits suggests that natural selection can produce similar adaptations in organisms who share a similar environment

b. An example of convergent evolution is the set of adaptations, such as better running speed or more efficient hunting, developed by a species in response to competition with a new species that moves into the same region. The fact that a species adapts after it comes into contact with a competitor suggests that natural selection works more quickly with higher selective pressures.

c. An example of convergent evolution is the development of an ancestral structure, a limb, into two different modern structures, such as a hand and a flipper. The fact that natural selection can cause a structure to develop down two different pathways due to different environmental conditions supports the theory of evolution

d. An example of convergent evolution is the development of the same function, flying, in organisms that do not share a recent common ancestry, such as insects and birds. The fact that wings that allow flight have developed from very different original structures suggests that the process of natural selection can produce similar adaptations in two very different types of organisms who share a similar environment

28. Why do scientists consider vestigial structures evidence for evolution?

- a. Vestigial structures are the result of convergent evolution, so they are good evidence that natural selection act similarly in similar environmental conditions.
- b. Vestigial structures are the result of common ancestry, so they are good evidence that different populations of organisms evolved from a common point.
- c. Vestigial structures are the result of convergent evolution, so they are good evidence for an end goal to evolution.
- d. Vestigial structures are the result of common ancestry, so they are good evidence for a common origin of all life.

29. Reproduction in sexually-reproducing organisms occurs when two sex cells, or gametes, fuse. In fish, this occurs when sperm swim through the water to find the ovum. In flowers, pollen is dispersed through the air and carried to another flower. Explain what evolutionary

adaptations for reproduction occur in humans, based on the fact that we are land-based animals.

30. While examining the human genome, you find a gene that is not homologous to any other organisms known to man. You conclude that this gene must be unique to the human species and could not have evolved from another organism. Would this discovery suggest that humans do not share a common ancestor with all other organisms on Earth? Explain your answer.

31. Mutations in the glucose 6-phosphate dehydrogenase (G6PD) gene can cause a rare anemia when inherited.

However, homozygotes with this mutation are less prone to malaria infection, a disease that historically was the most widespread deadly disease among humans. Predict how this mutation would affect the fitness of individuals living in countries where malaria is endemic.

32. How does the scientific meaning of “theory” differ from the common vernacular meaning?

- A scientific theory is a hypothesis that needs to be tested, whereas people often use theory to mean a simple guess.
- A scientific theory is a statement that has been proven correct, while people often use it to mean a statement that has not yet been verified.
- A scientific theory is a thoroughly tested set of explanations for a body of observations of nature, while people often use it to mean a guess or speculation.
- A scientific theory is a random guess, while people often use it to mean a statement that is somewhat based in fact.

33. Why is having a way of defining species and distinguishing between them important for the study of evolution?

- A distinction between species allows scientists to understand the common origin of all species.
- A common definition of species allows scientists to agree on all aspects of the theory of evolution.
- Divergence can only occur at the species level: it does not occur to larger taxa. Therefore it is important to know which groups are distinct species.
- In the study of evolution, the species is the unit over which change is measured.

34. If a population stopped reproducing sexually, but still reproduced asexually, how would its genetic variation be affected over time? Could speciation occur in this situation? Explain your ideas.

- Genetic variation would increase and speciation would be possible
- Genetic variation would increase and speciation would not be possible.
- Genetic variation would decrease and speciation would be possible.
- Genetic variation would decrease and speciation would not be possible.

35. What role do prezygotic and postzygotic barriers play in speciation?

- Prezygotic and postzygotic barriers allow for the formation of less-fit hybrids that reinforces speciation.
- Prezygotic and postzygotic barriers prevent interbreeding of species such that there is no gene flow between them.
- Prezygotic and postzygotic barriers prevent migration of the two species, causing them to remain in contact with each other and begin to interbreed.
- Prezygotic and postzygotic barriers are present only in newly-formed species, allowing scientists to identify the time of divergence of the species.

36. A population of flowers was separated into two subpopulations when a new river cut through the plain in which they were growing. The number of interbreeding events per year for the two subpopulations of flowers is shown in the graph below. Twenty-four years after they were separated, can you conclude that the two subpopulations of flowers have become new species? Why or why not?

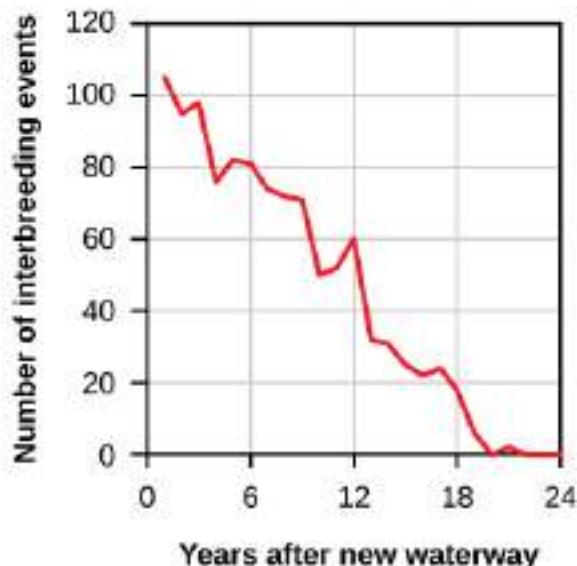

Figure 18.26

37. Which type of speciation, allopatric or sympatric, is

more common? Why?

- Allopatric speciation is more common because it prevents gene flow between the species.
- Allopatric speciation is more common because it involves stronger prezygotic barriers.
- Sympatric speciation is more common because it prevents gene flow between the species.
- Sympatric speciation is more common because it involves stronger prezygotic barriers.

38. Use adaptive radiation to explain the diversification of the finches Darwin observed in the Galapagos.

- The finches likely shared a common ancestor when they came to the island, but exhibited different traits. Each species of finch settled the island where its particular traits would be the most adaptive.
- The finches likely originated as one parent species, but over time mutations caused them to develop reproductive barriers and separate into different species. To reduce competition, the species then radiated out to inhabit different islands.
- The finches likely dispersed from one parent species, and natural selection based on different food sources in differing habitats led to adaptive changes, evidenced in the different beak shapes of the different species—each suited to a different food type.
- It is likely that a series of cataclysmic events caused an original finch species to diverge into the many finch species that inhabited the islands when Darwin observed them. The different species then radiated out to the different islands and adapted to the different conditions on each.

39. Describe a situation where hybrid reproduction would cause two species to fuse into one.

- Separate species cannot interbreed, so hybrid reproduction does not occur in nature
- If the hybrid offspring are more fit than the parents, reproduction would likely continue between both species and the hybrids, eventually bringing all organisms under the umbrella of one species
- Two species that have recently diverged from each other can reproduce with each other, creating hybrid individuals that belong to the species of the parents' common ancestor.
- If two species occupy the same niche in the same area, they can either compete or they can collaborate and reproduce with each other, eventually fusing into a single species

40. What do both rate of speciation models have in common? Explain.

- Both models ignore the influence of gene flow for simplicity's sake.
- Both models apply only to island chains.
- Both models require the influence of cataclysmic events which precipitate rapid adaptation and speciation
- Both models conform to the rules of natural selection and the influences of gene flow, genetic drift, and mutation

41. Describe a situation where hybrid reproduction would cause two species to continue divergence.

- If two closely related species continue to produce hybrids, the hybrids will compete with both species, causing them to find new niches which will further their divergence
- If two closely related species continue to produce hybrids, they will develop reproductive barriers to prevent production of hybrids, to ensure that they remain separate species.
- If two closely related species continue to produce hybrids that are less fit than the parent species, there would be reinforcement of divergence.
- If two closely related species continue to produce hybrids they will always converge into a single species

TEST PREP FOR AP® COURSES

42. Prior to 1800 in England, the typical moth of the species *Biston betularia* (peppered moth) had a light pattern. Dark colored moths were rare. By the late 19th century, the light-colored moths were rare, and the moths with dark patterns were abundant.

The cause of this change was hypothesized to be selective predation by birds (J.W. Tutt, 1896). During the industrial

revolution, soot and other wastes from industrial processes killed tree lichens and darkened tree trunks. Thus, prior to the pollution of the industrial revolution, dark moths stood out on light-colored trees and were vulnerable to predators. With the rise of pollution, however, the coloring of moths vulnerable to predators changed to light.

Which of the following aspects of Darwin's theory of

evolution does the story of the peppered moth most clearly illustrate?

- There is competition for resources in an overbred population.
- There is great variability among members of a population.
- There is differential reproduction of individuals with favorable traits.
- The majority of characteristics of organisms are inherited.

43. Prior to 1800 in England, the typical moth of the species *Biston betularia* (peppered moth) had a light pattern. Dark colored moths were rare. By the late 19th century, the light-colored moths were rare, and the moths with dark patterns were abundant.

The cause of this change was hypothesized to be selective predation by birds (J.W. Tutt, 1896). During the industrial revolution, soot and other wastes from industrial processes killed tree lichens and darkened tree trunks. Thus, prior to the pollution of the industrial revolution, dark moths stood out on light-colored trees and were vulnerable to predators. With the rise of pollution, however, the coloring of moths vulnerable to predators changed to light.

In the late 1900s, England cleaned up its air, and pollution decreased. The bark of trees went from dark to light.

Which of the following outcomes to the populations of peppered moth would you expect given this environmental change?

- An increase in the number of dark moths and a decrease in the number of light moths
- an increase in the number of moths overall
- an approximately equal number of light moths and dark moths
- an increase in the number of light moths and a decrease in the number of dark moths

44. Prior to 1800 in England, the typical moth of the species *Biston betularia* (peppered moth) had a light pattern. Dark colored moths were rare. By the late 19th century, the light-colored moths were rare, and the moths with dark patterns were abundant.

The cause of this change was hypothesized to be selective predation by birds (J.W. Tutt, 1896). During the industrial revolution, soot and other wastes from industrial processes killed tree lichens and darkened tree trunks. Thus, prior to the pollution of the industrial revolution, dark moths stood out on light-colored trees and were vulnerable to predators. With the rise of pollution, however, the coloring of moths vulnerable to predators changed to light.

Commonly used in biology textbooks, the peppered moth is a classic example of evolutionary change in action. The example describes changes in a population's allele frequencies—a small-scale change, evolutionarily speaking. The presence of both light and dark forms within the gene

pool is demonstrated by the story, but the peppered moth stays a peppered moth.

Which scenario, if it were to occur, would be a model for large-scale evolutionary change?

- Conditions change such that the dark form of the moth is favored and the light form is diminished in the population due to predation. Conditions change again, the dark form is vulnerable, and the light form returns to prevalence.
- Conditions change such that the dark form of the moth is favored and the light form is eradicated in the population due to predation. Conditions change again, the dark form is vulnerable, and the dark form is eradicated due to predation.
- Conditions change such that dark form of the moth is favored and the light form is diminished in the population due to predation. Conditions change again, and both forms have equal prevalence.
- Conditions change such that dark form of the moth is favored and the light form is eradicated in the population due to predation. Conditions change again, the dark form is vulnerable. It develops an adaptation that shields it from predation.

45. Given your understanding of evolutionary theory and the relationship between evolution and the genetic makeup of populations, which statement is false?

- Homologous characteristics that have evolved more recently are shared only within smaller groups of organisms.
- The genetic code is a homologous characteristic shared by all species because they share a common ancestor in the deep past.
- DNA sequence data would likely support any evolutionary tree drawn from anatomical data sets.
- The degree of relatedness between groups of organisms is only sometimes reflected in the similarity of their DNA sequences.

46. Each of the following observations comes from a different scientific discipline. Which is the best support for Darwin's concept of descent with modification?

- a. Geologists provide evidence that earthquakes reshape life by causing mass extinctions.
 - b. Botanists provide evidence that South American temperate plants have more in common with South American tropical plants than temperate plants from Europe.
 - c. Zoologists provide evidence that fewer animal species live on islands than on nearby mainlands.
 - d. Ecologists provide evidence that species diversity increases closer to the equator.
- 47.** Paleontologists have recovered a fossil for an organism named *Archaeopteryx*. It has many features in common with reptiles, but, like birds, shows evidence of feathers. For what aspect of evolutionary theory does this piece of evidence suggest support?
- a. Modern species are distinct natural entities.
 - b. Modern species are not currently evolving.
 - c. Modern species share a common ancestor.
 - d. Modern species have both convergent and divergent traits.
- 48.** Which of the following pieces of evidence illustrates evolution as an ongoing process?
- a. Some genes from the bacterium *E. coli* have sequences that are similar to genes found in humans.
 - b. Marsupial mammals live in just a few places in the world today—Australia, South America, and part of North America.
 - c. The fossil record shows that Rodhocetus, an aquatic mammal related to whales, had a type of ankle bone that is otherwise unique to a group of land animals.
 - d. In the 1940s, infections by the bacterium *Staphylococcus aureus* could be treated with penicillin; today populations exist that are completely resistant.
- 49.** The process of mutation, which generates genetic variation, is random. Thus, life has evolved, and continues to evolve, randomly. Which statement is an appropriately evidence-based refinement of the above?
- a. The process of mutation, which generates genetic variation, is random. However, the process of natural selection, which results in adaptations like the fit between a flower and its pollinator, favors variants which are better able to survive and reproduce. Natural selection is not random, so the overall process of evolution is not random, either.
 - b. The process of mutation, which generates genetic variation, is random. However, the process of migration, which results in gene flow between populations, also generates genetic variation. Migration is not random, so the overall process of evolution is not random, either.
 - c. The process of mutation, which generates genetic variation, is random. However, the process of sexual reproduction, which also introduces genetic variance, is not random. Because sexual reproduction is not random, the overall process of evolution is not random, either.
 - d. The process of mutation, which generates genetic variation, is random. Whether mutations have a positive, negative, or neutral effect in terms of selective advantage is also random. Mutations and their effects are random, so the overall process of evolution is random.
- 50.** The selective breeding of plants and animals that possess desired traits is a process called artificial selection. For example, broccoli, cabbage, and kale are all vegetables that have been selected from one species of wild mustard. How is artificial selection both similar to and different from Darwin's conception of natural selection? Does artificial selection provide evidence for evolution by natural selection? Explain.

- a. Both artificial selection and natural selection are the differential reproduction of individual organisms with favored traits. In artificial selection, humans have actively modified plants and animals by selecting and breeding individuals with traits deemed desirable. In natural selection, the most successful individuals in a species are selected by the species to reproduce
- b. Both artificial selection and natural selection are processes that result in better-adapted individuals within a species. In artificial selection, humans have actively modified plants and animals by selecting beneficial genes from other organisms and inserting them into the target organisms. In natural selection, natural processes such as mutations and viruses introduce new genes to a population
- c. Both artificial selection and natural selection are processes that cause organisms to be better adapted over time. In artificial selection, humans have trained animals to be more successful in completing tasks that the humans want completed. In natural selection, organisms train the functions that they will need to survive and reproduce
- d. Both artificial selection and natural selection are the differential reproduction of individual organisms with favored traits. In artificial selection, humans have actively modified plants and animals by selecting and breeding individuals with traits deemed desirable. In natural selection, individuals are selected naturally as its traits deem it more fit for survival and reproduction

51. Genes important in the embryonic development of animals have been relatively well conserved during evolution. This means they are more similar among different species than many other genes. What explains this genetic conservation across animal species?

- a. Changes in the genes that are important to embryonic development have been relatively minor because there are no selective pressures on an individual before it is born
- b. Changes in the genes that are important to embryonic development have been relatively minor because not much time has elapsed since the divergence of the various animal taxa.
- c. Changes in the genes that are important to embryonic development have been relatively minor because early embryos are very fragile and even small mutations can result in death
- d. Changes in the genes that are important to embryonic development have been relatively minor because mutational tweaking in the embryo has magnified consequences in the adult

52. The upper forelimbs of humans and cats have fairly similar structures. In contrast, the upper forelimbs of whales (their flippers) have bones with a different shape and proportion from both cats and humans. Interestingly, genetic data suggests that all three organisms have a common ancestor from about the same point in time. What is a likely explanation for these data?

- a. Cats and humans are more closely related to each other than either are to whales.
- b. The shape of the whale forelimb arose as a result of disadvantageous mutations
- c. The whale flipper is an adaptive characteristic unique to its water environment.
- d. The whale flipper is a vestigial structure.

53. Biogeography is the study of biological species as they relate to geographical space and geological time. The fossil record shows that dinosaurs originated about 200 to 250 million years ago. Would you expect the geographic distribution of early dinosaur fossils to be broad (on many continents) or narrow (on one or a few continents)? Explain.

- a. broad because dinosaurs originated before the breakup of Pangaea
- b. broad because some dinosaurs could fly between continents
- c. narrow because they went extinct too quickly to disperse very far
- d. narrow because they lived so long ago that the fossils have mostly broken down or disappeared

54. The term microevolution describes evolution on its smallest scale: the change in allele frequencies in a population over generations. DDT is a pesticide that was widely in use in the United States from the 1940s until 1972. The table below summarizes a particular allele frequency in laboratory strains of the common fruit fly, *Drosophila melanogaster*.

Strains collected from flies in the wild in the 1930s	Strains collected from flies in the wild in the 1960s
Frequency of allele conferring DDT resistance	0% 40%

Using this information, describe a model in which natural selection improved the match between *D. melanogaster* and its environment through microevolution.

- a. DDT killed off a large proportion of the population, and the alleles present in the surviving fruit flies differed from those in the original population
- b. Mutations from the application of DDT caused the allele conferring DDT resistance to appear in the population.
- c. Female mosquitoes chose to mate with male mosquitoes that had the allele conferring DDT resistance because it would make their offspring more fit.
- d. The wide use of DDT meant that fruit flies with DDT resistance were more evolutionarily fit than their counterparts without DDT resistance.

55. In 1795, a Scottish geologist named Charles Hutton suggested that Earth's geologic features could be explained by gradual processes that were still operating. This was in direct contrast to other scientific thought at the time, which included well-accepted proposals that geologic layers were representative of catastrophic events caused by processes no longer operating in the present time. Hutton proposed geologic features as the result of slow and consistent change, such as valleys formed by rivers wearing through rock. Hutton's ideas were incorporated in the work of Charles Lyell, a geologist working in Darwin's time. Lyell advocated a principle called uniformitarianism, the consistency of mechanisms of change over time. In other words, Lyell argued that the same geologic processes operating in the present had operated in the past, and at the same rate.

The ideas of Hutton and Lyell influenced the work of Charles Darwin. How do Hutton's and Lyell's ideas connect to and provide support for Darwin's theory of evolutionary change?

- a. The idea that the same processes that operate in the present also operated in the past, and at the same rate, supported Darwin's hypothesis of natural selection because humans could select for desirable traits and produce change very rapidly, so natural selection would also be fast enough to produce the full range of diversity in living organisms.
- b. The idea that the same processes that operate in the present also operated in the past, and at the same rate, connects to Darwin's hypothesis of natural selection because he had observed it happening in the present
- c. The idea that geologic change is the result of slow, continuous processes rather than sudden, substantial change connects to Darwin's support of gradualism rather than punctuated equilibrium as the process that guided evolution.
- d. The idea that geologic change is the result of slow, continuous processes rather than sudden, substantial change connects directly to Darwin's hypothesis that, given enough time, slow and subtle processes could produce substantial biological change.

56. The human immunodeficiency virus (HIV) reproduces very quickly. A single virus can replicate itself a billion times in one 24-hour period. In a hypothetical treatment situation, a patient's HIV population consists entirely of drug-resistant viruses after just a few weeks of treatment. How can this treatment result best be explained? How does this explanation illustrate that evolution is an ongoing process?

- a. The resistant viruses passed their genes to the non-resistant viruses so that 100% of the viruses became resistant. This illustrates evolution as an ongoing process because the genes of the population changed in real time.
- b. The non-resistant viruses died, and the resistant ones survived and rapidly reproduced. This illustrates evolution as an ongoing process because the change in the HIV population is the result of natural selection.
- c. The viruses developed resistance to the drug after repeated exposure to it. This illustrates evolution as an ongoing process because the viruses were able to adapt to changing conditions.
- d. The drug-resistant viruses were more fit than their non-resistant counterparts to begin with, and over time they dominated the population. This illustrates evolution as an ongoing process because natural selection favored one phenotype over another.

57. A friend says: "Natural selection is about the survival of the very fittest in a population. The fittest are those that

are strongest, largest, fastest."

Would you agree with that statement? Explain. What evidence from scientific disciplines can you offer to support your agreement or your disagreement?

- The statement is true. If an organism is not strong and fast, it will not survive long enough to reproduce and pass on its genes, and if it is not large and fitter than the other individuals around it then it will not be able to compete for a mate. Many seal species, for example, have only a single male who gets to mate. He must be the very fittest seal to win all the females.
- The very fittest organisms are not necessarily the ones that survive. Sometimes it is the least fit organisms that survive and reproduce. For example, in one generation the mice who are bad at foraging for seeds may reproduce prolifically and dominate the mice who are good at foraging. In this case, natural selection will select for the less-fit phenotype and spread it in the population.
- The definition of fitness is not correct. The strongest and fastest organisms are more fit than the weaker and slower ones, but large individuals are often at a disadvantage to smaller ones because they are easily spotted by predators. For example, a large rabbit will stick out on a field more than a small one and will get eaten by a hawk.
- What is meant by "fittest" is not necessarily strong, large, and fast. Fitness, as defined in evolutionary terms, has to do with survival and the reproduction of genetic material. For example, a small but showy male bird may be selected by female birds to reproduce, while a large but less colorful one is not.

- 58.** A student placed 20 tobacco seeds of the same species on moist paper towels in each of two petri dishes. Dish A was wrapped completely in an opaque cover to exclude all light. Dish B was not wrapped. The dishes were placed equidistant from a light source set to a cycle of 14 hours of light and 10 hours of dark. All other conditions were the same for both dishes. The dishes were examined after 7 days, and the opaque cover was permanently removed from dish A. Both dishes were returned to the light and examined again at 14 days. The following data were obtained:

	Dish A	
	Day 7 covered	Day 14 uncovered
Germinated seeds	12	20
Green-leaved seedlings	0	14
Yellow-leaved seedlings	12	6
Mean stem length below first set of leaves	8 mm	9 mm

	Dish B	
	Day 7 uncovered	Day 14 covered
Germinated seeds	20	20
Green-leaved seedlings	15	15
Yellow-leaved seedlings	5	5
Mean stem length below first set of leaves	3 mm	3 mm

Figure 18.27

Which of the following best supports the hypothesis that the difference in leaf color is genetically controlled?

- the number of yellow-leaved seedlings in dish A on day 7
- the number of germinated seeds in dish A on days 7 and 14
- the death of all the yellow-leaved seedlings
- the existence of yellow-leaved seedlings as well as green-leaved ones on day 14 in dish B

- 59.** Use the data from **Figure 18.27** to answer the question. Which best describes the usefulness of the yellow-leaved phenotype as a variation subject to natural selection?

- a. the yellow-leaved phenotype can germinate in environments without light
- b. the germination of the yellow-leaved phenotype is unaffected by light intensity
- c. the germination of the yellow-leaved phenotype is accelerated as compared to the green-leaved phenotype
- d. the yellow-leaved phenotype cannot germinate in environments with light

60. Use the data from **Figure 18.27** to answer the question. Yellow-leaved seedlings are unable to convert light energy to chemical energy. Which observation is most likely to be made on day 21?

- a. a few yellow-leaved seedlings alive in dish A, but none in dish B
- b. a few yellow-leaved seedlings alive in dish B, but none in dish A
- c. no yellow-leaved seedlings alive in dish A or dish B
- d. a few yellow-leaved seedlings alive in dish A and dish B

61. Populations of a nocturnal toad live along a long river. On the other side of a band of territory that is about 10 kilometers wide, there are populations of a toad that appear similar. Which of the following data would provide compelling evidence that the two populations represent different species?

- a. The populations of toads on the other side of the banded territory are not completely nocturnal.
- b. Fertile hybrid populations of toads are found between the two other populations.
- c. There appear to be some hybrid toads between the two populations, but they are few and frail.
- d. The two populations of toads enact very different mating behaviors.

62.

Mass Extinction	Time of Extinction	Organisms Greatly Reduced or Made Extinct
End of the Ordovician period	443 million years ago	Trilobites, brachiopods, echinoderms, and corals
End of the Devonian period	354 million years ago	Marine families on tropical reefs, corals, brachiopods, and bivalves
End of the Permian period	248 million years ago	Trilobites, mollusks, brachiopods, and many vertebrates
End of the Triassic period	206 million years ago	Mollusks, sponges, marine vertebrates, and large amphibians
End of the Cretaceous period	65 million years ago	Ammonites, dinosaurs, brachiopods, bivalves, and echinoderms

>

- a. searching horizontal rock layers in any class of rock and trying to find those that contain the greatest number of fossils
- b. collecting fossils from rock layers deposited prior to the Permian period that contain some early vertebrate bones
- c. looking in sedimentary layers next to bodies of water in order to find marine fossils of bivalves and trilobites
- d. using relative dating techniques to determine the geological ages of the fossils found so they can calculate the rate of speciation of early organisms

63. Populations of a plant species have been found growing in the mountains at altitudes above 2,500 meters. Populations of a plant that appears similar, with slight differences, have been found in the same mountains at altitudes below 2,300 meters.

Describe a plan for collecting two kinds of data that could provide a direct answer to the question: do the populations growing above 2,500 meters and the populations growing below 2,300 meters represent a single species?

- a. Scientists could take the genetic code of a plant from each altitude and determine whether the two sets of DNA are identical. They could also insert genes from one plant into the cells from the other and see if the cells survive
- b. Scientists could look in the fossil record to find the plants' most recent common ancestor. They could also check the surrounding mountains to determine if the most recent common ancestor is still living.
- c. Scientists could breed the two groups in the same environment and observe whether, over several generations, they begin to look more similar. They could also switch the groups, growing the high-altitude plants at low altitude and the low-altitude plants at high altitude, and observe whether the former begin to look like low-altitude plants and the latter begin to look like high-altitude plants.
- d. Scientists could collect seeds and test whether they might be cross-pollinated to produce fertile offspring. They could also investigate the area between 2,500 meters and 2,300 meters to see if fertile hybrid populations might be found living between the two other populations of plants.

64. Populations of a plant species have been found growing in the mountains at altitudes above 2,500 meters. Populations of a plant that appears similar, with slight differences, have been found in the same mountains at altitudes below 2,300 meters.

Explain how the two types of data you suggested provide a direct answer to the question of whether speciation has

taken place.

- a. If the plants become more similar when grown in the same environment, or if the high-altitude plants respond to low altitude in the same way that low-altitude plants have, and low-altitude plants respond to high altitude the same way that high-altitude plants have, then the two groups have the same underlying genetic structure and belong to one species.
 - b. If the seeds from the plants can be cross fertilized and developed into fertile offspring, the two populations are not yet reproductively isolated and remain one species. If hybrid forms are found, the two populations are not reproductively isolated and hybrids are both viable and successful.
 - c. If the genetic codes of the two plants are identical, then they must belong to the same species. Also, if genes transplanted between the plants function successfully, then the plants must be similar enough to each other to belong to the same species.
 - d. If scientists are able to find the common ancestor of the two groups in the fossil record or in neighboring communities, then they can determine whether the plants have diverged into separate species or remain a single species.
- 65.** Assuming a population that has genetic variation and is under the influence of natural selection, place the following events in the order in which they would occur:
- Genetic frequencies within the population change.
 - A change occurs in the population's environment.
 - Phenotypic variations shift.
 - Individuals who are well-adapted leave more offspring than individuals who are poorly adapted.
 - Individuals who are poorly adapted do not survive at the same rate as individuals who are well adapted.
- a. 1. A change occurs in the population's environment.
2. Individuals who are poorly adapted do not survive at the same rate as individuals who are well adapted.
3. Individuals who are well-adapted leave more offspring than individuals who are poorly adapted.
4. Genetic frequencies within the population change.
5. Phenotypic variations shift.
 - b. 1. A change occurs in the population's environment.
2. Genetic frequencies within the population change.
3. Phenotypic variations shift.
4. Individuals who are poorly adapted do not survive at the same rate as individuals who are well adapted.
5. Individuals who are well-adapted leave more offspring than individuals who are poorly adapted.
 - c. 1. Phenotypic variations shift.
2. A change occurs in the population's environment.
3. Genetic frequencies within the population change.
4. Individuals who are poorly adapted do not survive at the same rate as individuals who are well adapted.
5. Individuals who are well-adapted leave more offspring than individuals who are poorly adapted.
 - d. 1. Individuals who are well-adapted leave more offspring than individuals who are poorly adapted.
2. Individuals who are poorly adapted do not survive at the same rate as individuals who are well adapted.
3. Phenotypic variations shift.
4. Genetic frequencies within the population change.
5. A change occurs in the population's environment.
- 66.** A biologist studies a population of voles for 20 years. During almost the entire research period, the population stays between 50 and 75 individuals. Additionally, fewer than half of the voles born do not survive to reproduce, due to predation and competition for food. Then, in one generation, 80% of the voles born live to reproduce. The population increases to 110 individuals. What inferences

about food and predation can you make for the singular generation in which 80% of offspring survived? What prediction can you make about the genetic and phenotypic variation of future populations for this group of voles?

- Either there was fewer food available or the degree of predation increased. The future generations of this group of voles should evidence fewer genetic variation.
- Either there was fewer food available or the degree of predation increased. The future generations of this group of voles should evidence greater genetic variation.
- Either there was more food available or the degree of predation decreased. The future generations of this group of voles should evidence less genetic variation.
- Either there was more food available or the degree of predation decreased. The future generations of this group of voles should evidence greater genetic variation.

67. There are years of drought in a small, relatively isolated community. During the drought, small seeds with thin shells become rare. Large seeds with hard cases become increasingly common. The large, tough seeds are successfully eaten by birds with large and broad beaks. Assuming that the drought continues and the population of birds in the community stays isolated, what predictions for the population can you make under the influence of natural selection?

- The birds with small, thin beaks will grow larger, broader beaks to be able to eat the larger seeds. This will result in subsequent generations having a higher percentage of birds with large, broad beaks.
- There will be more birds with small, thin beaks dying and more birds with large, broad beaks surviving. Differential reproduction of birds with large, broad beaks will result in subsequent generations having a higher percentage of birds with large, broad beaks.
- The species will diverge into two species, one with small, thin beaks and one with large, broad beaks. The two species will then compete for resources.
- There will be neither phenotypic nor genotypic changes in the population.

68. At one time, avian researchers in the Sulawesi region of Indonesia described the Flowerpecker populations on the mainland and the Wakatobi archipelago as one species. A recent reassessment of the Wakatobi populations resulted in the suggested reclassification of these populations as a distinct species, the Wakatobi Flowerpecker. Which of the following pieces of evidence, if true, would be cause for this reclassification?

- The populations have become dependent on the island food sources.
- The populations have become morphologically distinct from the mainland species.
- The populations have become adapted to the island habitat.
- The populations have become reproductively isolated from the mainland species.

69. What pattern in the fossil record would you expect to see to support the model of gradual speciation? How would you expect this pattern to differ from a pattern in the fossil record that supports the model of punctuated equilibrium? Explain.

- In the case of gradual speciation, the fossil record would show only a few hybrid individuals, followed by individuals of the two distinct species. For the case of punctuated equilibrium, the fossil record would show many hybrid individuals persisting through several geological layers.
- In the case of gradual speciation, the fossil record would show the parent species in a single location, such that the newly diverged species remained in contact with each other. For the case of punctuated equilibrium, the fossil record would show a geographic divide within the parent species that caused it to diverge into multiple new species.
- In the case of gradual speciation, the fossil record would show many intermediate forms. For the case of punctuated equilibrium, the fossil record would show new forms that persist essentially unchanged through several geological layers, then disappear just as a new form appears.
- Gradual speciation would be undetectable in the fossil record. For the case of punctuated equilibrium, the fossil record would show a steady progression of distinct forms.

70. Until recently, these three species of short-tailed pythons, *Python curtus*, *Python brongersmai* (middle), and *Python breitensteini* were considered one species. However, due to the different locations in which they are found, they have become three distinct species. What is this an example of?

- divergent evolution
- sympatric speciation
- allopatric speciation
- variation

71. Consider two species of birds that diverged while separated geographically but resumed their contact before reproductive isolation was complete. Which describes the first step in what would happen over time if the two

species mated extensively and their hybrid offspring survived and reproduced more poorly than offspring from intra-species matings?

- Natural selection would cause prezygotic barriers to reproduction between the parent species to strengthen over time.
- The production of unfit hybrids would increase and the speciation process would complete.
- The extensive mating between the species would continue to produce large numbers of hybrids.
- The gene pools of the parent species would fuse over time, reversing the speciation process.

SCIENCE PRACTICE CHALLENGE QUESTIONS

72. In addition to biology, evidence drawn from many different disciplines, including chemistry, geology, and mathematics, supports models of the origin of life on Earth. In order to determine when the first forms of life likely formed, the rate of radioactive decay can be used to determine the age of the oldest rocks (see optional problems C and D, below) exposed on Earth's surface. These are found to be approximately 3.5 billion years old. The age of rocks can be correlated to fossils of the earliest forms of life.

A. The graph compares times of divergence from the last common ancestor based on the fossil record with a "molecular time" constructed by comparing sequences of conserved proteins to determine a mutation rate (after Hedges and Kumar, *Trends in Genetics*, 2003). Explain how such a molecular clock could be refined to infer time for the evolution of prokaryotes.

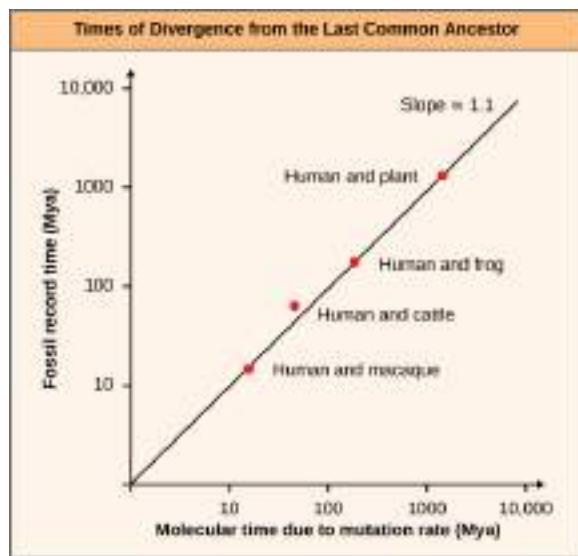

Figure 18.28

B. Using a molecular clock constructed from 32 conserved proteins, Hedges and colleagues (Battistuzzi et al., *BMC Evol. Biol.* 2004) estimated the times during which key biological processes evolved. A diagram based on their work is shown. Connect the time of the origin of life inferred from this diagram with the age of the oldest fossil

stromatolites and the age of the oldest exposed rock to show how evidence from different scientific disciplines provides support for the concept of evolution. Evaluate the legitimacy of claims drawn from these different disciplines (biology, geology, and mathematics) regarding the origin of life on Earth.

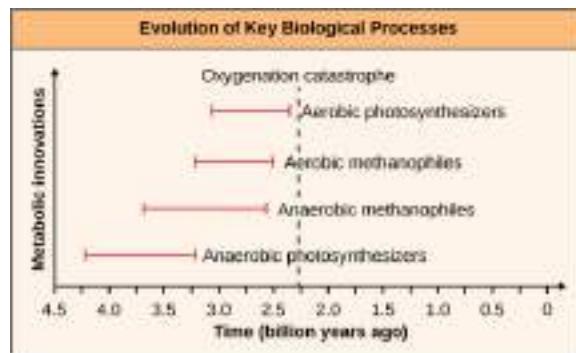

Figure 18.29

The oldest known rocks are exposed at three locations: Greenland, Australia, and Swaziland. The following application of mathematical methods provides the essential evidence of the minimum age of Earth. The mathematics is appropriate for students who have completed a second year of algebra. However, it is not illustrative of the type of item that could appear on the AP Biology Exam.

The exposed rocks contain a radioactive isotope of rubidium, ^{87}Rb , which decays into a stable isotope of strontium, ^{87}Sr . An ^{87}Rb atom with 37 protons and 50 neutrons decays when a proton is converted into a neutron to produce an atom, ^{87}Sr , with 36 protons and 51 neutrons. As time passed, the number of each isotope changed from its initial value. When a crystal containing ^{87}Rb atoms formed from the molten surface of the hot, early Earth during the Hadean eon, the number of these atoms at that initial time can be represented as $N_{87\text{Rb},0}$. As time passed, the number of atoms of this isotope changed to $N_{87\text{Rb}}$.

C. Justify the relationship between the number of each isotope at any time and the number of each at the time that the molten rock solidified (denoted by the subscript 0):

$$N_{87\text{Sr}} = N_{87\text{Sr},0} + N_{87\text{Rb},0} - N_{87\text{Rb}}$$

The decay of unstable radioisotopes is exponential with a half-life of $T_{1/2}$, which for ^{87}Rb is 4.88×10^{10} years:

$$N_{87\text{Rb}} = N_{87\text{Rb}, 0} e^{-0.693t / T_{1/2}}$$

This can be used to replace the initial number of ^{87}Rb atoms, which cannot be measured, with the present-day value:

$$\frac{N_{87\text{Sr}}}{N_{86\text{Sr}}} = \frac{N_{87\text{Sr}, 0}}{N_{86\text{Sr}}} + (e^{-0.693t / T_{1/2}} - 1) \frac{N_{87\text{Rb}}}{N_{86\text{Sr}}}$$

When the measurements of the numbers of ^{87}Rb and ^{87}Sr were made (Moorbath et al., *Nature*, 1972), measurements of a second stable isotope of strontium, ^{86}Sr , were also made. The ratio of the initial number of ^{87}Sr and ^{86}Sr atoms is the same as today, since the isotopes are both stable. The value of this ratio is 0.71.

This is a linear equation in the form $y = ax + b$, where a is the term in parenthesis containing the half-life of ^{87}Rb . If

$$Y = N_{87\text{Sr}} / N_{86\text{Sr}}$$

is graphed versus $N_{87\text{Rb}} / N_{86\text{Sr}}$, the slope can be used to determine the time, t , that has passed since the rock formed from melting:

$$a = e^{0.693t / T_{1/2}} - 1, \text{ so}$$

$$t = \ln(a + 1) \cdot T_{1/2} / 0.693$$

D. Data on the rubidium and strontium isotopes at Isua in Greenland are provided in the table. **Analyze** these data to obtain the age of formation of these rocks.

Table 18.1

The solidification of the molten surface of Earth at the end of the Hadean eon (4 to 4.6 billion years ago) and the condensation of liquid oceans provided a medium from which life emerged. The most ancient fossils are colonial, photosynthetic cyanobacteria called stromatolites. As climate change melted the perennial snow covering Greenland, new geologic evidence of the time of that origin was obtained (Nutman et al., *Nature* 2016) with the

discovery of the most ancient stromatolites. These fossils record communities of photosynthetic bacteria embedded in Isua sediments 3.7 billion years ago. Worldwide stromatolite fossils show a decline between 1 and 1.3 billion years ago.

73. In 1952, the Miller-Urey experiment showed that an electrical discharge in a gas-phase mixture of ammonia, hydrogen, methane, and water produced five amino acids. When the experiment was conducted, evidence indicated that this mixture was representative of the Hadean (early Earth) atmosphere. The experiment was repeated in the presence of jets of hot steam, simulating Hadean volcanic eruptions and producing an even larger variety of amino acids.

A. Consider the following criticisms of the “organic soup” model and **justify the selection of data** that other experiments might provide regarding the origin of life on Earth.

- Biopolymers on Earth have a left-hand symmetry at the carbon adjacent to the carboxylic acid carbon, and these experiments produced mixtures of both left- and right-hand symmetries.
- No peptide bonds between amino acids were observed.
- Early Earth’s atmospheric oxygen concentration is known to have been very low, implying the absence of an ozone layer to filter high-energy ultraviolet (uv) radiation.
- Ammonia decomposes when it absorbs high-energy uv radiation, but diatomic nitrogen does not.

Models of the abiotic synthesis of biomolecules suffer from a “chicken and egg” dilemma. Proteins are needed to synthesize DNA and RNA, and DNA and RNA are needed to synthesize proteins. Which molecules came first?

B. In light of the following observations, **evaluate the hypothesis** that nucleotides arose from a prebiotic mixture.

- Nucleic acids are not found in experiments like those of Miller and Urey.
- Purines and pyrimidines decompose at high temperature, and Earth was bombarded by meteors and comets during the Hadean eon.
- Bonds in the purine and pyrimidine rings of nucleic acids are broken by high-energy uv radiation.
- Carl Sagan and colleagues synthesized ATP from a mixture of adenosine, ribose, and phosphate when exposed to uv radiation.
- Ribose has never been synthesized in experiments like those conducted by Miller and Urey.
- Ribose has a left/right symmetry, and the right-handed form occurs in Earth organisms.

Continuing with the analogy, if neither the chicken nor the egg came first, then both must have arisen together. Some

regard simultaneous innovations in both catalysis and information storage and retrieval as too improbable. In samples of meteorites, both amino acids and nucleic acids have been found. The amino acids are mixtures of left- and right-handed symmetries, although some have shown a significant bias toward the left-handed form (J. Elisa et al., *ACS Central Science*, 2016). The arrival from space of the seeds of biomolecules is called panspermia. Carl Sagan (1966) and Francis Crick (1973), one of the first to describe the structure of DNA, regarded panspermia as the only plausible origin of life on Earth. In fact, their belief was in directed panspermia, the intentional seeding by intelligent aliens.

C. Describe the questions that must be addressed for panspermia to be a scientific hypothesis about the origin of life on Earth and **describe** the reasons for the directed panspermia revision of this hypothesis.

To avoid the conflicting chicken-and-egg claims that “protein catalyst was first” and “DNA information storage was first,” two alternatives have emerged regarding the origin of life on Earth. Consider two simple ideas: 1) water blocks uv radiation, and cracks in the ocean floor (hot vents) provide a temperature difference that generates a source of entropy; and 2) ribosomes are composed of RNA.

D. Describe one of the following as a hypothesis concerning the origin of life on Earth:

- Reactions among molecules in the vicinity of hot vents became organized in space and time, eventually developing structures that foreshadow the proton gradient upon which metabolism is based. This alternative is the basis for what is referred to as the metabolism-first hypothesis.
- The catalytic properties of the ribosome reflect the self-catalytic polymerization of nucleotides with sequential structures conserved in modern DNA, the catalytic properties conserved in proteins, and the catalytic properties of the ribosome whose core structure is RNA. This alternative is the basis for what is referred to as the RNA-first hypothesis.

74. The radiant energy emitted by a star gradually increases after its birth. During the Hadean eon, while the molten Earth cooled and life emerged, the Sun provided approximately 25% less radiant energy than it does now. Ignoring effects due to differences in the composition of Earth's atmosphere between then and now, this means that the average surface temperature of the surface would be about 25 °C below the freezing temperature of water. Evidence of liquid water on Earth during the Hadean eon is provided by geologic structures known only to form in liquid water, such as lava pillows and the stromatolites that are the fossilized layers of photosynthetic cyanobacteria.

Pose a scientific question that guides inquiry into early Earth conditions that supported the innovation of photosynthesis.

75. Connect the techniques of radiometric measurement,

anatomy, and molecular biology to the supporting evidence of the theory of evolution provided.

76. Describe reasons for the revision of scientific hypotheses of the origin of life on Earth.

77. Directed evolution is an inquiry strategy that is usually used to investigate gene expression or the function of proteins that are expressed. The investigator imposes a selection pressure and observes the evolution of a population. In one investigation, unicellular yeast were allowed to sediment in a column of a nutrient-containing solution. Individuals that traveled furthest towards the bottom of the column were removed and placed in a new column. After 60 generations of repeated selection, yeast became multicellular. In this experiment, selection was acting on the collection of cells and not on the individual. To test the claim that selection was acting on the multicellular system and not just individual cells, the investigators compared the effects on a population of yeast that had acquired multicellularity by strong selection (allowing only 5 minutes to settle) and weak selection (allowing 25 minutes to settle). A strong selection increased cluster size, and a weak selection decreased cluster size.

A. Evaluate the claim that the use of both a strong and weak selection demonstrates that evolution is an ongoing process that, under artificially imposed conditions, led to the emergence of multicellularity in a single-celled organism.

B. In this directed evolution study, the selection pressure imposed by the investigators led to a new phenotype. Consider a situation in which there is a vertical variation in the density of nutritional resources. Analyze the advantages and disadvantages of cooperative behavior, including changes in the likelihood of replication of the individual and population genomes.

78. Selection processes in changing and unchanging environments differ. **Connect** the effects of negative and positive selection pressures to changes in the environment.

79. In biology, the word “race” is rarely used. It could be imagined to be synonymous with a subspecies. Species is well defined, at least when horizontal gene transfer is not taken into account, by reproductive isolation. Speciation may arise through geographic isolation.

A. Aside from geographic isolation leading to reproductive isolation, **predict** two other mechanisms of speciation in a population and how these mechanisms can lead to a scientific definition of a subspecies.

The use of the term “race” with regard to human populations might be a reference to cultural or socioeconomic isolation, and has often been mistaken to have biological significance. Rosenberg et al. (*Science*, 2002) sampled the genes of 1,056 people from 52 populations. They compared genetic variations within each population to variations among populations. They found that differences between individuals in two different

populations were, on average, roughly 20 times smaller than differences between two individuals in the same population.

B. Groups of humans have often been geographically isolated for long periods of time until isolation is broken

by invasion, enslavement, migration, or another similar event. Invaders have traditionally been male. **Predict** the effect of invasion on the differential inheritance of genes in X- and autosomal chromosomes.

19 | THE EVOLUTION OF POPULATIONS

- 19.2: Population Genetics**
- 19.3: Adaptive Evolution**

Introduction

Evolutionary medicine is an emerging field that applies evolutionary theory to modern medicine. Rather than just seeking answers to how illness occurs, evolutionary medicine also asks why illness occurs. This approach to medicine has led to many important advances. For example, endogenous retroviruses (ERVs) are pieces of retroviruses that began invading mammalian genomes over 100 million years ago. While studying why smaller mammals tend to get cancer more frequently than larger mammals, scientists discovered that larger mammals have had fewer ERVs invade their genome. Because retroviral integration is associated with cancer, results from this research suggest the possibility that larger mammals are able to control EVR replication until they reach post-reproductive age.^[1] More on this research can be found on the **PLOS Pathogens website (<http://openstaxcollege.org/l/32mammalcancer>)**.

19.1 | Population Evolution

In this section, you will explore the following questions:

- What is population genetics and how is population genetics a synthesis of Mendelian inheritance and Darwinian evolution?
- What is the Hardy–Weinberg principle, and how can it be applied to microevolution?

The mechanisms of inheritance, or genetics, were not understood at the time Charles Darwin and Alfred Russel Wallace were developing their idea of natural selection. This lack of understanding was a stumbling block to understanding many aspects of evolution. In fact, the predominant (and incorrect) genetic theory of the time, blending inheritance, made it difficult to understand how natural selection might operate. Darwin and Wallace were unaware of the genetics work by Austrian monk Gregor Mendel, which was published in 1866, not long after publication of Darwin's book, *On the Origin of Species*. Mendel's work was rediscovered in the early twentieth century at which time geneticists were rapidly coming to an understanding of the basics of inheritance. Initially, the newly discovered particulate nature of genes made it difficult for biologists to understand how gradual evolution could occur. But over the next few decades genetics and evolution were integrated in what became known as the **modern synthesis**—the coherent understanding of the relationship between natural selection and genetics that took shape by the 1940s and is generally accepted today. In sum, the modern synthesis describes how evolutionary processes, such as natural selection, can affect a population's genetic makeup, and, in turn, how this can result in the gradual evolution of populations and species. The theory also connects this change of a population over time, called **microevolution**, with the processes that gave rise to new species and higher taxonomic groups with widely divergent characters, called **macroevolution**.

Connection for AP® Courses

Population genetics studies microevolution by measuring changes in a population's allele frequencies over time. (Remember that we studied genotypes and allele frequencies when we explored inheritance patterns proposed by Mendel.) For example, scientists examining allele frequencies in a pesticide resistance gene in mosquitoes at Equatorial Guinea found that the frequency of one resistance allele was 6.3%, while a second resistance allele's frequency was 74.6%, and the non-resistance allele's frequency was 19.0%. These three frequencies add up to 100%.^[2] A population's **gene pool** is the sum of all the alleles. If these frequencies do not change over time, the population is said to be in **Hardy–Weinberg principle of equilibrium**—a stable, non-evolving state. However, if a phenotype is favored by natural selection, allele frequencies can change. If this is the case, the population is evolving. Sometimes allele frequencies within a population change randomly with no advantage to the population over existing allele frequencies. This phenomenon is called **genetic drift**. An event that initiates an allele frequency change in an isolated part of the population, which is not typical of the original population, is called the **founder effect**. In **Population Genetics**, we will explore how natural selection, random drift, and founder effects can lead to significant changes in the genome of a population.

Hardy–Weinberg equilibrium reflects a state of constancy in a population's gene pool. In other words, allele frequencies remain stable from generation to generation if certain conditions are met: no mutations, no gene flow, random mating, no genetic drift, and no selection. Because these conditions are rarely met, allele frequencies are typically changing, reflecting evolution. The Hardy–Weinberg principle is represented by the mathematical equation $p^2 + 2pq + q^2 = 1$, where p represents the frequency of the dominant allele and q represents the frequency of the recessive allele. Deviations from Hardy–Weinberg equilibrium allow us to measure microevolutionary shifts in a population when one or more of the Hardy–Weinberg parameters change. For example, if we go back to the study of the frequencies of alleles in a pesticide resistance gene, after an area was treated with pesticides for two years, the resistance alleles increased to 11.1% and 83.3%, respectively, while the non-resistance allele decreased to 5.6%. This indicates that microevolution was occurring.

everyday CONNECTION for AP® Courses

Evolution and Flu Vaccines

Every fall, the media starts reporting on flu vaccinations and potential outbreaks. Scientists, health experts, and institutions determine recommendations for different parts of the population, predict optimal production and inoculation schedules, create vaccines, and set up clinics to provide inoculations. You may think of the annual flu shot as a lot of media hype, an important health protection, or just a briefly uncomfortable prick in your arm. But do you think of it in terms of evolution?

The media hype of annual flu shots is scientifically grounded in our understanding of evolution. Each year, scientists across the globe strive to predict the flu strains that they anticipate being most widespread and harmful in the coming year. This knowledge is based in how flu strains have evolved over time and over the past few flu seasons. Scientists then work to create the most effective vaccine to combat those selected strains. Hundreds of millions of doses are produced in a short period in order to provide vaccinations to key populations at the optimal time.

Because viruses, like the flu, evolve very quickly (especially in evolutionary time), this poses quite a challenge. Viruses mutate and replicate at a fast rate, so the vaccine developed to protect against last year's flu strain may not provide the protection needed against the coming year's strain. Evolution of these viruses means continued adaptions to ensure survival, including adaptations to survive previous vaccines.

Population genetics is the study of what?

- a. How selective forces change the allele frequencies in a population over time.
- b. The genetic basis of genetic traits within individuals.
- c. Whether traits have a genetic basis.
- d. The degree of inbreeding in a population.

Population Genetics

Recall that a gene for a particular character may have several alleles, or variants, that code for different traits associated with that character. For example, in the ABO blood type system in humans, three alleles determine the particular blood-type protein on the surface of red blood cells. Each individual in a population of diploid organisms can only carry two alleles for a particular gene, but more than two may be present in the individuals that make up the population. Mendel followed alleles as they were inherited from parent to offspring. In the early twentieth century, biologists in a field of study known as population genetics began to study how selective forces change a population through changes in allele and genotypic frequencies.

The **allele frequency** (or gene frequency) is the proportion of a specific allele within a population, relative to all other alleles of that gene that are present in the population. Until now we have discussed evolution as a change in the characteristics of a population of organisms, but behind that phenotypic change is genetic change. In population genetics, the term evolution is defined as a change in the frequency of an allele in a population. Using the ABO blood type system as an example, the frequency of one of the alleles, I^A , is the number of copies of that allele divided by all the copies of the ABO gene in the population. For example, a study in Jordan^[3] found a frequency of I^A to be 26.1 percent. The I^B and I^O alleles made up 13.4 percent and 60.5 percent of the alleles respectively, and all of the frequencies added up to 100 percent. A change in this frequency over time would constitute evolution in the population.

The allele frequency within a given population can change depending on environmental factors; therefore, certain alleles become more widespread than others during the process of natural selection. Natural selection can alter the population's genetic makeup; for example, if a given allele confers a phenotype that allows an individual to better survive or have more offspring. Because many of those offspring will also carry the beneficial allele, and often the corresponding phenotype, they will have more offspring of their own that also carry the allele, thus, perpetuating the cycle. Over time, the allele will spread throughout the population. Some alleles will quickly become fixed in this way, meaning that every individual of the population will carry the allele, while detrimental mutations may be swiftly eliminated if derived from a dominant allele from the gene pool. The gene pool is the sum of all the alleles in a population.

3. Sahar S. Hanania, Dchia S. Hassawi, and Nidal M. Irshaid, "Allele Frequency and Molecular Genotypes of ABO Blood Group System in a Jordanian Population," *Journal of Medical Sciences* 7 (2007): 51-58, doi:10.3923/jms.2007.51.58.

Sometimes, allele frequencies within a population change randomly with no advantage to the population over existing allele frequencies. This phenomenon is called genetic drift. Natural selection and genetic drift usually occur simultaneously in populations and are not isolated events. It is hard to determine which process dominates because it is often nearly impossible to determine the cause of change in allele frequencies at each occurrence. An event that initiates an allele frequency change in an isolated part of the population, which is not typical of the original population, is called the founder effect. Natural selection, random drift, and founder effects can lead to significant changes in the genome of a population.

Hardy–Weinberg Principle of Equilibrium

In the early twentieth century, English mathematician Godfrey Hardy and German physician Wilhelm Weinberg stated the principle of equilibrium to describe the genetic makeup of a population. The theory, which later became known as the Hardy–Weinberg principle of equilibrium, states that a population's allele and **genotype frequencies** are inherently stable—unless some kind of evolutionary force is acting upon the population, neither the allele nor the genotypic frequencies would change. The Hardy–Weinberg principle assumes conditions with no mutations, migration, emigration, or selective pressure for or against genotype, plus an infinite population; while no population can satisfy those conditions, the principle offers a useful model against which to compare real population changes.

Working under this theory, population geneticists represent different alleles as different variables in their mathematical models. The variable p , for example, typically represents the frequency of the dominant allele, say Y for the trait of yellow in Mendel's peas. The variable q represents the frequency of the recessive allele, in this case y , that confers the color green. If these are the only two possible alleles for a given locus in the population, $p + q = 1$. In other words, all the p alleles and all the q alleles make up all of the alleles for that locus that are found in the population.

But what ultimately interests most biologists is not the frequencies of different alleles, but the frequencies of the resulting genotypes, known as the population's **genetic structure**, from which scientists can surmise the distribution of phenotypes. If the phenotype is observed, only the genotype of the homozygous recessive alleles can be known; the calculations provide an estimate of the remaining genotypes. Since each individual carries two alleles per gene, if the allele frequencies (p and q) are known, predicting the frequencies of these genotypes is a simple mathematical calculation to determine the probability of getting these genotypes if two alleles are drawn at random from the gene pool. So in the above scenario, an individual pea plant could be pp (YY), and thus produce yellow peas; pq (Yy), also yellow; or qq (yy), and thus producing green peas (Figure 19.2). In other words, the frequency of pp individuals is simply p^2 ; the frequency of pq individuals is $2pq$; and the frequency of qq individuals is q^2 . And, again, if p and q are the only two possible alleles for a given trait in the population, these genotypes frequencies will sum to one: $p^2 + 2pq + q^2 = 1$.

visual CONNECTION

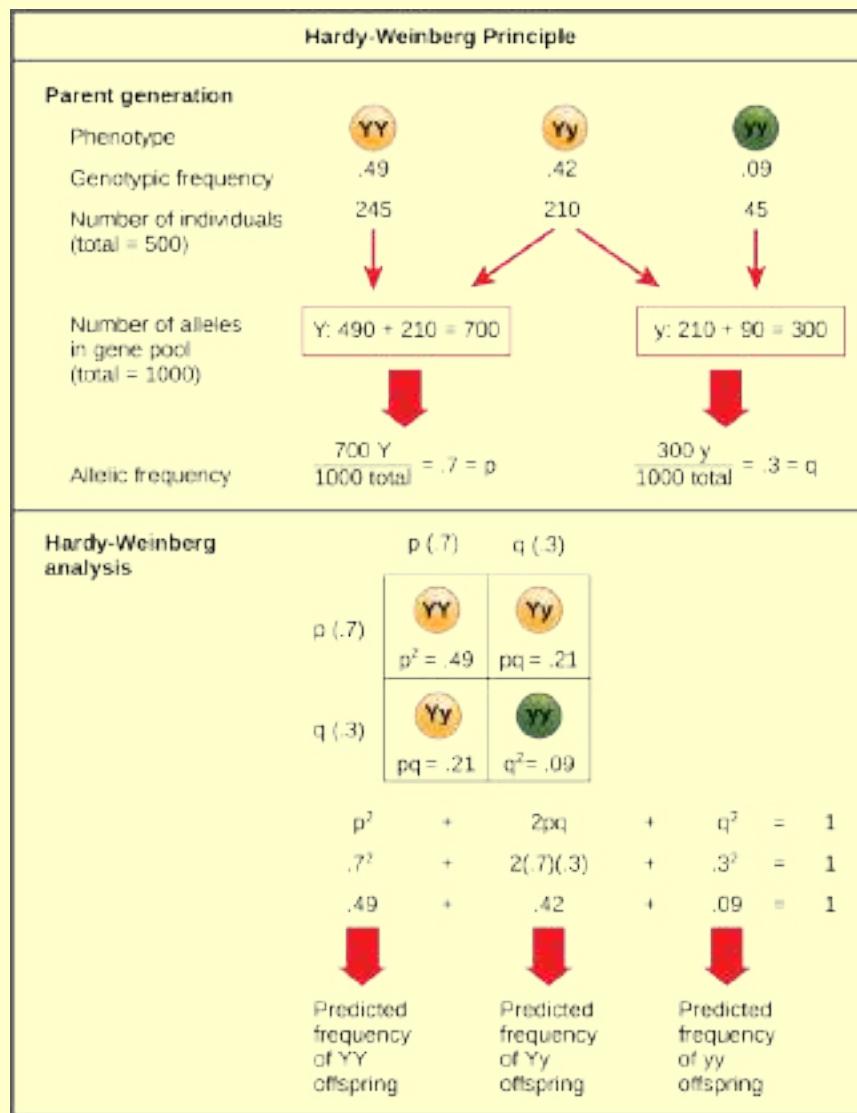

Figure 19.2 When populations are in the Hardy-Weinberg equilibrium, the allelic frequency is stable from generation to generation and the distribution of alleles can be determined from the Hardy-Weinberg equation. If the allelic frequency measured in the field differs from the predicted value, scientists can make inferences about what evolutionary forces are at play.

In plants, violet flower color (V) is dominant over white (v). If $p = 0.8$ and $q = 0.2$ in a population of 500 plants, how many individuals would you expect to be homozygous dominant (VV), heterozygous (Vv), and homozygous recessive (vv)? How many plants would you expect to have violet flowers, and how many would have white flowers?

- homozygous dominant: 320 heterozygous: 160 homozygous recessive: 20 violet: 480 white: 20
- homozygous dominant: 320 heterozygous: 80 homozygous recessive: 20 violet: 400 white: 20
- homozygous dominant: 400 heterozygous: 0 homozygous recessive: 100 violet: 400 white: 100
- homozygous dominant: 480 heterozygous: 0 homozygous recessive: 20 violet: 480 white: 20

In theory, if a population is at equilibrium—that is, there are no evolutionary forces acting upon it—generation after generation would have the same gene pool and genetic structure, and these equations would all hold true all of the time.

Of course, even Hardy and Weinberg recognized that no natural population is immune to evolution. Populations in nature are constantly changing in genetic makeup due to drift, mutation, possibly migration, and selection. As a result, the only way to determine the exact distribution of phenotypes in a population is to go out and count them. But the Hardy–Weinberg principle gives scientists a mathematical baseline of a non-evolving population to which they can compare evolving populations and thereby infer what evolutionary forces might be at play. If the frequencies of alleles or genotypes deviate from the value expected from the Hardy–Weinberg equation, then the population is evolving.

Use this **online calculator** (<http://openstaxcollege.org/l/hardy-weinberg>) to determine the genetic structure of a population.

What would violate the conditions of Hardy-Weinberg equilibrium?

- a. random mating
- b. mutations
- c. large population
- d. no natural selection

Lab Investigation

AP[®] Biology Investigative Labs: Inquiry-Based Approach, Investigation 2: Mathematical Modeling: Hardy–Weinberg. In this lab investigation, you apply the Hardy–Weinberg equation and create a spreadsheet to study changes in allele frequencies in a population and to examine possible causes for these changes.

Think About It

Imagine you are trying to determine if a population of flowers is undergoing microevolution. You suspect there is selection pressure on the color of the flower because bees seem to cluster around red flowers more often than blue flowers. In a separate experiment, you discover that blue flower color is dominant to red flower color. In a field, you count 600 blue flowers and 200 red flowers. Based on the H–W equation, what are the expected allele frequencies for flower color?

Two years later, you revisit the same field and discover that out of 1,000 flowers, 650 are blue. Use the H–W equation to determine if the population of flowers is undergoing evolution.

19.2 | Population Genetics

In this section, you will explore the following questions:

- What are the different types of variation in a population?
- Why can only heritable variation be acted upon by natural selection?
- How can genetic drift, the bottleneck effect, and the founder effect influence allele frequencies in a population?
- How can gene flow, mutation, nonrandom mating, and environmental variance affect allele frequencies in a population?

Connection for AP® Courses

Take a look at your classmates. Individuals of a population often display different phenotypes, or express different alleles of a particular gene. These differences are called **polymorphisms**. The distribution of phenotypes among individuals, known as **population variation**, is influenced by several factors, including the population's genetic structure and the environment (**Figure 19.3**). Understanding the sources of phenotypic variation is important for determining how a population will evolve in response to different evolutionary pressures. Only those variations that are encoded in an individual's genes can be passed to its offspring and be a target of natural selection.

Figure 19.3 The distribution of phenotypes in this litter of kittens illustrates population variation. (credit: Pieter Lanser)

As you learn in the chapter that discusses the evolution and origin of species, natural selection works by selecting for phenotypes—and the alleles that determine them—that confer beneficial traits or behaviors. Deleterious qualities are selected against. Genetic drift stems from the chance occurrence that some individuals have more offspring than others and, thus, will pass on more of their genes to the next generation. Small and isolated populations are more susceptible to genetic drift. Natural events, such as wildfires or hurricanes, can magnify genetic drift when a large portion of the population is killed. Because a fire does not distinguish between the genotypes of various organisms, no particular genotype survives the fire better than another. Therefore, the genetic structure of the surviving population may be very different from the genetic structure of the original population. This is called the bottleneck effect. Another scenario in which populations might experience a strong influence of genetic drift occurs when some portion of the population leaves to start a new population in a new location or gets separated by a physical barrier of some kind. In this situation, those individuals are unlikely to be representative of the entire population, a phenomenon called the founder effect. Both the bottleneck effect and the founder effect reduce genetic variation within a population—and genetic variation is the basis for natural selection. When individuals leave or join a population, they carry their alleles with them, resulting in changes in the population's allele frequencies. Allele frequencies also can change due to mutation in DNA and when individuals do not randomly mate with others; when an individual selects a mate based on phenotype, the genotype is also selected. In summary, any of these conditions can result in deviations from the Hardy–Weinberg equilibrium—and lead to the microevolution of a population.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent

foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Big Idea 1	The process of evolution drives the diversity and unity of life.
Enduring Understanding 1.A	Change in the genetic makeup of a population over time is evolution.
Essential Knowledge	1.A.1 Natural selection is a major mechanism of evolution.

Essential Knowledge	1.A.3 Evolutionary change is also driven by random processes.
Science Practice	6.4 The student can make claims and predictions about natural phenomena based on scientific theories and models.
Learning Objective	1.8 The student is able to make predictions about the effects of genetic drift, migration, and artificial selection on the genetic makeup of a population.
Essential Knowledge	1.A.3 Evolutionary change is also driven by random processes.
Science Practice	1.4 The student can use representatives and models to analyze situations or solve problems qualitatively and quantitatively.
Science Practice	2.1 The student can justify the selection of a mathematical routine to solve problems.
Learning Objective	1.6 The student is able to use data from mathematical models based on the Hardy–Weinberg equilibrium to analyze genetic drift and the effects of selection in the evolution of specific populations.
Essential Knowledge	1.A.3 Evolutionary change is also driven by random processes.
Science Practice	2.1 The student can justify the selection of a mathematical routine to solve problems.
Learning Objective	1.7 The student is able to justify data from mathematical models based on the Hardy–Weinberg equilibrium to analyze genetic drift and the effects of selection in the evolution of specific populations.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 1.1][APLO 1.3][APLO 1.4][APLO 1.8][APLO 1.23][APLO 1.24][APLO 1.25][APLO 1.6][APLO 1.7][APLO 1.22]

Genetic Variance

Natural selection and some of the other evolutionary forces can only act on heritable traits, namely an organism's genetic code. Because alleles are passed from parent to offspring, those that confer beneficial traits or behaviors may be selected for, while deleterious alleles may be selected against. Acquired traits, for the most part, are not heritable. For example, if an athlete works out in the gym every day, building up muscle strength, the athlete's offspring will not necessarily grow up to be a body builder. If there is a genetic basis for the ability to run fast, on the other hand, this may be passed to a child.

Before Darwinian evolution became the prevailing theory of the field, French naturalist Jean-Baptiste Lamarck theorized that acquired traits could, in fact, be inherited; while this hypothesis has largely been unsupported, scientists have recently begun to realize that Lamarck was not completely wrong. Visit this [site \(<http://openstaxcollege.org/l/epigenetic>\)](http://openstaxcollege.org/l/epigenetic) to learn more.

Explain naturalist Jean-Baptiste Lamarck's theory on heritability.

- a. Lamarck theorized that individuals more fit to their environment would be more likely to survive, reproduce, and pass on their genes.
- b. Lamarck theorized that traits that parents acquired in their lifetime could be inherited by offspring in an attempt to improve.
- c. Lamarck theorized that traits in offspring were a blend of traits from the two parents.
- d. Lamarck theorized that inbreeding would lead to higher proportions of homozygous recessive genotypes, potentially conferring recessive diseases onto offspring.

Heritability is the fraction of phenotype variation that can be attributed to genetic differences, or genetic variance, among individuals in a population. The greater the heredity of a population's phenotypic variation, the more susceptible it is to the evolutionary forces that act on heritable variation.

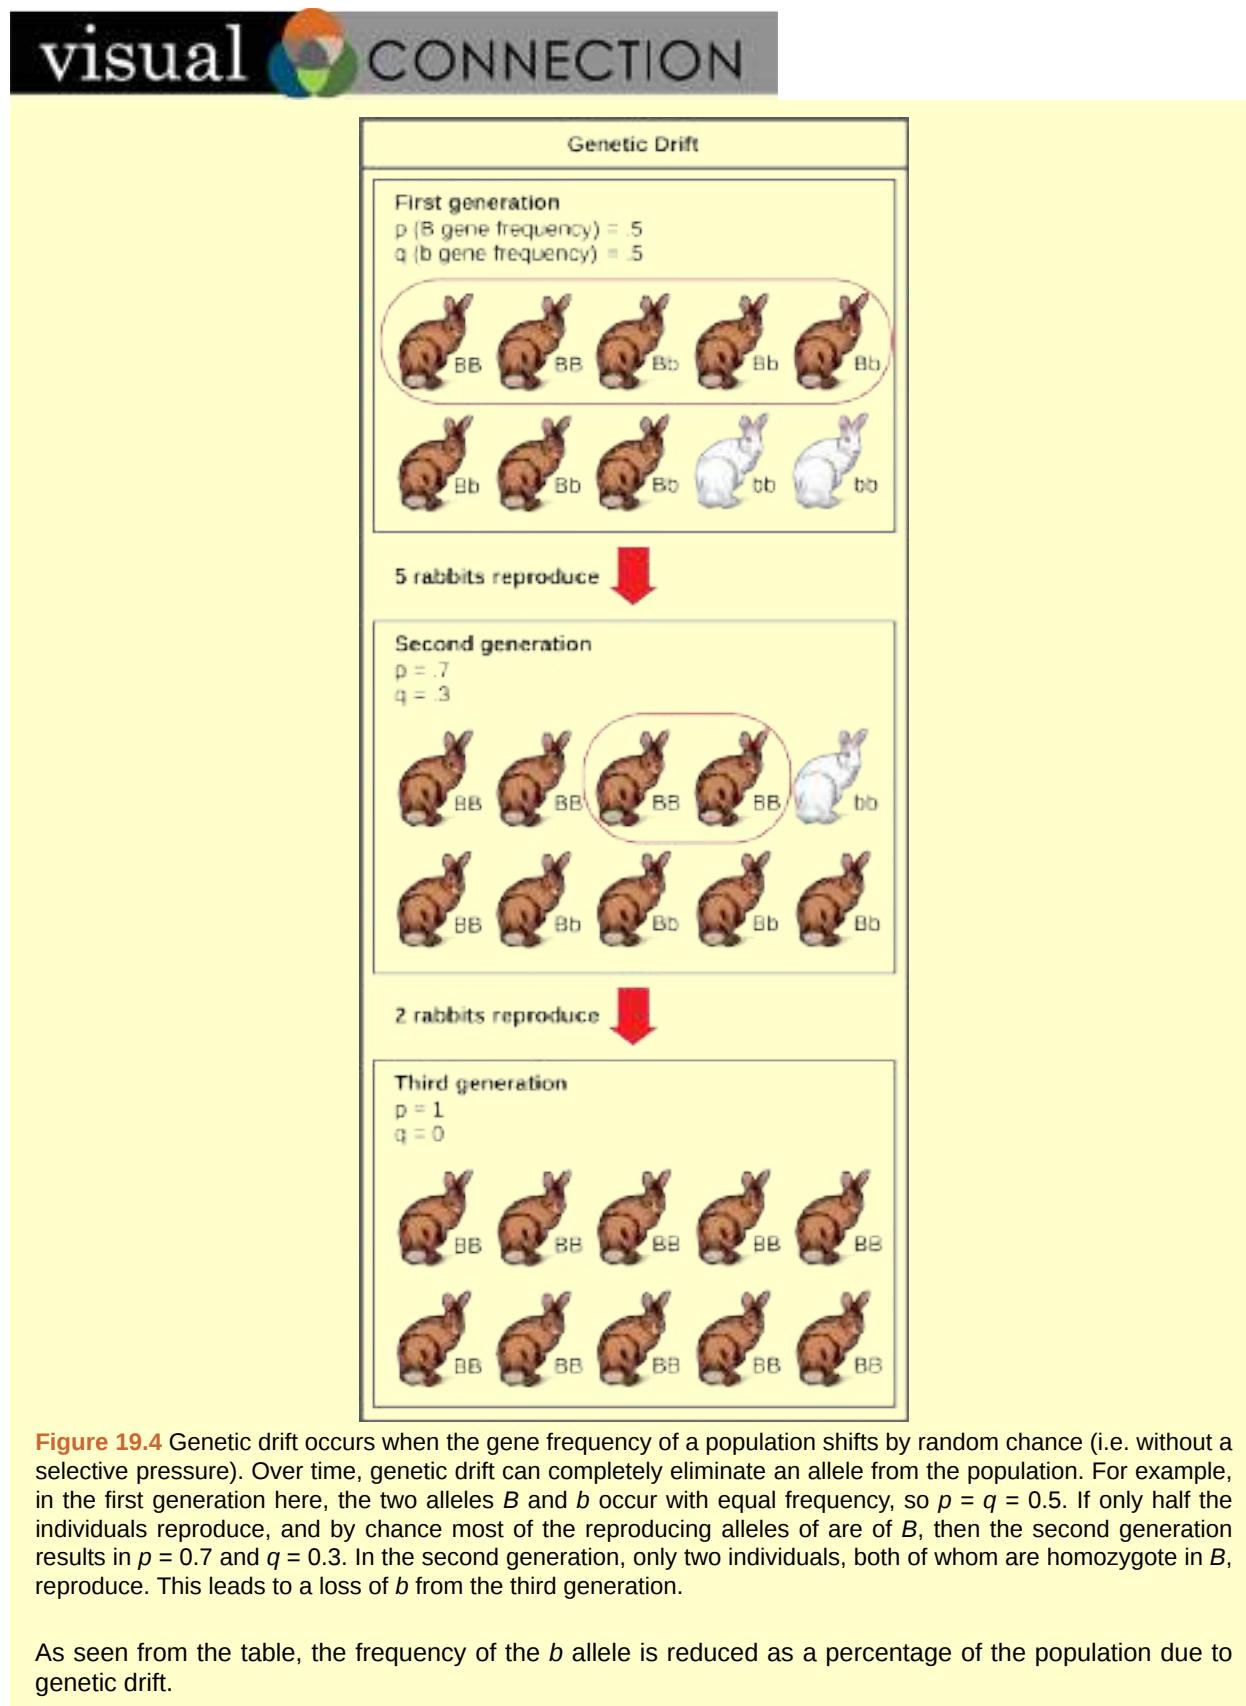

The diversity of alleles and genotypes within a population is called **genetic variance**. When scientists are involved in the breeding of a species, such as with animals in zoos and nature preserves, they try to increase a population's genetic variance to preserve as much of the phenotypic diversity as they can. This also helps reduce the risks associated with **inbreeding**, the mating of closely related individuals, which can have the undesirable effect of bringing together deleterious recessive mutations that can cause abnormalities and susceptibility to disease. For example, a disease that is caused by a rare, recessive allele might exist in a population, but it will only manifest itself when an individual carries two copies of the allele. Because the allele is rare in a normal, healthy population with unrestricted habitat, the chance that two carriers will mate is low, and even then, only 25 percent of their offspring will inherit the disease allele from both parents. While it is likely to happen at some point, it will not happen frequently enough for natural selection to be able to swiftly eliminate the allele from the population, and as a result, the allele will be maintained at low levels in the gene pool. However, if a family of carriers begins to interbreed with each other, this will dramatically increase the likelihood of two carriers mating and eventually producing diseased offspring, a phenomenon known as **inbreeding depression**.

Changes in allele frequencies that are identified in a population can shed light on how it is evolving. In addition to natural selection, there are other evolutionary forces that could be in play: genetic drift, gene flow, mutation, nonrandom mating, and environmental variances.

Genetic Drift

The theory of natural selection stems from the observation that some individuals in a population are more likely to survive longer and have more offspring than others; thus, they will pass on more of their genes to the next generation. A big, powerful male gorilla, for example, is much more likely than a smaller, weaker one to become the population's silverback, the pack's leader who mates far more than the other males of the group. The pack leader will father more offspring, who share half of his genes, and are likely to also grow bigger and stronger like their father. Over time, the genes for bigger size will increase in frequency in the population, and the population will, as a result, grow larger on average. That is, this would occur if this particular **selection pressure**, or driving selective force, were the only one acting on the population. In other examples, better camouflage or a stronger resistance to drought might pose a selection pressure.

Another way a population's allele and genotype frequencies can change is genetic drift ([Figure 19.4](#)), which is simply the effect of chance. By chance, some individuals will have more offspring than others—not due to an advantage conferred by some genetically-encoded trait, but just because one male happened to be in the right place at the right time (when the receptive female walked by) or because the other one happened to be in the wrong place at the wrong time (when a fox was hunting).

Generation	Individuals with genotype <i>BB</i>	Individuals with genotype <i>Bb</i>	Individuals with genotype <i>bb</i>
1	22	53	25
2	108	118	25
3	633	0	0

Table 19.1 Genotypic frequencies of rabbit populations undergoing genetic drift

Explain why small populations are more vulnerable to the forces of genetic drift than large populations.

- a. The fewer individuals in a population, the more room there is for new individuals to migrate into it.
- b. The more individuals in a population, the more alleles are present in its gene pool.
- c. The fewer individuals in a population, the more likely it is to go extinct.
- d. The more individuals in a population, the larger and more stable is its gene pool.

Small populations are more susceptible to the forces of genetic drift. Large populations, on the other hand, are buffered against the effects of chance. If one individual of a population of 10 individuals happens to die at a young age before it leaves any offspring to the next generation, all of its genes—1/10 of the population’s gene pool—will be suddenly lost. In a population of 100, that’s only 1 percent of the overall gene pool; therefore, it is much less impactful on the population’s genetic structure.

Go to this [site](http://openstaxcollege.org/l/genetic_drift) (http://openstaxcollege.org/l/genetic_drift) to watch an animation of random sampling and genetic drift in action.

Describe an example of genetic drift.

- a. Immigration of new individuals can cause genetic drift. For example, if several white rabbits migrate into a population of mostly brown rabbits, the allele for white fur will increase within the population.
- b. Introduction of new alleles through mutation can cause genetic drift. For example, if there are two alleles for fur color in a rabbit population, and a mutation in one of them produces a third allele, the gene pool changes to incorporate the new allele.
- c. Chance events such as a natural disaster can cause genetic drift. For example, if the only white rabbits in a population get killed by a storm, the allele for white fur will diminish or disappear in the population.
- d. Differential survival and reproduction can cause genetic drift. For example, if all the white rabbits in a population get eaten by wolves because their white fur stands out and is more visible, the proportion of the allele for white fur in the population will decrease.

Genetic drift can also be magnified by natural events, such as a natural disaster that kills—at random—a large portion of the population. Known as the bottleneck effect, it results in a large portion of the genome suddenly being wiped out (Figure 19.5). In one fell swoop, the genetic structure of the survivors becomes the genetic structure of the entire population, which may be very different from the pre-disaster population.

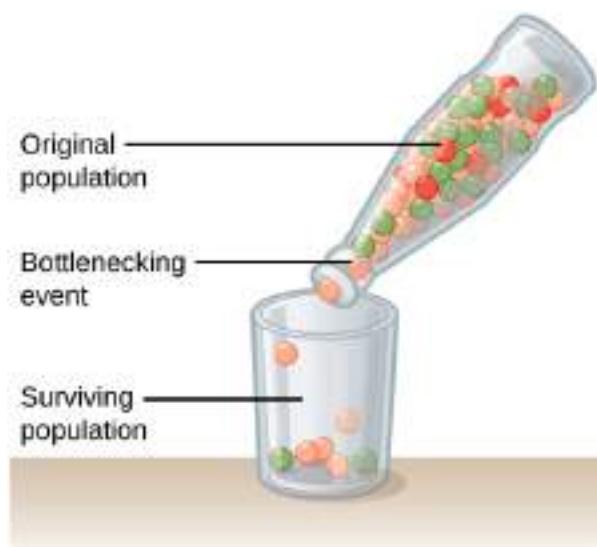

Figure 19.5 A chance event or catastrophe can reduce the genetic variability within a population.

Another scenario in which populations might experience a strong influence of genetic drift is if some portion of the population leaves to start a new population in a new location or if a population gets divided by a physical barrier of some kind. In this situation, those individuals are unlikely to be representative of the entire population, which results in the founder effect. The founder effect occurs when the genetic structure changes to match that of the new population's founding fathers and mothers. The founder effect is believed to have been a key factor in the genetic history of the Afrikaner population of Dutch settlers in South Africa, as evidenced by mutations that are common in Afrikaners but rare in most other populations. This is likely due to the fact that a higher-than-normal proportion of the founding colonists carried these mutations. As a result, the population expresses unusually high incidences of Huntington's disease (HD) and Fanconi anemia (FA), a genetic disorder known to cause blood marrow and congenital abnormalities.

Watch this short **video** (http://openstaxcollege.org/l/founder_bottle) to learn more about the founder and bottleneck effects.

Compare and contrast the bottleneck and founder effects.

- Both the bottleneck and founder effect are examples of gene flow. However, the bottleneck effect occurs after a cataclysmic event, whereas the founder effect occurs when mutations introduce new alleles into a population.
- Both the bottleneck and founder effect are examples of genetic drift. However, the bottleneck effect is a process in which a large portion of a genome is wiped out, whereas the founder effect occurs when members of a larger population migrate to establish their own population.
- Both the bottleneck and founder effect change the genetic structure of a population. However, the bottleneck effect reduces or eliminates alleles within a population, whereas the founder effect introduces or increases alleles.
- Both the bottleneck and founder effect change the genetic structure of a population. However, the bottleneck effect occurs when inbreeding depression kills off part of a population, whereas the founder effect relies on nonrandom mating.

scientific method CONNECTION

Testing the Bottleneck Effect

Question: How do natural disasters affect the genetic structure of a population?

Background: When much of a population is suddenly wiped out by an earthquake or hurricane, the individuals that survive the event are usually a random sampling of the original group. As a result, the genetic makeup of the population can change dramatically. This phenomenon is known as the bottleneck effect.

Hypothesis: Repeated natural disasters will yield different population genetic structures; therefore, each time this experiment is run, the results will vary.

Test the hypothesis: Count out the original population using different colored beads. For example, red, blue, and yellow beads might represent red, blue, and yellow individuals. After recording the number of each individual in the original population, place them all in a bottle with a narrow neck that will only allow a few beads out at a time. Then, pour 1/3 of the bottle's contents into a bowl. This represents the surviving individuals after a natural disaster kills a majority of the population. Count the number of the different colored beads in the bowl, and record it. Then, place all of the beads back in the bottle and repeat the experiment four more times.

Analyze the data: Compare the five populations that resulted from the experiment. Do the populations all contain the same number of different colored beads, or do they vary? Remember, these populations all came from the same exact parent population.

Form a conclusion: Most likely, the five resulting populations will differ quite dramatically. This is because natural disasters are not selective—they kill and spare individuals at random. Now think about how this might affect a real population. What happens when a hurricane hits the Mississippi Gulf Coast? How do the seabirds that live on the beach fare?

Gene Flow

Another important evolutionary force is **gene flow**: the flow of alleles in and out of a population due to the migration of individuals or gametes (Figure 19.6). While some populations are fairly stable, others experience more flux. Many plants, for example, send their pollen far and wide, by wind or by bird, to pollinate other populations of the same species some distance away. Even a population that may initially appear to be stable, such as a pride of lions, can experience its fair share of immigration and emigration as developing males leave their mothers to seek out a new pride with genetically unrelated females. This variable flow of individuals in and out of the group not only changes the gene structure of the population, but it can also introduce new genetic variation to populations in different geological locations and habitats.

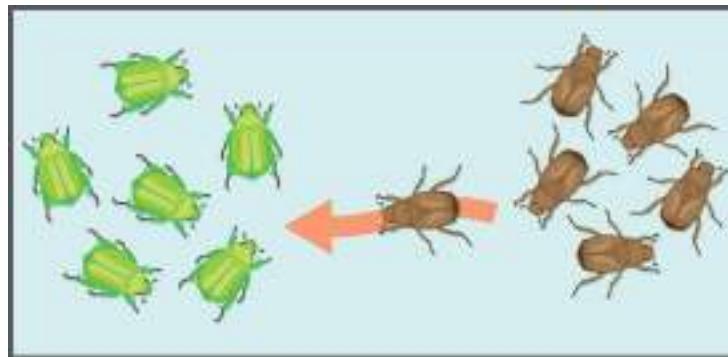

Figure 19.6 Gene flow can occur when an individual travels from one geographic location to another.

Mutation

Mutations are changes to an organism's DNA and are an important driver of diversity in populations. Species evolve because of the accumulation of mutations that occur over time. The appearance of new mutations is the most common way to introduce novel genotypic and phenotypic variance. Some mutations are unfavorable or harmful and are quickly

eliminated from the population by natural selection. Others are beneficial and will spread through the population. Whether or not a mutation is beneficial or harmful is determined by whether it helps an organism survive to sexual maturity and reproduce. Some mutations do not do anything and can linger, unaffected by natural selection, in the genome. Some can have a dramatic effect on a gene and the resulting phenotype.

Nonrandom Mating

If individuals nonrandomly mate with their peers, the result can be a changing population. There are many reasons **nonrandom mating** occurs. One reason is simple mate choice; for example, female peahens may prefer peacocks with bigger, brighter tails. Traits that lead to more matings for an individual become selected for by natural selection. One common form of mate choice, called **assortative mating**, is an individual's preference to mate with partners who are phenotypically similar to themselves.

Another cause of nonrandom mating is physical location. This is especially true in large populations spread over large geographic distances where not all individuals will have equal access to one another. Some might be miles apart through woods or over rough terrain, while others might live immediately nearby.

Environmental Variance

Genes are not the only players involved in determining population variation. Phenotypes are also influenced by other factors, such as the environment (Figure 19.7). For example, sun exposure is an environmental factor, as a person who spends more time in the sun will likely have darker skin than a person who spends most of their time indoors (assuming both people had similarly-colored skin to start with). Some major characteristics, such as sex, are determined by the environment for some species. For example, some turtles and other reptiles have temperature-dependent sex determination (TSD). TSD means that individuals develop into males if their eggs are incubated within a certain temperature range, or females at a different temperature range.

Figure 19.7 The sex of the American alligator (*Alligator mississippiensis*) is determined by the temperature at which the eggs are incubated. Eggs incubated at 30°C produce females, and eggs incubated at 33°C produce males. (credit: Steve Hillebrand, USFWS)

Geographic separation between populations can lead to differences in the phenotypic variation between those populations. Such **geographical variation** is seen between most populations and can be significant. One type of geographic variation, called a **cline**, can be seen as populations of a given species vary gradually across an ecological gradient. Species of warm-blooded animals, for example, tend to have larger bodies in the cooler climates closer to the earth's poles, allowing them to better conserve heat. This is considered a latitudinal cline. Alternatively, flowering plants tend to bloom at different times depending on where they are along the slope of a mountain, known as an altitudinal cline.

If there is gene flow between the populations, the individuals will likely show gradual differences in phenotype along the cline. Restricted gene flow, on the other hand, can lead to abrupt differences, even speciation.

Lab Investigation

AP® Biology Investigative Labs: Inquiry-Based Approach, Investigation 1: Artificial Selection. Using Wisconsin Fast Plants, you explore evolution by conducting an artificial selection investigation to increase or decrease genetic variation in a population and then determine if extreme selection can change the expression of a quantitative trait.

Think About It

- Do you think genetic drift would happen more quickly on an island or on the mainland? Provide reasoning for your answer.
- Consider the population of red and blue flowers you analyzed in Section 1 to determine if they were undergoing microevolution. Recall that you counted 600 blue flowers and 200 red flowers.
- Imagine that you return four years after your initial visit, and the flowers at the site have been split into two different populations by a newly formed river, which isolates the two populations. In the population 1, you counted 125 blue flowers and 10 red flowers. In the population 2, you counted 450 blue flowers and 300 red flowers. Did genetic drift or natural selection likely cause these change in allele frequencies in population 1? What about population 2? Explain how you know for each population.

19.3 | Adaptive Evolution

In this section, you will explore the following questions:

- What are different ways in which natural selection can shape populations?
- How can these different forces lead to different outcomes in terms of population variation?

Connections for AP® Courses

As we have learned, natural selection acts on the level of the individual, selecting those with a higher overall **fitness** (reproductive success) compared to the rest of the population. In other words, natural selection favors the most adaptive variation for a given environment. If the fit phenotypes are evolving in a stable environment, natural selection results in **stabilizing selection**, resulting in an overall decrease in the population's variation. However, if environmental conditions change, **directional selection** shifts a population's variance toward a new and more favorable phenotype. **Diversifying selection** results in increased variance by selecting for two or more distinct phenotypes.

Sexual selection results when one sex has more reproductive success than the other; as a result, males and females experience different selective pressures, which often lead to distinct phenotypic differences, or **sexual dimorphisms**, between the two. For example, male birds often exhibit more colorful plumage than female birds of the same species.

What is most important to recognize is that there is no perfect organism. Natural selection acts on existing variations in the population; it does not create anything from scratch. Although natural selection selects the fittest individuals, other forces of evolution, including genetic drift and gene flow, often introduce deleterious alleles to the population's gene pool. Evolution has no purpose; it is simply the sum of various forces that influence the genetic and phenotypic variation of a population.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Big Idea 1

The process of evolution drives the diversity and unity of life.

Enduring Understanding 1.A	Change in the genetic makeup of a population over time is evolution.
Essential Knowledge	1.A.1 Natural selection is a major mechanism of evolution.
Science Practice	2.2 The student can apply mathematical routines to quantities that describe natural phenomena.
Science Practice	5.3 The student can evaluate the evidence provided by data sets in relation to a particular scientific question.
Learning Objective	1.2 The student is able to evaluate evidence provided by data to qualitatively and quantitatively investigate the role of natural selection in evolution.
Essential Knowledge	1.A.2 Natural selection acts on phenotypic variations in populations.
Science Practice	7.1 The student can connect phenomena and models across spatial and temporal scales.
Learning Objective	1.5 The student is able to connect evolutionary changes in a population over time to a change in the environment.

Natural selection only acts on the population's heritable traits: selecting for beneficial alleles and thus increasing their frequency in the population, while selecting against deleterious alleles and thereby decreasing their frequency—a process known as **adaptive evolution**. Natural selection does not act on individual alleles, however, but on entire organisms. An individual may carry a very beneficial genotype with a resulting phenotype that, for example, increases the ability to reproduce (fecundity), but if that same individual also carries an allele that results in a fatal childhood disease, that fecundity phenotype will not be passed on to the next generation because the individual will not live to reach reproductive age. Natural selection acts at the level of the individual; it selects for individuals with greater contributions to the gene pool of the next generation, known as an organism's **evolutionary (Darwinian) fitness**.

Fitness is often quantifiable and is measured by scientists in the field. However, it is not the absolute fitness of an individual that counts, but rather how it compares to the other organisms in the population. This concept, called **relative fitness**, allows researchers to determine which individuals are contributing additional offspring to the next generation, and thus, how the population might evolve.

There are several ways selection can affect population variation: stabilizing selection, directional selection, diversifying selection, frequency-dependent selection, and sexual selection. As natural selection influences the allele frequencies in a population, individuals can either become more or less genetically similar and the phenotypes displayed can become more similar or more disparate.

Stabilizing Selection

If natural selection favors an average phenotype, selecting against extreme variation, the population will undergo stabilizing selection ([Figure 19.9](#)). In a population of mice that live in the woods, for example, natural selection is likely to favor individuals that best blend in with the forest floor and are less likely to be spotted by predators. Assuming the ground is a fairly consistent shade of brown, those mice whose fur is most closely matched to that color will be most likely to survive and reproduce, passing on their genes for their brown coat. Mice that carry alleles that make them a bit lighter or a bit darker will stand out against the ground and be more likely to fall victim to predation. As a result of this selection, the population's genetic variance will decrease.

Directional Selection

When the environment changes, populations will often undergo directional selection ([Figure 19.9](#)), which selects for phenotypes at one end of the spectrum of existing variation. A classic example of this type of selection is the evolution of the peppered moth in eighteenth- and nineteenth-century England. Prior to the Industrial Revolution, the moths were predominately light in color, which allowed them to blend in with the light-colored trees and lichens in their environment. But as soot began spewing from factories, the trees became darkened, and the light-colored moths became easier for predatory birds to spot. Over time, the frequency of the melanic form of the moth increased because they had a higher survival rate in habitats affected by air pollution because their darker coloration blended with the sooty trees.

Scientists can observe directional selection. Suppose populations of rabbits that eat flowers are introduced into an environment with flowering plants. Once the flowers are eaten, the plants cannot reproduce. Over time, the height of the flowers will shift higher so that the rabbits cannot reach them ???.

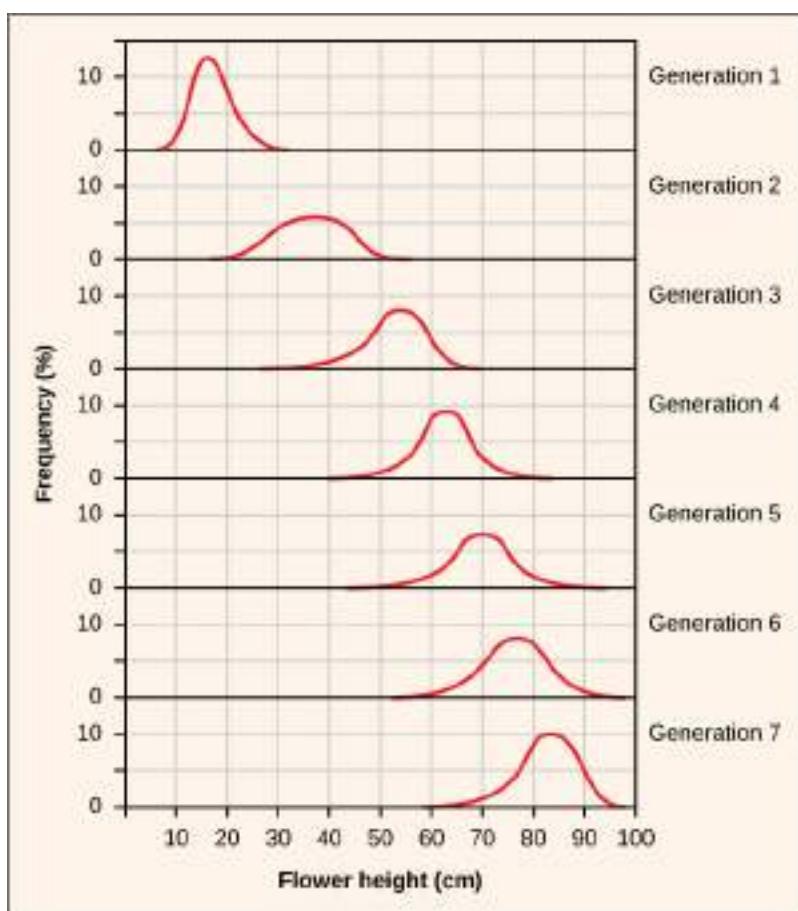

Figure 19.8 The introduction of small herbivores that eat flowers often results in directional selection for increased flower height.

In science, sometimes things are believed to be true, and then new information comes to light that changes our understanding. The story of the peppered moth is an example: the facts behind the selection toward darker moths have recently been called into question. Read this [article](http://openstaxcollege.org/l/peppered_moths) (http://openstaxcollege.org/l/peppered_moths) to learn more.

What is fitness the measure of?

- the frequency of beneficial alleles
- the effect of chance on a population's gene pool
- successful reproduction
- the abnormalities in a population

Diversifying Selection

Sometimes two or more distinct phenotypes can each have their advantages and be selected for by natural selection, while the intermediate phenotypes are, on average, less fit. Known as diversifying selection (Figure 19.9), this is seen in many populations of animals that have multiple male forms. Large, dominant alpha males obtain mates by brute force, while small males can sneak in for furtive copulations with the females in an alpha male's territory. In this case, both the alpha males and the "sneaking" males will be selected for, but medium-sized males, which can't overtake the alpha males and are too big to sneak copulations, are selected against. Diversifying selection can also occur when environmental changes favor individuals on either end of the phenotypic spectrum. Imagine a population of mice living at the beach where there is light-colored sand interspersed with patches of tall grass. In this scenario, light-colored mice that blend in with the sand would be favored, as well as dark-colored mice that can hide in the grass. Medium-colored mice, on the other hand, would not blend in with either the grass or the sand, and would thus be more likely to be eaten by predators. The result of this type of selection is increased genetic variance as the population becomes more diverse.

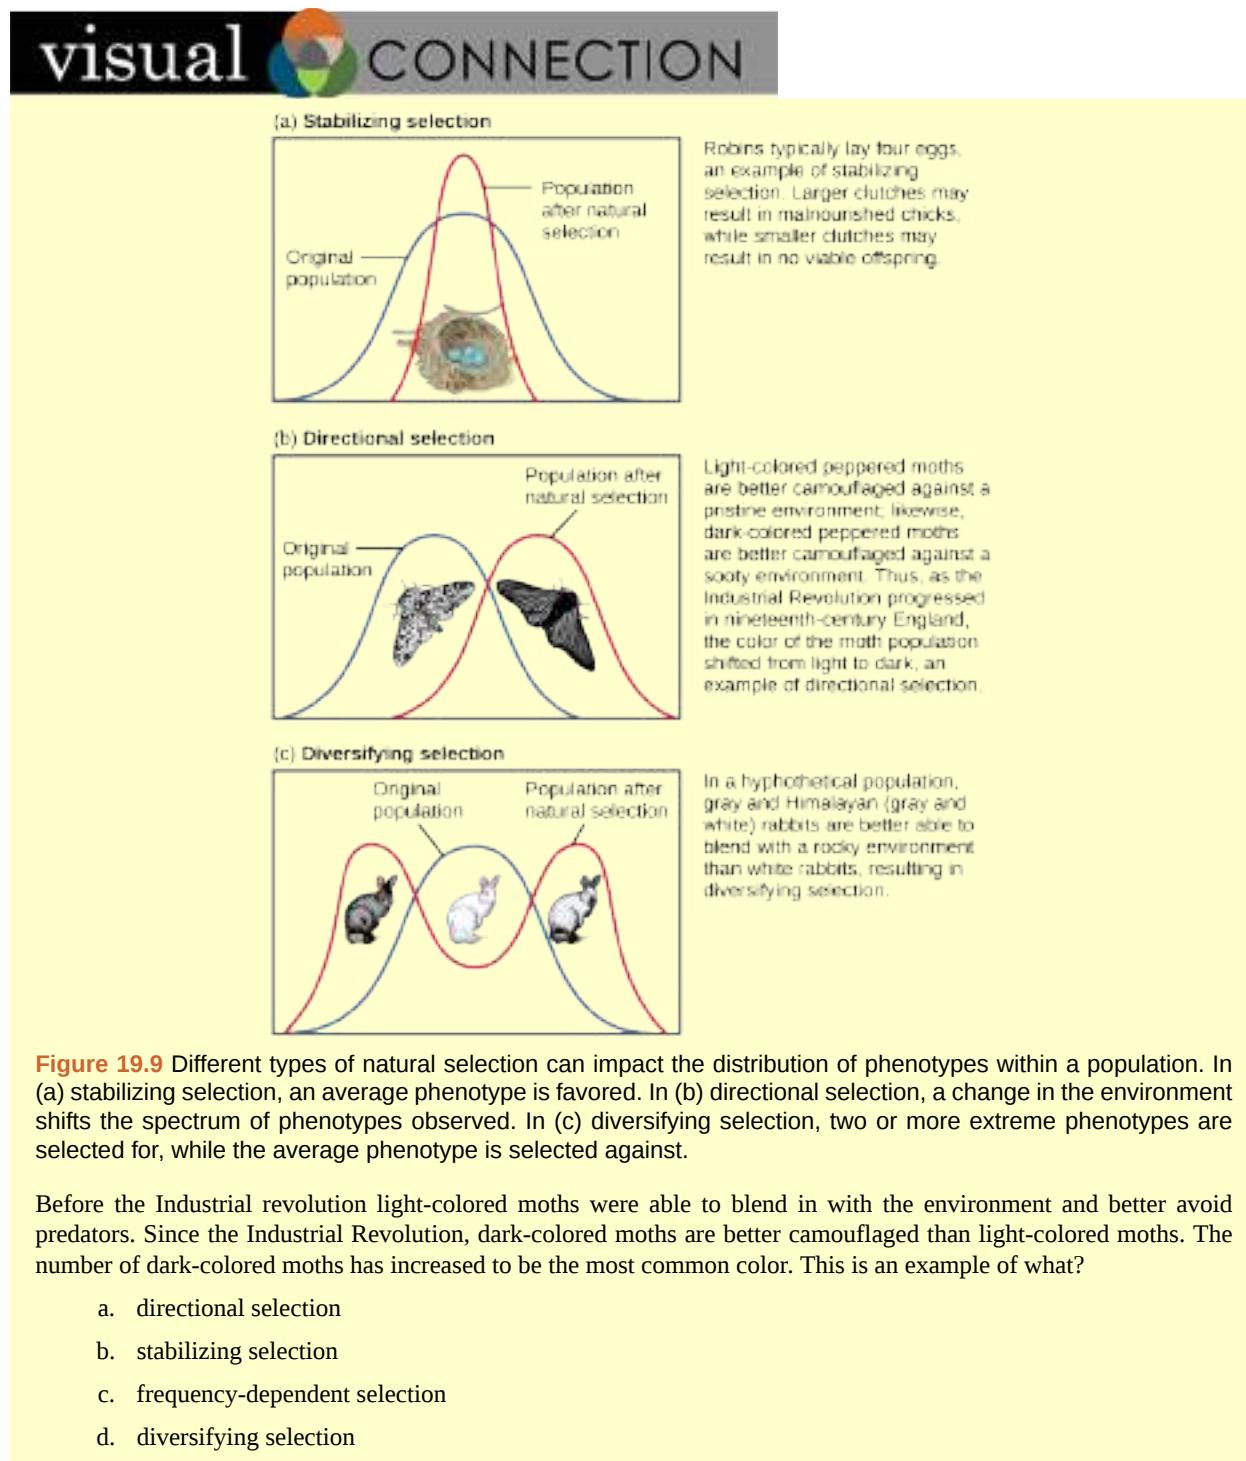

Figure 19.9 Different types of natural selection can impact the distribution of phenotypes within a population. In (a) stabilizing selection, an average phenotype is favored. In (b) directional selection, a change in the environment shifts the spectrum of phenotypes observed. In (c) diversifying selection, two or more extreme phenotypes are selected for, while the average phenotype is selected against.

Before the Industrial revolution light-colored moths were able to blend in with the environment and better avoid predators. Since the Industrial Revolution, dark-colored moths are better camouflaged than light-colored moths. The number of dark-colored moths has increased to be the most common color. This is an example of what?

- directional selection
- stabilizing selection
- frequency-dependent selection
- diversifying selection

Frequency-dependent Selection

Another type of selection, called **frequency-dependent selection**, favors phenotypes that are either common (positive frequency-dependent selection) or rare (negative frequency-dependent selection). An interesting example of this type of selection is seen in a unique group of lizards of the Pacific Northwest. Male common side-blotched lizards come in three throat-color patterns: orange, blue, and yellow. Each of these forms has a different reproductive strategy: orange males are the strongest and can fight other males for access to their females; blue males are medium-sized and form strong pair bonds with their mates; and yellow males (**Figure 19.10**) are the smallest, and look a bit like females, which allows them

to sneak copulations. Like a game of rock-paper-scissors, orange beats blue, blue beats yellow, and yellow beats orange in the competition for females. That is, the big, strong orange males can fight off the blue males to mate with the blue's pair-bonded females, the blue males are successful at guarding their mates against yellow sneaker males, and the yellow males can sneak copulations from the potential mates of the large, polygynous orange males.

Figure 19.10 A yellow-throated side-blotched lizard is smaller than either the blue-throated or orange-throated males and appears a bit like the females of the species, allowing it to sneak copulations. (credit: "tinyfroglet"/Flickr)

In this scenario, orange males will be favored by natural selection when the population is dominated by blue males, blue males will thrive when the population is mostly yellow males, and yellow males will be selected for when orange males are the most populous. As a result, populations of side-blotched lizards cycle in the distribution of these phenotypes—in one generation, orange might be predominant, and then yellow males will begin to rise in frequency. Once yellow males make up a majority of the population, blue males will be selected for. Finally, when blue males become common, orange males will once again be favored.

Negative frequency-dependent selection serves to increase the population's genetic variance by selecting for rare phenotypes, whereas positive frequency-dependent selection usually decreases genetic variance by selecting for common phenotypes.

Sexual Selection

Males and females of certain species are often quite different from one another in ways beyond the reproductive organs. Males are often larger, for example, and display many elaborate colors and adornments, like the peacock's tail, while females tend to be smaller and duller in decoration. Such differences are known as sexual dimorphisms (**Figure 19.11**), which arise from the fact that in many populations, particularly animal populations, there is more variance in the reproductive success of the males than there is of the females. That is, some males—often the bigger, stronger, or more decorated males—get the vast majority of the total matings, while others receive none. This can occur because the males are better at fighting off other males, or because females will choose to mate with the bigger or more decorated males. In either case, this variation in reproductive success generates a strong selection pressure among males to get those matings, resulting in the evolution of bigger body size and elaborate ornaments to get the females' attention. Females, on the other hand, tend to get a handful of selected matings; therefore, they are more likely to select more desirable males.

Sexual dimorphism varies widely among species, of course, and some species are even sex-role reversed. In such cases, females tend to have a greater variance in their reproductive success than males and are correspondingly selected for the bigger body size and elaborate traits usually characteristic of males.

Figure 19.11 Sexual dimorphism is observed in (a) peacocks and peahens, (b) *Argiope appensa* spiders (the female spider is the large one), and in (c) wood ducks. (credit “spiders”: modification of work by “Sanba38”/Wikimedia Commons; credit “duck”: modification of work by Kevin Cole)

The selection pressures on males and females to obtain matings is known as sexual selection; it can result in the development of secondary sexual characteristics that do not benefit the individual’s likelihood of survival but help to maximize its reproductive success. Sexual selection can be so strong that it selects for traits that are actually detrimental to the individual’s survival. Think, once again, about the peacock’s tail. While it is beautiful and the male with the largest, most colorful tail is more likely to win the female, it is not the most practical appendage. In addition to being more visible to predators, it makes the males slower in their attempted escapes. There is some evidence that this risk, in fact, is why females like the big tails in the first place. The speculation is that large tails carry risk, and only the best males survive that risk: the bigger the tail, the more fit the male. This idea is known as the **handicap principle**.

The **good genes hypothesis** states that males develop these impressive ornaments to show off their efficient metabolism or their ability to fight disease. Females then choose males with the most impressive traits because it signals their genetic superiority, which they will then pass on to their offspring. Though it might be argued that females should not be picky because it will likely reduce their number of offspring, if better males father more fit offspring, it may be beneficial. Fewer, healthier offspring may increase the chances of survival more than many, weaker offspring.

In 1915, biologist Ronald Fisher proposed another model of sexual selection: the **Fisherian runaway model** (http://openstaxcollege.org/l/sexual_select) , which suggests that selection of certain traits is a result of sexual preference.

Explain the handicap principle.

- The peacock's tail is an example of the handicap principle. Having a healthy, beautiful tail discourages predation, helping in survival. This means that those individuals are most likely to survive and produce offspring.
- The peacock's tail is an example of the handicap principle. It appears that the tail makes the males more visible to predators and less able to escape, making it a disadvantage to the birds' survival. However, traits cannot evolve in a population if they serve as a handicap to the individuals that express that trait. Therefore, the tail must actually be an advantage.
- The peacock's tail is an example of the handicap principle. The tail makes the males more visible to predators and less able to escape, so the birds with the longest and most extravagant tails get eaten and do not reproduce. This causes the average tail length for males within the population to decrease over time due to natural selection.
- The peacock's tail is an example of the handicap principle. The tail, which makes the males more visible to predators and less able to escape, is clearly a disadvantage to the birds' survival. But because it is a disadvantage, only the most fit males should be able to survive with it. Thus, the tail serves as an honest signal of quality to the females of the population; therefore, the male will earn more matings and greater reproductive success.

In both the handicap principle and the good genes hypothesis, the trait is said to be an **honest signal** of the males' quality, thus giving females a way to find the fittest mates—males that will pass the best genes to their offspring.

No Perfect Organism

Natural selection is a driving force in evolution and can generate populations that are better adapted to survive and successfully reproduce in their environments. But natural selection cannot produce the perfect organism. Natural selection can only select on existing variation in the population; it does not create anything from scratch. Thus, it is limited by a population's existing genetic variance and whatever new alleles arise through mutation and gene flow.

Natural selection is also limited because it works at the level of individuals, not alleles, and some alleles are linked due to their physical proximity in the genome, making them more likely to be passed on together (linkage disequilibrium). Any given individual may carry some beneficial alleles and some unfavorable alleles. It is the net effect of these alleles, or the organism's fitness, upon which natural selection can act. As a result, good alleles can be lost if they are carried by individuals that also have several overwhelmingly bad alleles; likewise, bad alleles can be kept if they are carried by individuals that have enough good alleles to result in an overall fitness benefit.

Furthermore, natural selection can be constrained by the relationships between different polymorphisms. One morph may confer a higher fitness than another, but may not increase in frequency due to the fact that going from the less beneficial to the more beneficial trait would require going through a less beneficial phenotype. Think back to the mice that live at the beach. Some are light-colored and blend in with the sand, while others are dark and blend in with the patches of grass. The dark-colored mice may be, overall, more fit than the light-colored mice, and at first glance, one might expect the light-colored mice be selected for a darker coloration. But remember that the intermediate phenotype, a medium-colored coat, is very bad for the mice—they cannot blend in with either the sand or the grass and are more likely to be eaten by predators. As a result, the light-colored mice would not be selected for a dark coloration because those individuals that began moving in that direction (began being selected for a darker coat) would be less fit than those that stayed light.

Finally, it is important to understand that not all evolution is adaptive. While natural selection selects the fittest individuals and often results in a more fit population overall, other forces of evolution, including genetic drift and gene flow, often do the opposite: introducing deleterious alleles to the population's gene pool. Evolution has no purpose—it is not changing a population into a preconceived ideal. It is simply the sum of the various forces described in this chapter and how they influence the genetic and phenotypic variance of a population.

science practices CONNECTION for AP[®] Courses

Think About It

In recent years, factories have been cleaner, and less soot is released into the environment. What impact do you think this has had on the distribution of moth color in the population?

KEY TERMS

- adaptive evolution** increase in frequency of beneficial alleles and decrease in deleterious alleles due to selection
- allele frequency** (also, gene frequency) rate at which a specific allele appears within a population
- assortative mating** when individuals tend to mate with those who are phenotypically similar to themselves
- bottleneck effect** magnification of genetic drift as a result of natural events or catastrophes
- cline** gradual geographic variation across an ecological gradient
- directional selection** selection that favors phenotypes at one end of the spectrum of existing variation
- diversifying selection** selection that favors two or more distinct phenotypes
- evolutionary fitness** (also, Darwinian fitness) individual's ability to survive and reproduce
- fitness** measure of successful reproduction, the passing on alleles to the next generation
- founder effect** event that initiates an allele frequency change in part of the population, which is not typical of the original population
- frequency-dependent selection** selection that favors phenotypes that are either common (positive frequency-dependent selection) or rare (negative frequency-dependent selection)
- gene flow** flow of alleles in and out of a population due to the migration of individuals or gametes
- gene pool** all of the alleles carried by all of the individuals in the population
- genetic drift** effect of chance on a population's gene pool
- genetic structure** distribution of the different possible genotypes in a population
- genetic variance** diversity of alleles and genotypes in a population
- genotype frequency** the proportion of a specific genotype in a population relative to all other genotypes for those genes that are present in the population
- geographical variation** differences in the phenotypic variation between populations that are separated geographically
- good genes hypothesis** theory of sexual selection that argues individuals develop impressive ornaments to show off their efficient metabolism or ability to fight disease
- handicap principle** theory of sexual selection that argues only the fittest individuals can afford costly traits
- Hardy–Weinberg principle of equilibrium** a stable, non-evolving state of a population in which allelic frequencies are stable over time
- heritability** fraction of population variation that can be attributed to its genetic variance
- honest signal** trait that gives a truthful impression of an individual's fitness
- inbreeding** mating of closely related individuals
- inbreeding depression** increase in abnormalities and disease in inbreeding populations
- macroevolution** broader scale evolutionary changes seen over paleontological time
- microevolution** changes in a population's genetic structure
- modern synthesis** overarching evolutionary paradigm that took shape by the 1940s and is generally accepted today

nonrandom mating changes in a population's gene pool due to mate choice or other forces that cause individuals to mate with certain phenotypes more than others

polymorphisms variations in phenotype within individuals of a population

population genetics study of how selective forces change the allele frequencies in a population over time

population variation distribution of phenotypes in a population

relative fitness individual's ability to survive and reproduce relative to the rest of the population

selective pressure environmental factor that causes one phenotype to be better than another

sexual dimorphism phenotypic difference between the males and females of a population

stabilizing selection selection that favors average phenotypes

CHAPTER SUMMARY

19.1 Population Evolution

The modern synthesis of evolutionary theory grew out of the cohesion of Darwin's, Wallace's, and Mendel's thoughts on evolution and heredity, along with the more modern study of population genetics. It describes the evolution of populations and species, from small-scale changes among individuals to large-scale changes over paleontological time periods. To understand how organisms evolve, scientists can track populations' allele frequencies over time. If they differ from generation to generation, scientists can conclude that the population is not in Hardy–Weinberg equilibrium, and is thus evolving.

19.2 Population Genetics

Both genetic and environmental factors can cause phenotypic variation in a population. Different alleles can confer different phenotypes, and different environments can also cause individuals to look or act differently. Only those differences encoded in an individual's genes, however, can be passed to its offspring and, thus, be a target of natural selection. Natural selection works by selecting for alleles that confer beneficial traits or behaviors, while selecting against those for deleterious qualities. Genetic drift stems from the chance occurrence that some individuals in the germ line have more offspring than others. When individuals leave or join the population, allele frequencies can change as a result of gene flow. Mutations to an individual's DNA may introduce new variation into a population. Allele frequencies can also be altered when individuals do not randomly mate with others in the group.

19.3 Adaptive Evolution

Because natural selection acts to increase the frequency of beneficial alleles and traits while decreasing the frequency of deleterious qualities, it is adaptive evolution. Natural selection acts at the level of the individual, selecting for those that have a higher overall fitness compared to the rest of the population. If the fit phenotypes are those that are similar, natural selection will result in stabilizing selection, and an overall decrease in the population's variation. Directional selection works to shift a population's variance toward a new, fit phenotype, as environmental conditions change. In contrast, diversifying selection results in increased genetic variance by selecting for two or more distinct phenotypes.

Other types of selection include frequency-dependent selection, in which individuals with either common (positive frequency-dependent selection) or rare (negative frequency-dependent selection) are selected for. Finally, sexual selection results from the fact that one sex has more variance in the reproductive success than the other. As a result, males and females experience different selective pressures, which can often lead to the evolution of phenotypic differences, or sexual dimorphisms, between the two.

REVIEW QUESTIONS

1. What is the ultimate source of all variation in and among populations?

- a. genetic mutations that result in viable offspring
 b. natural selection
 c. diverse habitats
 d. factors in the environment that may affect development
- 2.** When male lions reach sexual maturity, they are thrown out of their group, or pride, and must live on their own or with other males until they can take over their own pride. This can alter the allele frequencies of the population through which of the following mechanisms?
- natural selection
 - gene flow
 - random mating
 - genetic drift
- 3.** Which of the following populations has violated the conditions of Hardy-Weinberg Equilibrium?
- an infinitely large population
 - a population in which the allele frequencies do not change over time
 - a population in which the Hardy-Weinberg equation is equal to 1
 - a population undergoing natural selection
- 4.** What is the difference between micro and macroevolution?
- Microevolution describes the evolution of small organisms, such as insects, while macroevolution describes the evolution of large organisms, like people and elephants.
 - Microevolution describes the evolution of microscopic entities, such as molecules and proteins, while macroevolution describes the evolution of whole organisms.
 - Microevolution describes the evolution of organisms in populations, while macroevolution describes the evolution of species over long periods of time.
 - Microevolution describes the evolution of organisms over their lifetimes, while macroevolution describes the evolution of organisms over multiple generations.
- 5.** Which of the following would be supported by Lamarck?
- a. Natural selection leads to changes in organisms over time
 b. The strong arms of a gorilla are the result of its parents constantly climbing, lifting and fighting.
 c. Lack of resources led to the death of three of four fox cubs.
 d. The founder effect is when a few individuals in a population are separated from the original population.
- 6.** What is population variance influenced by?
- genetic structure
 - environment
 - diet composition
 - All of the above
- 7.** What is genetic variance?
- the change in a population's genetic structure
 - the effect of chance on a population's gene pool
 - the diversity of alleles and genotypes within a population
 - the magnification of genetic drift as a result of natural events or catastrophes
- 8.** When closely related individuals mate with each other, or inbreed, the offspring are often not as fit as the offspring of two unrelated individuals. Why?
- Inbreeding causes normally silent alleles to be expressed.
 - The DNA of close relatives reacts negatively in the offspring.
 - Inbreeding can bring together rare, deleterious mutations that lead to harmful phenotypes
 - Close relatives are genetically incompatible.
- 9.** What could cause genetic drift to occur within a population?
- accidental deaths
 - predators
 - disease
 - lack of gene flow
- 10.** What is the evolutionary mechanism that alters allele frequencies by chance called?
- genetic drift
 - natural selection
 - inbreeding
 - migration
- 11.** What is assortative mating?

- a. when individuals mate with those who are similar to themselves
- b. when individuals mate with those who are dissimilar to themselves
- c. when individuals mate with those who are most fit in the population
- d. when individuals mate with those who are least fit in the population
- 12.** What is an example of a cline?
- a random fluctuation in a species gene frequencies
 - a mutation that spreads across the ecological range of a species
 - the females of a species preferring males that are orange in coloration instead of white
 - a species having greater cold tolerance in the colder parts of its range than in the warmer parts of its range
- 13.** Which type of selection results in greater genetic variance in a population?
- stabilizing selection
 - directional selection
 - diversifying selection
 - positive frequency-dependent selection
- 14.** What types of phenotypes does negative frequency-dependent selection favor?
- advantageous
 - rare
 - common
 - disadvantageous
- 15.** The good genes hypothesis is a theory that explains what?
- why more fit individuals are more likely to have more offspring
 - why alleles that confer beneficial traits or behaviors are selected for by natural selection
 - why some deleterious mutations are maintained in the population
 - why individuals of one sex develop impressive ornament traits
- 16.** Which of the following describes when males and females of a population look or act differently?
- sexual selection
 - diversifying selection
 - sexual dimorphism
 - a cline

CRITICAL THINKING QUESTIONS

- 17.** Describe natural selection and give an example of natural selection at work in a population.
- The process in which genes flow from one population to another. The beak size of Darwin's finches changing as the availability of different-sized seeds changes.
 - The process in which genes flow from one population to another. The Founder Effect occurring among humans immigrating to a new country.
 - The process in which better-adapted organisms are able to survive and reproduce; The beak size of Darwin's finches changing as the availability of different-sized seeds changes.
 - The process in which better-adapted organisms are able to survive and reproduce; The Founder Effect occurring among humans immigrating to a new country.

- 18.** Imagine you are trying to test whether a population of flowers is undergoing evolution. You suspect there is selection pressure on the color of the flower: bees seem to cluster around the red flowers more often than the blue flowers. In a separate experiment, you discover that blue flower color is dominant to red flower color. In a field, you

count 600 blue flowers and 200 red flowers. What would you expect the genetic structure of the flowers to be?

- You would expect 300 homozygous dominant blue flowers, 300 heterozygous blue flowers, and 200 homozygous recessive red flowers.
- You would expect 200 homozygous dominant blue flowers, 400 heterozygous blue flowers, and 200 homozygous recessive red flowers.
- You would expect 100 homozygous dominant red flowers, 100 heterozygous red flowers, and 600 homozygous recessive blue flowers.
- You would expect 14 homozygous dominant red flowers, 186 heterozygous blue flowers, and 600 homozygous recessive blue flowers.

- 19.** What must occur in order for a new trait to appear in a population and then reach a steady, high frequency within that population?

- a. New traits appear through gene mutations or through genetic drift. In order to reach a steady, high frequency in the population, there must be many mutagens, such as UV radiation, in the environment to produce many mutations.
- b. New traits appear through gene mutations or through genetic drift. In order to reach a steady, high frequency in the population, there must be a consistent source of immigrant individuals with the allele.
- c. New traits appear through gene mutations or through evolution. In order to reach a steady, high frequency in the population, the allele must code for a favorable adaptation.
- d. New traits appear through gene mutations or through gene flow. In order to reach a steady, high frequency in the population, the trait associated with the gene must be favored by either natural or sexual selection.
- 20.** Define and identify an example of population variation.
- Population variation is a description of the diversity of different forms of life. An example of population variation would be the different forms and functions of prokaryotes versus eukaryotes.
 - Population variation is the geographic distribution of different phenotypes in a population. An example of population variation would be the fact that warm-blooded mammals that live near the poles tend to be larger than their southern counterparts to conserve heat.
 - Population variation is the distribution of phenotypes in a population. An example of population variation would be the many different fur colors and patterns found in domestic dogs.
 - Population variation is the distribution of genotypes in a population. An example of population variation would be Mendel's pea plants that were homozygous dominant, heterozygous and homozygous recessive for various traits.
- 21.** People who breed domesticated animals try to avoid inbreeding even though most domesticated animals are indiscriminate. Evaluate why this is a good practice.
- a. A breeder would not allow close relatives to mate because inbreeding increases the likelihood of fatal mutations in offspring.
- b. A breeder would not allow close relatives to mate because inbreeding prevents gene flow which can bring new, successful genes into the population.
- c. A breeder would not allow close relatives to mate because inbreeding causes diversifying selection, which dilutes the breeder's desired genes in the population.
- d. A breeder would not allow close relatives to mate because inbreeding can bring together deleterious recessive mutations that can cause abnormalities and susceptibility to disease.
- 22.** Explain the founder effect and identify the best example.

- a. The founder effect is an event that isolates part of a population, generating an allele frequency which is not typical of the original population. An example of the founder effect is the Amish population. The Amish population was established from about 200 German immigrants. Individuals of this founding population carried gene mutations that cause inherited disorders such as Ellis-van Creveld syndrome. This form of dwarfism is found in a large concentration in the Amish population today because the immigrants that established the population had a high concentration of the disorder in a very small population.
- b. The founder effect is an event that kills off a significant proportion of a population, generating an allele frequency which is not typical of the original population. An example of the founder effect is the Northern elephant seal. At one point, hunting of these seals had reduced their numbers to less than 50 individuals. The population has since rebounded, but still contains less genetic variation than the related Southern elephant seal due to the loss of some alleles.
- c. The founder effect is when only a few males within a population are selected by females to reproduce, generating an allele frequency which is different from the original population. An example of the founder effect is the reproductive pattern of mountain gorillas. Mountain gorillas tend to have a single dominant male, the silverback, who gets the vast majority of the matings in the population. This leads to the next generation expressing mainly genes from the silverback and very few genes from the other males, changing the genetic structure of the population.
- d. The founder effect occurs when the selective pressure on a trait varies depending on the alleles expressed within the population, generating varying allele frequencies based on the genetic makeup of the original population. An example of the founder effect is the cyclical dominance of three throat-color patterns in side-blotched lizards.
23. Explain what a cline is and identify an example.
- a. A cline is a type of geographic variation that is seen in populations of a given species that vary gradually across an ecological gradient. For example, endothermic animals tend to have larger bodies in the cooler climates closer to the earth's poles, allowing them to better conserve heat.
- b. A cline is a change in ecological conditions over a geographic distance. For example, a latitudinal cline is the decrease in temperature towards the Earth's poles, and an altitudinal cline is the decrease in temperature with increase in altitude.
- c. A cline is the specific set of traits in a population of a given species that have been influenced by the local environment. For example, a population of warm-blooded animals that lived in a cooler climate closer to the North Pole would have larger bodies, allowing them to better conserve heat.
- d. A cline is the specific set of ecological conditions in a geographic region. For example, towards the North Pole it is cold and there is little precipitation. This will influence the traits of the organisms that live there.
24. The table below shows data for a small population of mice. The mice are either brown or white. Based on the data, is the population experiencing genetic drift? Explain.

Generation	Brown mice	Black mice
1	14	32
2	20	26
3	24	22
4	21	28
5	19	30
6	24	29

Table 19.2

25. The large alpha male elephant seal is constantly fending off the advances of medium sized males. Small males are then able to sneak copulation with females and successfully pass on their genes. What is this an example of? Explain.

- This is an example of sexual selection. The females are selecting the small males over the large male.
- This is an example of genetic drift. Because there are so many medium-sized males to compete with the large alpha male, the small males are able to mate and cause the gene pool to shift towards smaller individuals.
- This is an example of positive frequency-dependent selection, which is selection that favors phenotypes that are either common or rare. The sneaky males (rare) are favored in this case.
- This is an example of directional selection. Because only the smallest males are mating, the next generation will have a higher proportion of alleles for small size, making the seals smaller over time.

26. Explain why there is no perfect organism despite natural selection.

- Because natural selection works on a geographic level.
- Because natural selection works in a random manner like mutations.
- Because of limitations due to a population's existing variation in genes.
- Because natural selection is limited to sexual dimorphism.

27. A new predator invades the habitat of a population of

field mice. Individuals with larger body size are easier for the predator to capture than individuals with smaller body size. Draw a histogram of body sizes with two plot lines, one showing the former population and another showing the new population that indicates how this population will likely evolve. On your histogram, also indicate what type of natural selection is occurring here.

28. Quinine is an antimalarial drug that is used to treat malaria in the Western Hemisphere. Scientists have noticed that this drug has become less effective over time. Based on the data below, what type of selection is being exerted on the malaria population?

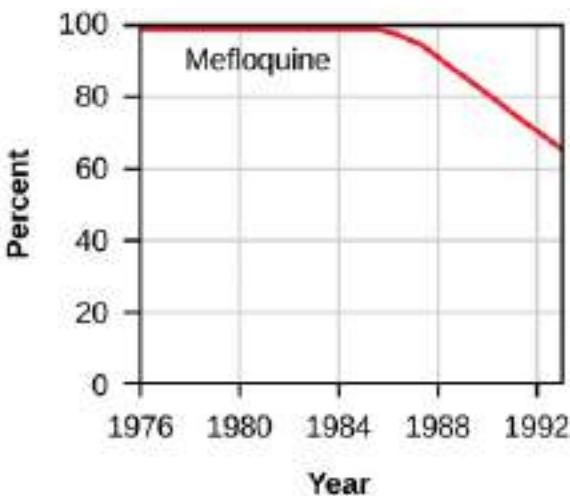

Figure 19.12

TEST PREP FOR AP® COURSES

29. A scientist is studying the genetics of a population of plants that she suspects is undergoing natural selection. After examining samples of the population's DNA over several years, she finds the following data:

Year	Allele A Frequency	Allele B Frequency
1	0.80	0.2
2	0.72	0.28
3	0.66	0.34
4	0.52	0.48
5	0.45	0.55
6	0.39	0.61

Does this provide evidence of natural selection in this population? Why or why not?

- No, because the genotype frequencies, not allele frequencies, have to change for evolution to occur.
- No, because the allele frequencies are changing randomly, suggesting that genetic drift is occurring, not natural selection.
- Yes, because it shows that the previously favorable or neutral allele A is now being selected against in favor of allele B.
- Yes, because it is showing that the frequency of both alleles are changing over time.

30. A scientist is studying two large populations of deer that are centralized in nearby forests. She takes blood samples from all of the deer in each population and records in how many individuals she finds allele A. She then computes the frequency of the alleles in each population. The frequencies observed over five years are shown in the tables below.

Year	Population A	
	Allele A Frequency	Allele B Frequency
1	0.69	0.20
2	0.71	0.29
3	0.73	0.27
4	0.75	0.25
5	0.81	0.19
6	0.84	0.16

Year	Population B	
	Allele A Frequency	Allele B Frequency
1	0.00	1.00
2	0.00	1.00
3	0.10	0.90
4	0.16	0.84
5	0.21	0.79
6	0.25	0.75

Which forms of evolution are most likely occurring in populations A and B? Explain your answer.

- In population A, genetic drift is likely occurring, causing allele A to become more prevalent than allele B. In population B, mutation apparently occurred, introducing allele A to population B. Allele A also appears to be increasing due to genetic drift in population B.
- In population A, natural selection is likely occurring, with allele A being favored over allele B. In population B, gene flow apparently occurred, allowing allele A to become established in population B. Allele A also appears to be favored by selection in population B.
- In population A, gene flow apparently occurred, allowing allele B to become established in population A. Allele A also appears to be favored by selection in population A. In population B genetic drift is likely occurring, causing allele A to become more prevalent than allele B.
- In population A, mutation apparently occurred, introducing allele B to population A. Allele A also appears to be increasing due to genetic drift in population A. In population B natural selection is likely occurring, with allele A being favored over allele B.

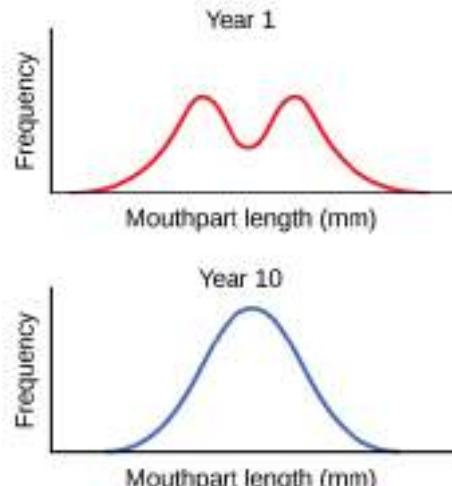

31. A land manager mows a section of annual grass. Over the years, he recorded the date of flowering from the mown field as well as a similar grass field that was not mown. What is the most likely explanation for this trend?

Year	Mowed field flowering date	Unmowed field flowering date
2010	7/29	7/28
2011	7/20	7/26
2012	7/13	8/1
2013	7/8	7/29
2014	7/1	8/2
2015	6/29	7/26

- The grass population is adapting to the mowing, so it can flower for longer before being mowed.
- Mowing stabilizes the flowering time, which follows a steady trend in the mowed field but not in the unmowed field.
- The mowing is preventing the grass from reproducing, causing the mowed field to adapt by flowering earlier.
- The grass typically flowers earlier and earlier every year as it becomes older with each passing year.

32. A scientist observed two populations of insects for 10 years. They took data on the length, in mm, of the insect's mouthparts. Their data is shown in the graphs below. How is this population evolving and what agent of evolution is most likely at work?

Distribution of Insect Mouthpart Lengths Throughout the Population Years 1 and 10

- a. inbreeding, because the gene distributions are becoming less similar among the population
- b. genetic drift, as the distribution of traits has become more random
- c. gene flow, as the population has likely gained new mouthpart traits through immigration
- d. natural selection, as insects that have mid-sized mouthparts are being favored

33. A pond is stocked with 250 fish, all of the same species. At that time, the researchers tested the fish to determine if they were genetically predisposed to a certain disease. The gene tested has two alleles, A and a. They found that 58 of the fish possessed allele A, while the rest of the fish possessed allele a. They plan to reassess the fish 5 years later. A computer model predicts that the population will likely increase to 850 fish and have 403 heterozygote (Aa) individuals. Will the future population have evolved? State how you know.

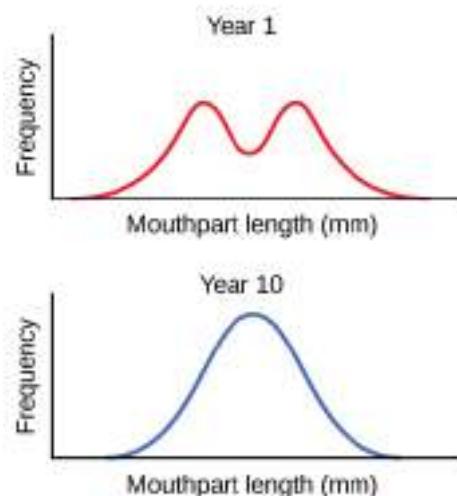

- a. Evolution has not occurred, because the frequency of the heterozygotes is different 5 years later compared with the original population.
- b. Evolution has not occurred, because the frequency of the heterozygotes is different 5 years later as in the original population.
- c. Evolution has not occurred, because the frequency of the heterozygotes is the same 5 years later as in the original population.
- d. Evolution has occurred, because the frequency of the heterozygotes is different 5 years later compared with the original population.

34. Heterozygote advantage is a condition in which heterozygotes are favored by natural selection. How would the value of $2pq$ likely change if the population was undergoing heterozygote advantage?

- a. It would remain in equilibrium because the value of p and q would remain the same.
- b. It would remain in equilibrium because the value of $2pq$ would remain the same.
- c. It would not remain in equilibrium because the value of $2pq$ would likely increase.
- d. It would not remain in equilibrium because the value of $2pq$ would likely decrease.

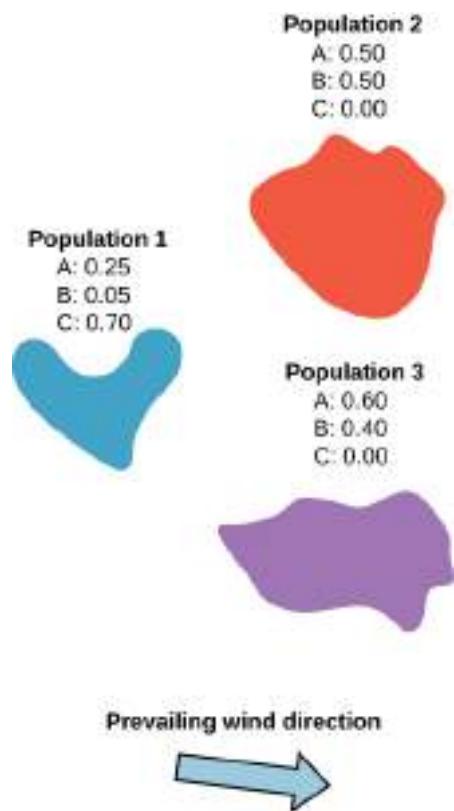

35. The graph below shows the change in gene frequency of the two alleles of a gene: A and a. The population being studied has no emigration or immigration. Which type of evolution is likely occurring here and is the allele selected for, neutral, or selected against by natural selection?

Distribution of Insect Mouthpart Lengths Throughout the Population Years 1 and 10

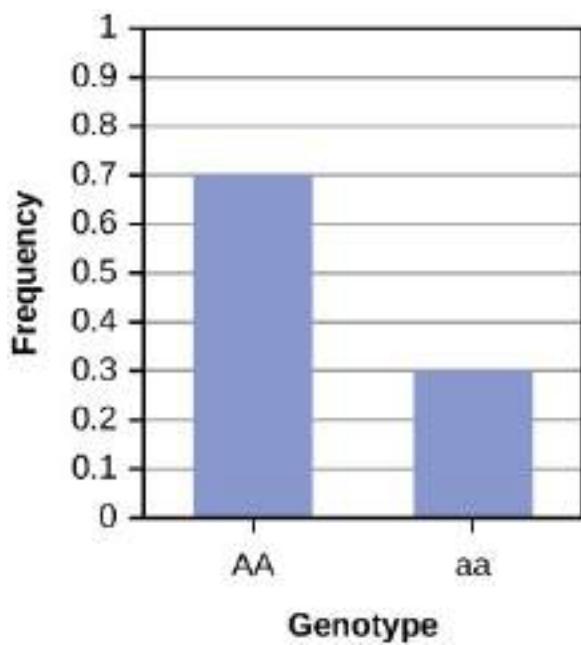

- a. non-random mating; both alleles are favored
- b. gene flow; allele A is favored
- c. genetic drift; both alleles are neutral
- d. natural selection; allele a is not favored

36. The graph below shows the change in gene frequency of the two alleles: A and B. These alleles are located on separate genes that do not influence each other in any way. The population being studied has no emigration or immigration. Which type of evolution is likely occurring here, if at all? Explain how you know.

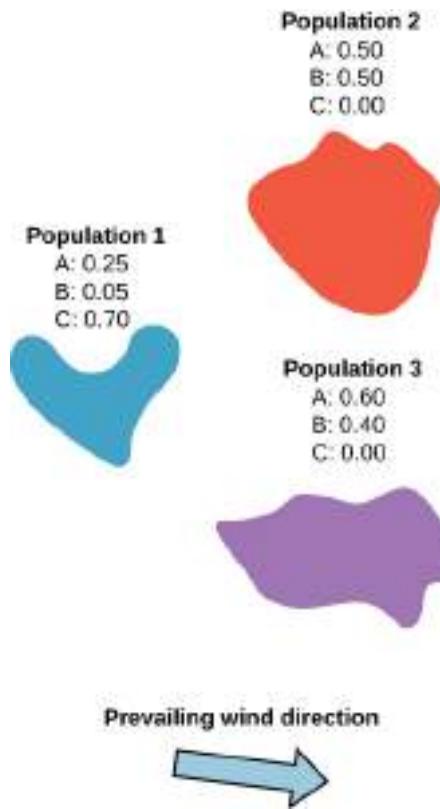

- a. no multiple choice available
- b. no multiple choice available

37. The graph below shows the current frequencies of two genotypes of the same gene: AA and aa. What would most likely happen to the frequencies of A and a if heterozygous individuals were favored by natural selection?

- a. Both AA and aa will drop in frequency by the same amount.
- b. Both AA and aa will drop, but aa will drop more.
- c. AA will increase in frequency and aa will drop in frequency.
- d. aa will increase in frequency and AA will drop in frequency.

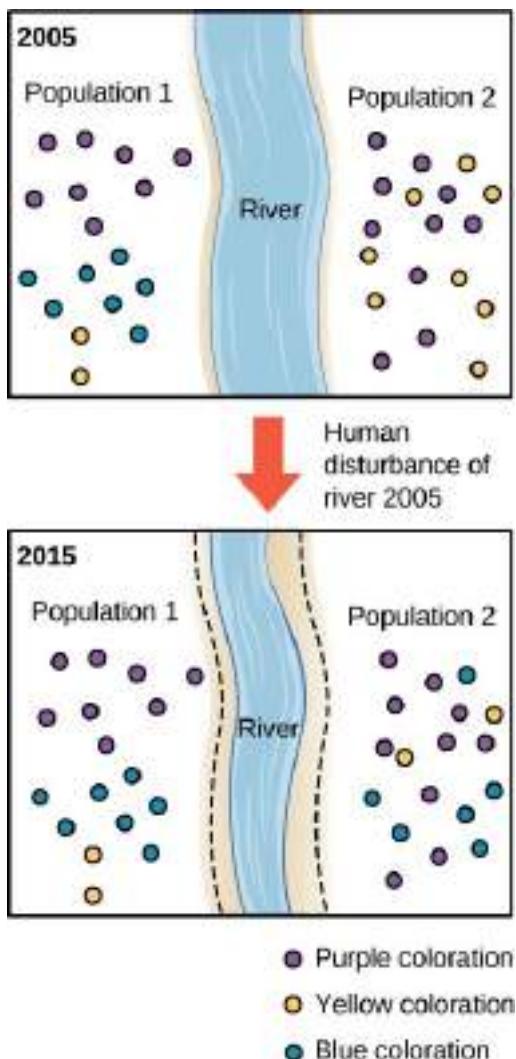

38. The diagram below shows the frequency of alleles on two species of wind-pollinated plants, as well as the prevailing wind direction. These frequencies have been fairly stable for around 10 years. However, climate change has created a new prevailing wind direction, as shown in the diagram. How will the two populations likely evolve in the future?

- a. natural selection will cause the frequency of B to increase in population 1
- b. gene flow will cause the frequencies of A and B to drop in population 3
- c. genetic drift will cause the frequencies of A and C to increase in population 1 and 2
- d. inbreeding will reduce the frequency of allele B in population 2 and 3

39. The diagram below shows two populations of organisms that have been long-separated by a river which prevents interbreeding. The two populations differ in coloration, as shown in the diagram. Recent human

activity has caused the river to dry, however, resulting in the two populations shown in the lower diagram. What is the most likely explanation for this change?

- an increase in gene flow between the two populations
- a decrease in gene flow between the two populations
- an increase in non-random mating between the two populations
- a decrease in non-random mating between the two populations

40. Antibiotics are medicines that are designed to kill disease-causing organisms, or pathogens. However, some pathogens evolve antibiotic resistance, where they gain traits that allow them to survive in the presence of antibiotics. The ability of bacteria to adapt to antibiotics so quickly has created a huge concern over whether antibiotics are being overused. What form of evolution is antibiotic resistance an example of, and why?

- Gene flow because the bacteria are passing on the resistant trait within their populations.
- Natural selection, because the bacteria is adapting to a new environmental condition - the presence of the antibiotic.
- Genetic drift because medical workers cannot follow the randomly-fluctuating gene frequencies of bacterial populations
- Mutation, because each bacteria must mutate to an antibody resistant form in order to survive.

SCIENCE PRACTICE CHALLENGE QUESTIONS

41. Consider a polymorphic gene with three alleles: A, B, and C.

A. If the frequencies of the alleles A and B are 0.2 and 0.3, the frequency of allele C is closest to ____.

- 0.25
- 0.5
- 0.2
- 0.3

Consider a gene with only two alleles: dominant A and recessive a. In a population of 1,000 organisms, the fraction expressing the homozygous recessive phenotype is 0.37.

B. The calculated allele frequencies p and q have values that are closest to ____.

- 0.69 and 0.31
- 0.31 and 0.69
- 0.37 and 0.63
- 0.63 and 0.37

Genotype	C ₁	C ₂	C ₃	C ₁	C ₁	C ₂	C ₃	Total
Observed	120	230	112	175	198	165	1,000	

Table 19.3

C. The calculated number of individuals in this population that are heterozygotes is closest to ____.

- a. 240
- b. 230
- c. 430
- d. 476

Mountain pine beetles (*Dendroctonus ponderosae*) were collected from a one-acre tract of lodge pole pine trees (*Pinus contorta*) in a region of British Columbia where the forests are under temperature stress. The beetles were crushed, and a cellulase enzyme was extracted. Three polymorphs of the enzyme were observed when separated by gel electrophoresis. The three proteins observed correspond to alleles labeled C₁, C₂, and C₃. The numbers of beetles with each allele are shown in the following table.

D. The calculated allelic frequencies p_{C1}, p_{C2}, and p_{C3} are closest to ____.

- a. p_{C1} = 0.57 p_{C2} = 0.57 p_{C3} = 0.59
- b. p_{C1} = 0.29 p_{C2} = 0.29 p_{C3} = 0.42
- c. p_{C1} = 0.61 p_{C2} = 0.80 p_{C3} = 0.59
- d. p_{C1} = 0.31 p_{C2} = 0.40 p_{C3} = 0.29

E. In order to investigate the presence of selection at the cellulase locus due to changing temperature, a biologist should:

- a. calculate the values of the sums p_{C1} + p_{C2} + p_{C3} and (p_{C1} + p_{C2} + p_{C3})². If these numbers are not equal to 1, the gene is not in Hardy-Weinberg equilibrium, and the gene is evolving.
- b. return next year and repeat this examination of the enzyme, calculating frequencies of each allele each year. Then calculate the values of the sums p_{C1} + p_{C2} + p_{C3} and (p_{C1} + p_{C2} + p_{C3})². If these numbers are not the same each year, the gene is not in Hardy-Weinberg equilibrium, and the gene is evolving.
- c. return each year for several years and repeat this examination of the enzyme, calculating frequencies of each allele each year. If the allele frequencies are changing, the gene is not in Hardy-Weinberg equilibrium, and temperature is exerting a selection pressure.
- d. return each year for several years and repeat this examination of the enzyme, calculating frequencies of each allele each year. If the allele frequencies are changing, the gene is not in Hardy-Weinberg equilibrium. Analysis of the dependence of allele frequencies on temperature could indicate selection.

42. *Calanus finmarchicus* is the dominant copepod in the Gulf of Maine. The polymorphic aminopeptidase locus, Lap-1, has been shown to be useful for the genetic differentiation of populations of this organism. By examining the population dynamics of copepods, the dynamics of the fin fish on which they feed can be

predicted. The aerial photograph shows a landmass separating two coastal estuarine habitats, the mud flats of Egypt Bay and the Mount Desert Narrows. For the past 40 years, transport between the two habitats has been hindered by a dam over the Carrying Place Inlet. However, small volumes of water occasionally crest the dam.

Figure 19.13

To evaluate the geographic isolation of invertebrate populations in these two habitats, copepods are sampled at the points labeled 1 and 2 on the photograph. These points lie at either ends of the Carrying Place Inlet. Enzymes encoded by three alleles, labeled A, B, and C, were determined by gel electrophoresis of equal numbers of the organisms collected at the two sites. Numbers of each genotype are given in the following table:

Site	1	2
AA	82	96
AB	114	108
AC	102	92
BB	74	54
BC	98	110
CC	30	40
Total	500	500

Table 19.4

A. Calculate the frequencies, f, of each allele and complete the following table:

Site	f(A)	f(B)	f(C)
1			
2			

Table 19.5

B. Using a χ^2 test, **evaluate** these data to determine if the aminopeptidase gene in these two populations is evolving. State your conclusion as claims supported by evidence at both the 95% and 99% confidence levels. The formula for the χ^2 test is provided on the AP Biology Exam.

$$\chi^2 = \sum \frac{(o - e)^2}{e}$$

This table of critical p values is also provided on the AP Biology Exam.

Degrees of Freedom								
p	1	2	3	4	5	6	7	8
0.05	3.84	5.99	7.82	9.49	11.07	12.59	14.07	15.51
0.01	6.64	9.32	11.34	13.28	15.09	16.81	18.48	20.09

Table 19.6

C. Based on these data, **predict**, with justification, changes over time in the aminopeptidase enzyme for these populations.

D. The B form of this aminopeptidase is slightly more efficient at extracting nutritional leucine from a protein than the A and C forms but slightly less efficient at extracting valine and serine. **Describe** an investigation of the two habitats that could suggest a causal relationship between changes in allele frequency and characteristics of the environment.

E. Single-nucleotide mutations are neutral when they encode changes in proteins that result in no significant differential selection. If differences in environmental factors between sites 1 and 2 are not observed, **predict** what other factors could result in departures from Hardy-Weinberg equilibrium for aminopeptidase.

43. Bioluminescence is an example of convergent evolution; 30 distinct lineages have acquired this characteristic, and all involve some form of a class of molecules called luciferins. Sexual selection pressures are strong for light-emitting organisms. Ellis and Oakley (*Curr Biol*, 2016) examined the number of species that lack luminosity in groups of closest evolutionary relation (sister lineage) with those species that are luminous. Similarly, scientists made the same comparison between groups that use luminosity for concealment (counter-illumination) and their sister lineages. The graphs

summarize their results, comparing the natural logarithm of the number of species in each lineage.

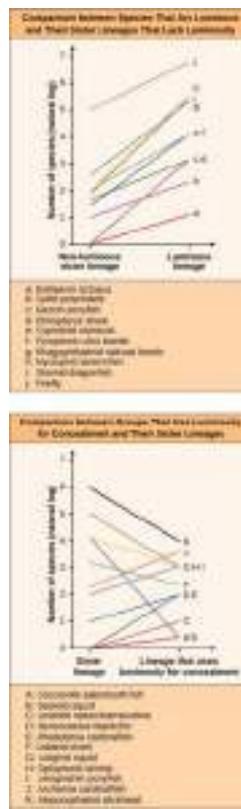

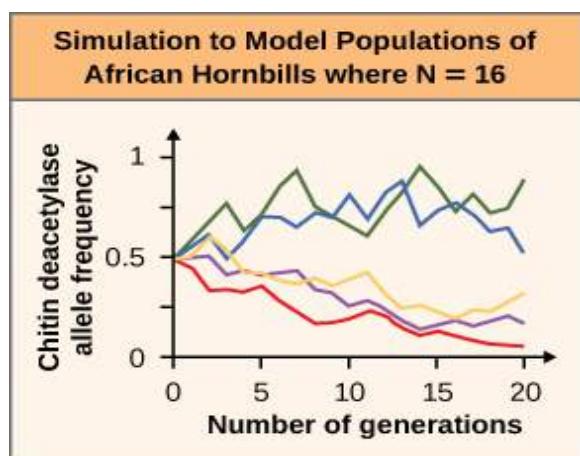

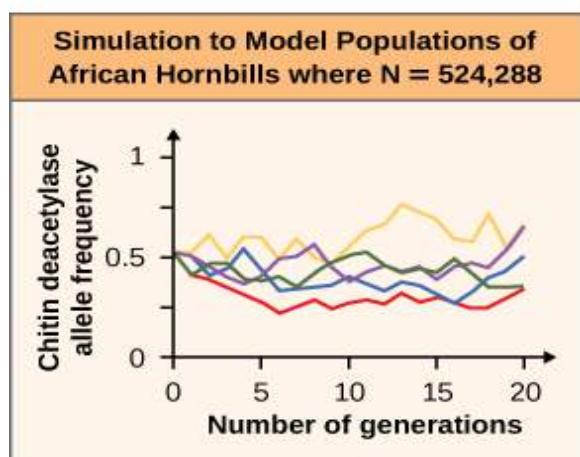

Figure 19.14

Based on the data shown in the graphs, **describe** a model that can account for the increased speciation of bioluminescent lineages, including the mechanism of speciation.

44.

(a)

(b)

Figure 19.15 A biologist is using a simulation to model populations of African hornbills (*Bycanistes* spp. and *Ceratogymna* spp.), a keystone species of the savanna. Populations of the birds are declining due to habitat loss. The hornbill's diet consists primarily of termites and fruit. A critical component of termite digestion is chitin deacetylase, an enzyme whose mutation rate is a model parameter. The other model parameter is population size, N . In the results of the simulation study shown above, there is no selection, and the mutation rate is fixed. Although both population size and mutation rate are fixed, randomness results in the five different outcomes shown in each graph above.

- Select the graph displaying the results that are closer to Hardy-Weinberg equilibrium. Justify the selection of the graph.
- Based on these simulations, predict the future heterozygosity, $2pq$, of the smaller populations, as shown in graph A.
- Justify the use of a simulation study with no selection under environmental conditions in which the availability of both termites and fruit is high.
- If a change in the environment occurs suddenly, such as an increase in average temperature, where fruit production declines, analyze the effect of the change on allele frequency in the large and small populations.

20 | PHYLOGENIES AND THE HISTORY OF LIFE

Figure 20.1 The life of a bee is very different from the life of a flower, but the two organisms are related. Both are members of the domain Eukarya and have cells containing many similar organelles, genes, and proteins. (credit: modification of work by John Beetham)

Chapter Outline

- 20.1: Organizing Life on Earth**
- 20.2: Determining Evolutionary Relationships**
- 20.3: Perspectives on the Phylogenetic Tree**

Introduction

This bee and *Echinacea* flower (Figure 20.1) could not look more different, yet they are related, as are all living organisms on Earth. By following pathways of similarities and changes—both visible and genetic—scientists seek to map the evolutionary past of how life developed from single-celled organisms to the tremendous variety of creatures that have germinated, crawled, floated, swam, flown, and walked on this planet.

New species are discovered with frequent regularity, but it's not too common to discover a new large mammal. However, that's what scientists did in Australia when they named a new species of cetacean the Australian humpback dolphin, *Sousa sahulensis*. The dolphin had originally been classified as another closely related species, but a closer look at its coloration, skeletal structure, habitat, and DNA determined that it was in fact a separate species.

For more information, read the **research article** (<http://openstaxcollege.org/l/32dolphin>) yourself.

20.1 | Organizing Life on Earth

In this section, you will explore the following questions:

- Why do scientists need a comprehensive classification system to study living organisms?
- What are the different levels of the taxonomic classification system?
- How are systematics and taxonomy related to phylogeny?
- What are the components and purpose of a phylogenetic tree?

Connection for AP® Courses

In prior chapters we explored how all organisms on Earth, extant and extinct, evolved from common ancestry. Supporting this claim are core features and processes, such as a common genetic code and metabolic pathways, which evolved billions of years ago and are widely distributed among organisms living today. The evolutionary history and relationship of an organism or a group of organisms is called **phylogeny**. Scientists often construct **phylogenetic trees** based on evidence drawn from multiple disciplines to illustrate evolutionary pathways and connections among organisms.

Scientists historically organized Earth's millions of species into a hierarchical **taxonomic classification system** from the most inclusive category to the most specific: domain, kingdom, phylum, class, order, family, genus, and species. The traditional five-kingdom system that you might have studied in middle school was expanded (and reorganized) to include three domains: Bacteria, Archaea, and Eukarya, with prokaryotes divided between Bacteria or Archaea depending on their molecular genetic machinery, and protists, fungi, plants, and animals grouped in Eukarya. Today, however, phylogenetic trees provide more specific information about evolutionary history and relationships among organisms. (For the purpose of AP®, you do not have to memorize the taxonomic levels. However, it is important to reiterate that taxonomy is a tool to organize the millions of organisms on Earth, similar to how items in a grocery store or mall shop are organized into different departments. Like new products, organisms are often shifted among their taxonomic groups!)

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Big Idea 1	The process of evolution drives the diversity and unity of life.
Enduring Understanding 1.B	Organisms are linked by lines of descent from common ancestry.
Essential Knowledge	1.B.1 Organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Science Practice	3.1 The student can pose scientific questions.
Learning Objective	1.14 The student is able to pose scientific questions that correctly identify essential properties of shared, core life processes that provide insight into the history of life on Earth.
Essential Knowledge	1.B.1 Phylogenetic trees and cladograms are graphical representations (models) of evolutionary history that can be tested.
Science Practice	7.2 The student can connect concepts in and across domain(s) to generalize or extrapolate in and/or across enduring understandings and/or big ideas.
Learning Objective	1.15 The student is able to describe specific examples of conserved core biological processes and features shared by all domains or within one domain of life, and how these shared, conserved core processes and features support the concept of common ancestry for all organisms.

Essential Knowledge	1.B.1 Organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Science Practice	6.1 The student can justify claims with evidence.
Learning Objective	1.16 The student is able to justify the scientific claim that organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Essential Knowledge	1.B.2 Phylogenetic trees and cladograms are graphical representations (models) of evolutionary history that can be tested.
Science Practice	3.1 The student can pose scientific questions.
Learning Objective	1.17 The student is able to pose scientific questions about a group of organisms whose relatedness is described by a phylogenetic tree or cladogram.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 1.20][APLO 1.26]

Phylogenetic Trees

Scientists use a tool called a phylogenetic tree to show the evolutionary pathways and connections among organisms. A phylogenetic tree is a diagram used to reflect evolutionary relationships among organisms or groups of organisms. Scientists consider phylogenetic trees to be a hypothesis of the evolutionary past since one cannot go back to confirm the proposed relationships. In other words, a “tree of life” can be constructed to illustrate when different organisms evolved and to show the relationships among different organisms (Figure 20.2).

Unlike a taxonomic classification diagram, a phylogenetic tree can be read like a map of evolutionary history. Many phylogenetic trees have a single lineage at the base representing a common ancestor. Scientists call such trees **rooted**, which means there is a single ancestral lineage (typically drawn from the bottom or left) to which all organisms represented in the diagram relate. Notice in the rooted phylogenetic tree that the three domains—Bacteria, Archaea, and Eukarya—diverge from a single point and branch off. The small branch that plants and animals (including humans) occupy in this diagram shows how recent and minuscule these groups are compared with other organisms. Unrooted trees don’t show a common ancestor but do show relationships among species.

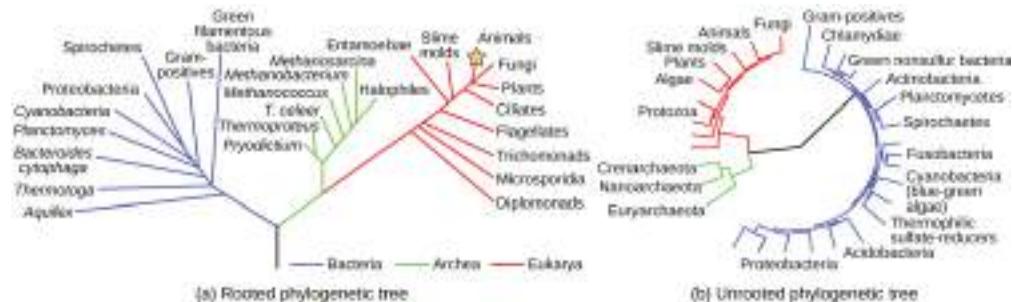

Figure 20.2 Both of these phylogenetic trees shows the relationship of the three domains of life—Bacteria, Archaea, and Eukarya—but the (a) rooted tree attempts to identify when various species diverged from a common ancestor while the (b) unrooted tree does not. (credit a: modification of work by Eric Gaba)

In a rooted tree, the branching indicates evolutionary relationships (Figure 20.3). The point where a split occurs, called a **branch point**, represents where a single lineage evolved into a distinct new one. A lineage that evolved early from the root and remains unbranched is called **basal taxon**. When two lineages stem from the same branch point, they are called **sister taxa**. A branch with more than two lineages is called a **polytomy** and serves to illustrate where scientists have not definitively determined all of the relationships. It is important to note that although sister taxa and polytomy do share an ancestor, it does not mean that the groups of organisms split or evolved from each other. Organisms in two taxa may have split apart at a specific branch point, but neither taxa gave rise to the other.

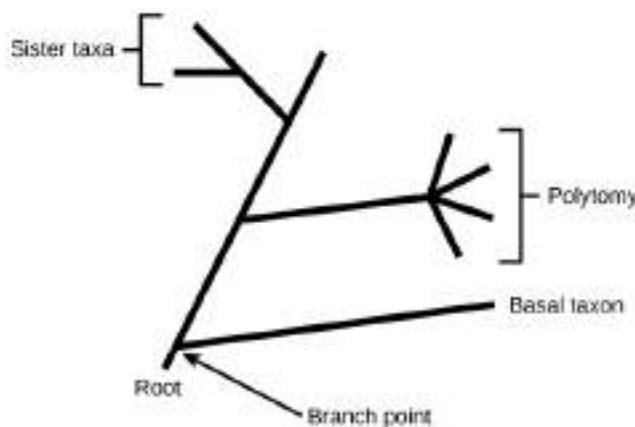

Figure 20.3 The root of a phylogenetic tree indicates that an ancestral lineage gave rise to all organisms on the tree. A branch point indicates where two lineages diverged. A lineage that evolved early and remains unbranched is a basal taxon. When two lineages stem from the same branch point, they are sister taxa. A branch with more than two lineages is a polytomy.

The diagrams above can serve as a pathway to understanding evolutionary history. The pathway can be traced from the origin of life to any individual species by navigating through the evolutionary branches between the two points. Also, by starting with a single species and tracing back towards the "trunk" of the tree, one can discover that species' ancestors, as well as where lineages share a common ancestry. In addition, the tree can be used to study entire groups of organisms.

Another point to mention on phylogenetic tree structure is that rotation at branch points does not change the information. For example, if a branch point was rotated and the taxon order changed, this would not alter the information because the evolution of each taxon from the branch point was independent of the other.

Many disciplines within the study of biology contribute to understanding how past and present life evolved over time; these disciplines together contribute to building, updating, and maintaining the "tree of life." Information is used to organize and classify organisms based on evolutionary relationships in a scientific field called **systematics**. Data may be collected from fossils, from studying the structure of body parts or molecules used by an organism, and by DNA analysis. By combining data from many sources, scientists can put together the phylogeny of an organism; since phylogenetic trees are hypotheses, they will continue to change as new types of life are discovered and new information is learned.

Limitations of Phylogenetic Trees

It may be easy to assume that more closely related organisms look more alike, and while this is often the case, it is not always true. If two closely related lineages evolved under significantly varied surroundings or after the evolution of a major new adaptation, it is possible for the two groups to appear more different than other groups that are not as closely related. For example, the phylogenetic tree in **Figure 20.4** shows that lizards and rabbits both have amniotic eggs, whereas frogs do not; yet lizards and frogs appear more similar than lizards and rabbits.

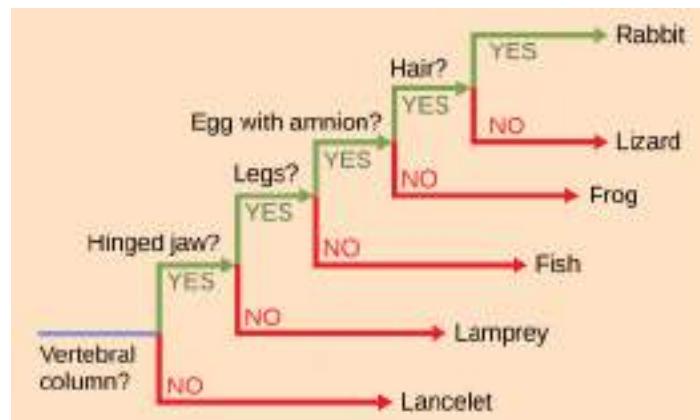

Figure 20.4 This ladder-like phylogenetic tree of vertebrates is rooted by an organism that lacked a vertebral column. At each branch point, organisms with different characters are placed in different groups based on the characteristics they share.

Another aspect of phylogenetic trees is that, unless otherwise indicated, the branches do not account for length of time, only the evolutionary order. In other words, the length of a branch does not typically mean more time passed, nor does a short branch mean less time passed—unless specified on the diagram. For example, in **Figure 20.4**, the tree does not indicate how much time passed between the evolution of amniotic eggs and hair. What the tree does show is the order in which things took place. Again using **Figure 20.4**, the tree shows that the oldest trait is the vertebral column, followed by hinged jaws, and so forth. Remember that any phylogenetic tree is a part of the greater whole, and like a real tree, it does not grow in only one direction after a new branch develops. So, for the organisms in **Figure 20.4**, just because a vertebral column evolved does not mean that invertebrate evolution ceased; it only means that a new branch formed. Also, groups that are not closely related, but evolve under similar conditions, may appear more phenotypically similar to each other than to a close relative.

Head to this [website](http://openstaxcollege.org/l/tree_of_life) (http://openstaxcollege.org/l/tree_of_life) to see interactive exercises that allow you to explore the evolutionary relationships among species.

What is the main function of the iTOL (Interactive Tree of Life) website?

- iTOL is a website that provides the history about the Tree of Life.
- iTOL is a website that provides guidelines for researching data to create a phylogenetic tree.
- iTOL is an online tool that provides the display and manipulation of pre-computed phylogenetic trees, and you can upload and display your own trees and data.
- iTOL is a website that explains the evolutionary relationships among species.

science practices CONNECTION for AP[®] Courses

Think About It

How does a phylogenetic tree relate to the passing of time? What other questions about the evolutionary history of an organism and its relatedness to other organisms can a phylogenetic tree answer?

The Levels of Classification

Taxonomy (which literally means “arrangement law”) is the science of classifying organisms to construct internationally shared classification systems with each organism placed into more and more inclusive groupings. Think about how a grocery store is organized. One large space is divided into departments, such as produce, dairy, and meats. Then each department further divides into aisles, then each aisle into categories and brands, and then finally a single product. This organization from larger to smaller, more specific categories is called a hierarchical system.

The taxonomic classification system (also called the Linnaean system after its inventor, Carl Linnaeus, a Swedish botanist, zoologist, and physician) uses a hierarchical model. Moving from the point of origin, the groups become more specific, until one branch ends as a single species. For example, after the common beginning of all life, scientists divide organisms into three large categories called a domain: Bacteria, Archaea, and Eukarya. Within each domain is a second category called a **kingdom**. After kingdoms, the subsequent categories of increasing specificity are: **phylum, class, order, family, genus, and species** (**Figure 20.5**).

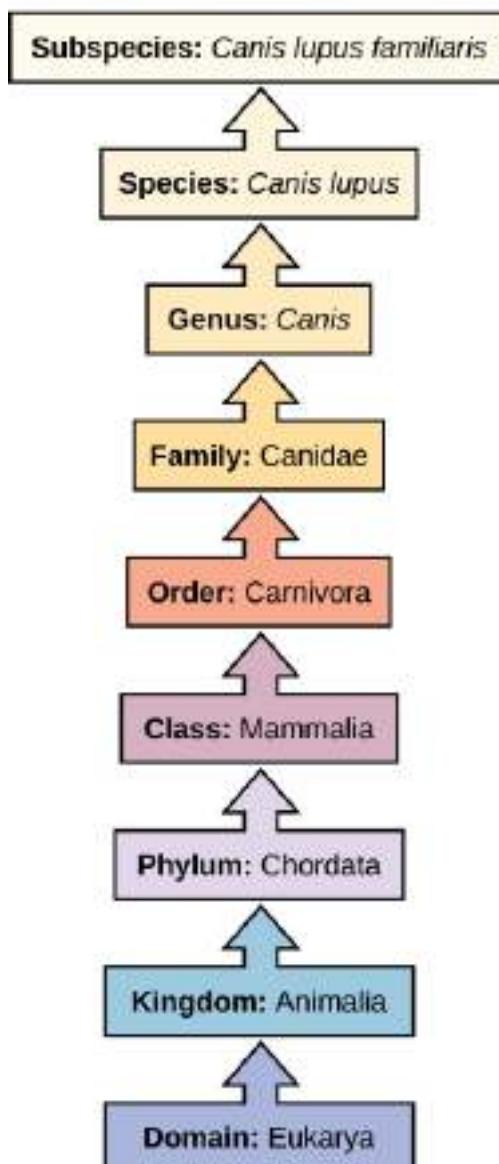

Figure 20.5 The taxonomic classification system uses a hierarchical model to organize living organisms into increasingly specific categories. The common dog, *Canis lupus familiaris*, is a subspecies of *Canis lupus*, which also includes the wolf and dingo. (credit "dog": modification of work by Janneke Vreugdenhil)

The kingdom Animalia stems from the Eukarya domain. For the common dog, the classification levels would be as shown in **Figure 20.5**. Therefore, the full name of an organism technically has eight terms. For the dog, it is: Eukarya, Animalia, Chordata, Mammalia, Carnivora, Canidae, *Canis*, and *lupus*. Notice that each name is capitalized except for species, and the genus and species names are italicized. Scientists generally refer to an organism only by its genus and species, which is

its two-word scientific name, in what is called **binomial nomenclature**. Therefore, the scientific name of the dog is *Canis lupus*. The name at each level is also called a **taxon**. In other words, dogs are in order Carnivora. Carnivora is the name of the taxon at the order level; Canidae is the taxon at the family level, and so forth. Organisms also have a common name that people typically use, in this case, dog. Note that the dog is additionally a subspecies: the “*familiaris*” in *Canis lupus familiaris*. Subspecies are members of the same species that are capable of mating and reproducing viable offspring, but they are considered separate subspecies due to geographic or behavioral isolation or other factors.

Figure 20.6 shows how the levels move toward specificity with other organisms. Notice how the dog shares a domain with the widest diversity of organisms, including plants and butterflies. At each sublevel, the organisms become more similar because they are more closely related. Historically, scientists classified organisms using characteristics, but as DNA technology developed, more precise phylogenies have been determined.

visual CONNECTION

Subspecies: *Canis lupus familiaris*

Species: *Canis lupus*

Genus: *Canis*

Family: Canidae

Order: Carnivora

Class: Mammalia

Phylum: Chordata

Kingdom: Animals

Domain: Eukarya

Figure 20.6 At each sublevel in the taxonomic classification system, organisms become more similar. Dogs and wolves are the same species because they can breed and produce viable offspring, but they are different enough to be classified as different subspecies. (credit "plant": modification of work by "berduchwal"/Flickr; credit "insect": modification of work by Jon Sullivan; credit "fish": modification of work by Christian Mehlführer; credit "rabbit": modification of work by Aidan Wojtas; credit "cat": modification of work by Jonathan Lidbeck; credit "fox": modification of work by Kevin Bacher, NPS; credit "jackal": modification of work by Thomas A. Hermann, NBII, USGS; credit "wolf": modification of work by Robert Dewar; credit "dog": modification of work by "digital_image_fan"/Flickr)

At what levels are cats and dogs considered to be part of the same group?

- Cats and dogs are only found together in the Domain level.
- Cats and dogs are in the same group beginning at the Domain level and including the sublevels Kingdom, Phylum, Class, and Order.
- Cats and dogs are in the same group beginning at the Family level.
- Cats and dogs are part of the same group beginning with the Order: Carnivora level.

Visit this [website](http://openstaxcollege.org/l/classify_life) (http://openstaxcollege.org/l/classify_life) to classify three organisms—bear, orchid, and sea cucumber—from kingdom to species. To launch the game, under Classifying Life, click the picture of the bear or the Launch Interactive button.

Using the taxonomic classification system, which Kingdom category best describes a bear?

- a. Plantae: Multicellular organisms that get their energy through photosynthesis.
- b. Animalia: Multicellular organisms that get their energy through ingesting other organisms.
- c. Fungi: Single-celled and multi-celled organisms that get their energy mainly by absorbing nutrients from their surroundings and not through photosynthesis.

Recent genetic analysis and other advancements have found that some earlier phylogenetic classifications do not align with the evolutionary past; therefore, changes and updates must be made as new discoveries occur. Recall that phylogenetic trees are hypotheses and are modified as data becomes available. In addition, classification historically has focused on grouping organisms mainly by shared characteristics and does not necessarily illustrate how the various groups relate to each other from an evolutionary perspective. For example, despite the fact that a hippopotamus resembles a pig more than a whale, the hippopotamus may be the closest living relative of the whale.

20.2 | Determining Evolutionary Relationships

- What is the difference between homologous and analogous traits? How are these traits used when determining evolutionary relatedness?
- What is cladistics? How does a cladogram differ from a phylogenetic tree?
- What is parsimony?

Connection for AP[®] Courses

To build phylogenetic trees, scientists must collect accurate information that allows them to make evolutionary connections among organisms. Using morphological and molecular data, scientists identify both homologous and analogous characteristics and genes. (In a prior chapter we explored the differences between homologous and analogous traits and how they relate to convergent and divergent evolution.) Similarities among organisms stem either from shared ancestral history (homologies) or from separate evolutionary paths (analogies). **Cladograms** are constructed by using shared derived traits to distinguish different groups of species from one another. For example, lizards, rabbits and humans all descended from a common ancestor that had an amniotic egg; thus, lizards, rabbits, and humans all belong to the same clade. Vertebrata is a larger clade that also includes fish, lamprey, and lancelets. The closer two species or groups are located to each on a phylogenetic tree or cladogram, the more recently they shared a common ancestor. With the influx of new information, scientists can revise phylogenetic trees; for example, computer programs, such as one called BLAST, which helps determine relatedness using DNA sequencing. Typically, a phylogenetic tree is constructed with the simplest explanation of evolutionary history (maximum **parsimony**) and the fewest number of evolutionary steps.

Understanding phylogeny extends far beyond understanding the evolutionary history of species on Earth. For botanists, phylogeny acts as a guide to discovering new plants that can be used to make food, medicine, and clothing. For doctors, phylogenies provide information about the origin of diseases and how to treat them, for example, HIV/AIDS.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 of the AP[®] Biology Curriculum Framework. The AP[®] Learning Objectives listed in the Curriculum Framework provide a transparent

foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Big Idea 1	The process of evolution drives the diversity and unity of life.
Enduring Understanding 1.A	Change in the genetic makeup of a population over time is evolution.
Essential Knowledge	1.A.4 Biological evolution is supported by scientific evidence from many disciplines, including mathematics.
Science Practice	5.3 The student can evaluate the evidence provided by data sets in relation to a particular scientific question.
Learning Objective	1.9 The student is able to evaluate evidence provided by data from many scientific disciplines that support biological evolution.
Essential Knowledge	1.A.4 Biological evolution is supported by scientific evidence from many disciplines, including mathematics.
Science Practice	5.2 The student can refine observations and measurements based on data analysis.
Learning Objective	1.10 The student is able to refine evidence based on data from many scientific disciplines that support biological evolution.
Essential Knowledge	1.A.4 Biological evolution is supported by scientific evidence from many disciplines, including mathematics.
Science Practice	4.2 The student can design a plan for collecting data to answer a particular scientific question.
Learning Objective	1.11 The student is able to design a plan to answer scientific questions regarding how organisms have changed over time using information from morphology, biochemistry, and geology.
Essential Knowledge	1.A.4 Biological evolution is supported by scientific evidence from many disciplines, including mathematics.
Science Practice	7.1 The student can connect phenomena and models across spatial and temporal scales.
Learning Objective	1.12 The student is able to connect scientific evidence from many scientific disciplines to support the modern concept of evolution.
Essential Knowledge	1.A.4 Biological evolution is supported by scientific evidence from many disciplines, including mathematics.
Science Practice	1.1 The student can create representations and models of natural or man-made phenomena and systems in the domain.
Science Practice	2.1 The student can justify the selection of a mathematical routine to solve problems.
Learning Objective	1.13 The student is able to construct and/or justify mathematical models, diagrams or simulations that represent processes of biological evolution.
Big Idea 1	The process of evolution drives the diversity and unity of life.
Enduring Understanding 1.B	Organisms are linked by lines of descent from common ancestry.
Essential Knowledge	1.B.1 Organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.

Science Practice	3.1 The student can pose scientific questions.
Learning Objective	1.14 The student is able to pose scientific questions that correctly identify essential properties of shared, core life processes that provide insight into the history of life on Earth.
Essential Knowledge	1.B.1 Organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Science Practice	7.2 The student can connect concepts in and across domain(s) to generalize or extrapolate in and/or across enduring understandings and/or big ideas.
Learning Objective	1.15 The student is able to describe specific examples of conserved core biological processes and features shared by all domains or within one domain of life, and how these shared, conserved core processes and features support the concept of common ancestry for all organisms.
Essential Knowledge	1.B.1 Organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Science Practice	6.1 The student can justify claims with evidence.
Learning Objective	1.16 The student is able to justify the scientific claim that organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Essential Knowledge	1.B.2 Phylogenetic trees and cladograms are graphical representations (models) of evolutionary history that can be tested.
Science Practice	3.1 The student can pose scientific questions.
Learning Objective	1.17 The student is able to pose scientific questions about a group of organisms whose relatedness is described by a phylogenetic tree or cladogram.
Essential Knowledge	1.B.2 Phylogenetic trees and cladograms are graphical representations (models) of evolutionary history that can be tested.
Science Practice	5.3 The student can evaluate the evidence provided by data sets in relation to a particular scientific question.
Learning Objective	1.18 The student is able to evaluate evidence provided by a data set in conjunction with a phylogenetic tree or simple cladogram to determine evolutionary history and speciation.
Essential Knowledge	1.B.2 Phylogenetic trees and cladograms are graphical representations (models) of evolutionary history that can be tested.
Science Practice	1.1 The student can create representations and models of natural or man-made phenomena and systems in the domain.
Science Practice	2.1 The student can justify the selection of a mathematical routine to solve problems.
Learning Objective	1.19 The student is able to create a phylogenetic tree or simple cladogram that correctly represents evolutionary history and speciation from a provided data set.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 1.15][APLO 1.16][APLO 1.18][APLO 1.17][APLO 1.19][APLO 1.26]

Two Options for Similarities

In general, organisms that share similar physical features and genomes tend to be more closely related than those that do not. Such features that overlap both morphologically (in form) and genetically are referred to as homologous structures; they stem from developmental similarities that are based on evolution. For example, the bones in the wings of bats and birds have homologous structures ([Figure 20.7](#)).

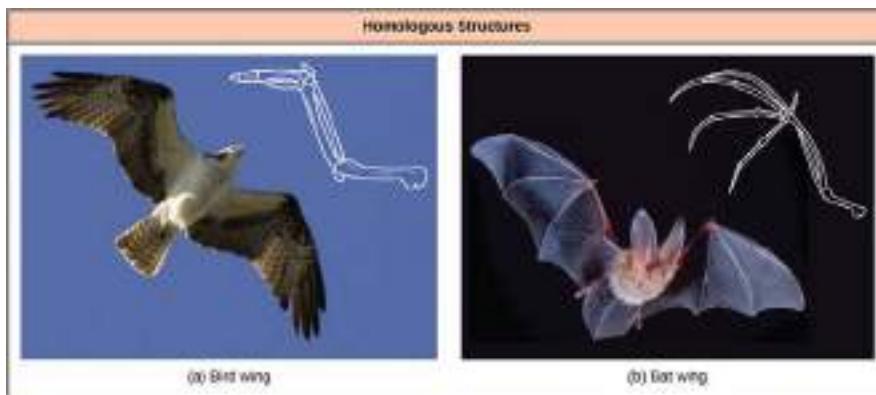

Figure 20.7 Bat and bird wings are homologous structures, indicating that bats and birds share a common evolutionary past. (credit a: modification of work by Steve Hillebrand, USFWS; credit b: modification of work by U.S. DOI BLM)

Notice it is not simply a single bone, but rather a grouping of several bones arranged in a similar way. The more complex the feature, the more likely any kind of overlap is due to a common evolutionary past. Imagine two people from different countries both inventing a car with all the same parts and in exactly the same arrangement without any previous or shared knowledge. That outcome would be highly improbable. However, if two people both invented a hammer, it would be reasonable to conclude that both could have the original idea without the help of the other. The same relationship between complexity and shared evolutionary history is true for homologous structures in organisms.

Misleading Appearances

Some organisms may be very closely related, even though a minor genetic change caused a major morphological difference to make them look quite different. Similarly, unrelated organisms may be distantly related, but appear very much alike. This usually happens because both organisms were in common adaptations that evolved within similar environmental conditions. When similar characteristics occur because of environmental constraints and not due to a close evolutionary relationship, it is called an **analogy** or homoplasy. For example, insects use wings to fly like bats and birds, but the wing structure and embryonic origin is completely different. These are called analogous structures (**Figure 20.8**).

Similar traits can be either homologous or analogous. Homologous structures share a similar embryonic origin; analogous organs have a similar function. For example, the bones in the front flipper of a whale are homologous to the bones in the human arm. These structures are not analogous. The wings of a butterfly and the wings of a bird are analogous but not homologous. Some structures are both analogous and homologous: the wings of a bird and the wings of a bat are both homologous and analogous. Scientists must determine which type of similarity a feature exhibits to decipher the phylogeny of the organisms being studied.

Figure 20.8 The (c) wing of a honeybee is similar in shape to a (b) bird wing and (a) bat wing, and it serves the same function. However, the honeybee wing is not composed of bones and has a distinctly different structure and embryonic origin. These wing types (insect versus bat and bird) illustrate an analogy—similar structures that do not share an evolutionary history. (credit a: modification of work by Steve Hillebrand, USFWS; credit b: modification of work by U.S. DOI BLM; credit c: modification of work by Jon Sullivan)

This [website](http://openstaxcollege.org/l/relationships) (<http://openstaxcollege.org/l/relationships>) has several examples to show how appearances can be misleading in understanding the phylogenetic relationships of organisms.

James Lake of the UCLA/NASA Astrobiology Institute presented new evidence regarding the evolution of eukaryotic cells. He hypothesized that eukaryotes developed from an endosymbiotic gene fusion between the two other domains of life. What kind of genetic evidence would best support this hypothesis?

- Their mitochondrial DNA resembles that of other eukaryotes.
- The chloroplasts of eukaryotes contain a double cell layer.
- All eukaryotic genes are identical to either Archaea or Bacteria.
- Some eukaryotic genes resemble those of Archaea, while some resemble those of Bacteria and some are unlike the genes of either domain.

Molecular Comparisons

With the advancement of DNA technology, the area of **molecular systematics**, which describes the use of information on the molecular level including DNA analysis, has blossomed. New computer programs not only confirm many earlier classified organisms, but also uncover previously made errors. As with physical characteristics, even the DNA sequence can be tricky to read in some cases. For some situations, two very closely related organisms can appear unrelated if a mutation

occurred that caused a shift in the genetic code. An insertion or deletion mutation would move each nucleotide base over one place, causing two similar codes to appear unrelated.

Sometimes two segments of DNA code in distantly related organisms randomly share a high percentage of bases in the same locations, causing these organisms to appear closely related when they are not. For both of these situations, computer technologies have been developed to help identify the actual relationships, and, ultimately, the coupled use of both morphologic and molecular information is more effective in determining phylogeny.

evolution CONNECTION

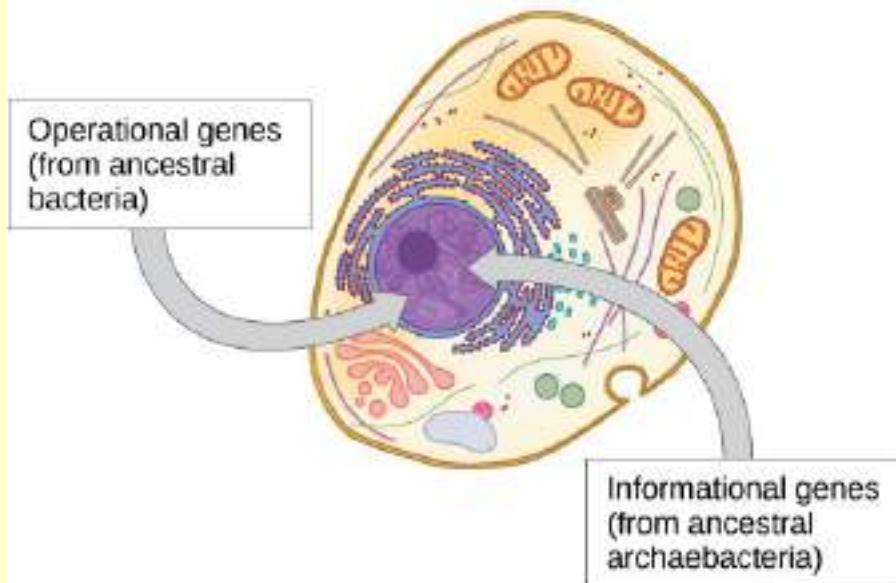

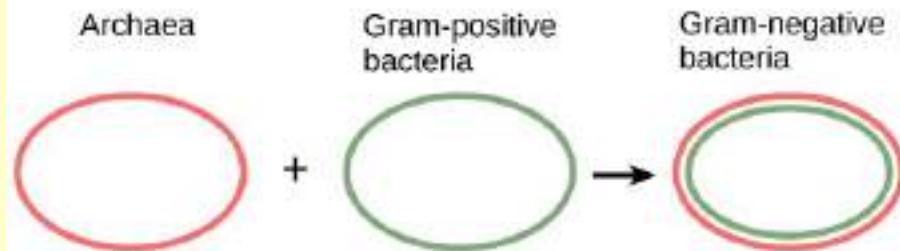

Why Does Phylogeny Matter?

Evolutionary biologists could list many reasons why understanding phylogeny is important to everyday life in human society. For botanists, phylogeny acts as a guide to discovering new plants that can be used to benefit people. Think of all the ways humans use plants—food, medicine, and clothing are a few examples. If a plant contains a compound that is effective in treating diseases, scientists might want to examine all of the relatives of that plant for other useful drugs.

A research team in China identified a segment of DNA thought to be common to some medicinal plants in the family Fabaceae (the legume family) and worked to identify which species had this segment (**Figure 20.9**). After testing plant species in this family, the team found a DNA marker (a known location on a chromosome that enabled them to identify the species) present. Then, using the DNA to uncover phylogenetic relationships, the team could identify whether a newly discovered plant was in this family and assess its potential medicinal properties.

Figure 20.9 *Dalbergia sissoo* (*D. sissoo*) is in the Fabaceae, or legume family. Scientists found that *D. sissoo* shares a DNA marker with species within the Fabaceae family that have antifungal properties. Subsequently, *D. sissoo* was shown to have fungicidal activity, supporting the idea that DNA markers can be used to screen for plants with potential medicinal properties.

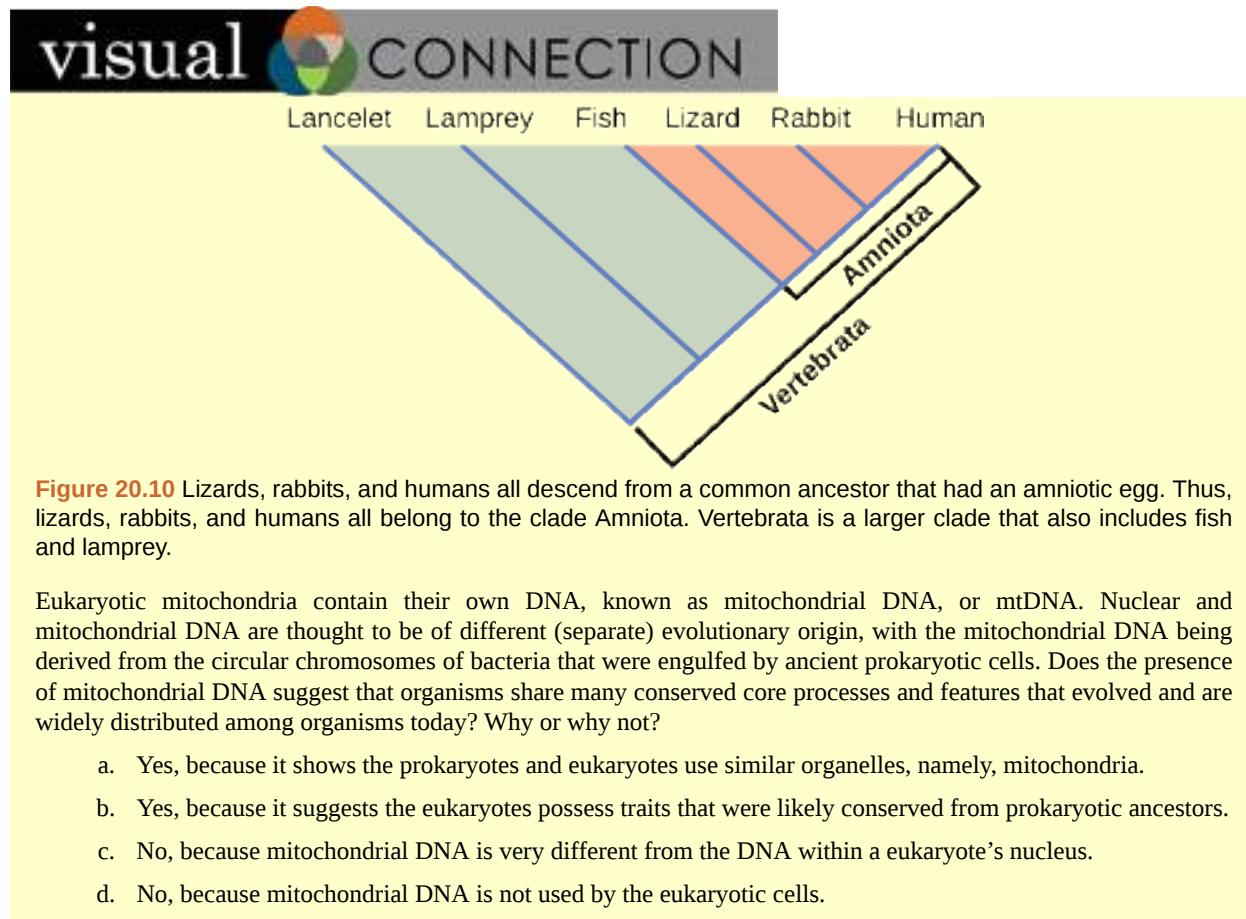

(a) Genome fusion by endosymbiosis**(b) Endosymbiotic formation of Gram-negative bacteria**

Part b of the figure shows a hypothetical model of the evolution of the cell membrane of gram-negative bacteria, which has a double membrane. If this hypothesis is true, what does it suggest about the evolution of mitochondria and chloroplasts in eukaryotic cells and why?

- Chloroplasts and mitochondria did not come about through endosymbiosis with gram-negative bacteria because these organelles have a single membrane.
- Chloroplasts and mitochondria likely evolved later in eukaryotic cells, as these organelles show no similarities to prokaryotes.
- Chloroplasts and mitochondria came about through endosymbiosis with Archaea and gram positive bacteria because these organelles have prokaryote-like DNA.
- Chloroplasts and mitochondria came about through endosymbiosis with gram-negative bacteria because these organelles have a double membrane.

Building Phylogenetic Trees

How do scientists construct phylogenetic trees? After the homologous and analogous traits are sorted, scientists often organize the homologous traits using a system called **cladistics**. This system sorts organisms into clades: groups of organisms that descended from a single ancestor. For example, in **Figure 20.10**, all of the organisms in the orange region evolved from a single ancestor that had amniotic eggs. Consequently, all of these organisms also have amniotic eggs and make a single clade, also called a **monophyletic group**. Clades must include all of the descendants from a branch point.

Clades can vary in size depending on which branch point is being referenced. The important factor is that all of the organisms in the clade or monophyletic group stem from a single point on the tree. This can be remembered because monophyletic breaks down into “mono,” meaning one, and “phyletic,” meaning evolutionary relationship. **Figure 20.11** shows various examples of clades. Notice how each clade comes from a single point, whereas the non-clade groups show branches that do not share a single point.

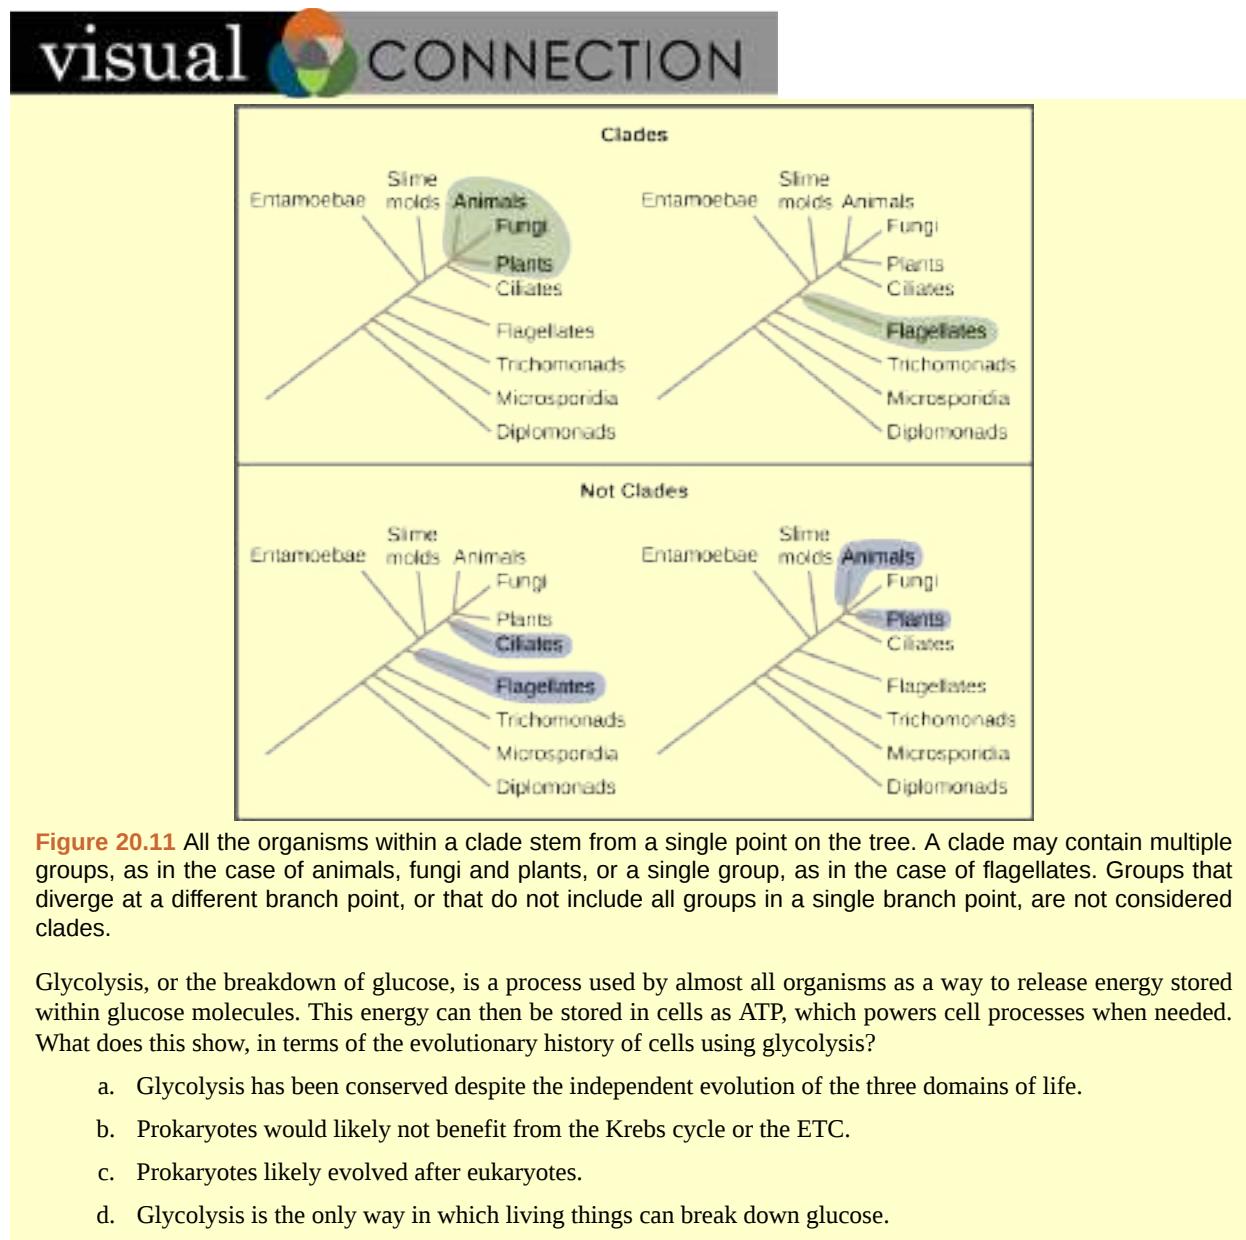

Figure 20.11 All the organisms within a clade stem from a single point on the tree. A clade may contain multiple groups, as in the case of animals, fungi and plants, or a single group, as in the case of flagellates. Groups that diverge at a different branch point, or that do not include all groups in a single branch point, are not considered clades.

Glycolysis, or the breakdown of glucose, is a process used by almost all organisms as a way to release energy stored within glucose molecules. This energy can then be stored in cells as ATP, which powers cell processes when needed. What does this show, in terms of the evolutionary history of cells using glycolysis?

- Glycolysis has been conserved despite the independent evolution of the three domains of life.
- Prokaryotes would likely not benefit from the Krebs cycle or the ETC.
- Prokaryotes likely evolved after eukaryotes.
- Glycolysis is the only way in which living things can break down glucose.

Shared Characteristics

Organisms evolve from common ancestors and then diversify. Scientists use the phrase “descent with modification” because even though related organisms have many of the same characteristics and genetic codes, changes occur. This pattern repeats over and over as one goes through the phylogenetic tree of life:

- A change in the genetic makeup of an organism leads to a new trait which becomes prevalent in the group.
- Many organisms descend from this point and have this trait.
- New variations continue to arise: some are adaptive and persist, leading to new traits.
- With new traits, a new branch point is determined (go back to step 1 and repeat).

If a characteristic is found in the ancestor of a group, it is considered a **shared ancestral character** because all of the organisms in the taxon or clade have that trait. The vertebrate in **Figure 20.10** is a shared ancestral character. Now consider the amniotic egg characteristic in the same figure. Only some of the organisms in **Figure 20.10** have this trait, and to those that do, it is called a **shared derived character** because this trait derived at some point but does not include all of the ancestors in the tree.

The tricky aspect to shared ancestral and shared derived characters is the fact that these terms are relative. The same trait can be considered one or the other depending on the particular diagram being used. Returning to **Figure 20.10**, note that the amniotic egg is a shared ancestral character for the Amniota clade, while having hair is a shared derived character for some organisms in this group. These terms help scientists distinguish between clades in the building of phylogenetic trees.

Choosing the Right Relationships

Imagine being the person responsible for organizing all of the items in a department store properly—an overwhelming task. Organizing the evolutionary relationships of all life on Earth proves much more difficult: scientists must span enormous blocks of time and work with information from long-extinct organisms. Trying to decipher the proper connections, especially given the presence of homologies and analogies, makes the task of building an accurate tree of life extraordinarily difficult. Add to that the advancement of DNA technology, which now provides large quantities of genetic sequences to be used and analyzed. Taxonomy is a subjective discipline: many organisms have more than one connection to each other, so each taxonomist will decide the order of connections.

To aid in the tremendous task of describing phylogenies accurately, scientists often use a concept called maximum parsimony, which means that events occurred in the simplest, most obvious way. For example, if a group of people entered a forest preserve to go hiking, based on the principle of maximum parsimony, one could predict that most of the people would hike on established trails rather than forge new ones.

For scientists deciphering evolutionary pathways, the same idea is used: the pathway of evolution probably includes the fewest major events that coincide with the evidence at hand. Starting with all of the homologous traits in a group of organisms, scientists look for the most obvious and simple order of evolutionary events that led to the occurrence of those traits.

Head to this **website** (<http://openstaxcollege.org/l/32species>) to learn how maximum parsimony is used to create phylogenetic trees.

What do phylogenetic relationships refer to?

- a. the similarities among organisms
- b. the differences among organisms
- c. the evolution of the shape, size and number of body parts
- d. the relative times in the past that species shared common ancestors

These tools and concepts are only a few of the strategies scientists use to tackle the task of revealing the evolutionary history of life on Earth. Recently, newer technologies have uncovered surprising discoveries with unexpected relationships, such as the fact that people seem to be more closely related to fungi than fungi are to plants. Sound unbelievable? As the information about DNA sequences grows, scientists will become closer to mapping the evolutionary history of all life on Earth.

Activity

Using a data set provided by your teacher or other sources, construct a phylogenetic tree or cladogram to reflect the evolutionary history among a group of organisms based on shared characteristics. Then share the phylogenetic tree or cladogram with peers for review and revision.

Lab Investigation

AP® Biology Investigative Labs: Inquiry-Based Approach, Investigation 3: Comparing DNA Sequences to Understand Evolutionary Relationships with BLAST. Students will learn to use a common tool, BLAST, to compare several genes from different organisms and then use this information to construct a cladogram to determine evolutionary relatedness among species. Then students will use BLAST to track a gene(s) of choice through several species. Bioinformatics has many applications, including understanding genetic disease.

Think About It

Why must scientists distinguish between homologous and analogous characteristics before building phylogenetic trees? Do more closely related organisms share homologous or analogous traits? Which type of trait is used to support convergent or divergent evolution?

20.3 | Perspectives on the Phylogenetic Tree

In this section, you will explore the following questions:

- What is horizontal gene transfer and its significance in constructing phylogenetic trees?
- How do prokaryotes and eukaryotes transfer genes horizontally?
- What are other models of phylogenetic relationships and how do they differ from the original phylogenetic tree concept?

Connection for AP® Courses

Newer technologies have uncovered surprising discoveries with unexpected relationships among organisms, such as the fact that humans seems to be more closely related to fungi than fungi are to plants. (Think about that the next time you see a mushroom). As the information about DNA sequences grows, scientists will become closer to mapping a more accurate evolutionary history of all life on Earth.

What makes phylogeny difficult, especially among prokaryotes, is the transfer of genes horizontally (**horizontal gene transfer**, or **HGT**) between unrelated species. Like mutations, HGT introduces genetic variation into the bacterial population. This passing of genes between species adds a layer of complexity to understanding relatedness.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Big Idea 1

The process of evolution drives the diversity and unity of life.

Enduring Understanding 1.B	Organisms are linked by lines of descent from common ancestry.
Essential Knowledge	1.B.1 Organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Science Practice	3.1 The student can pose scientific questions.
Learning Objective	1.14 The student is able to pose scientific questions that correctly identify essential properties of shared, core life processes that provide insight into the history of life on Earth.
Essential Knowledge	1.B.1 Organisms share many conserved core processes and features that evolved and are widely distributed among organisms today.
Science Practice	7.2 The student can connect concepts in and across domain(s) to generalize or extrapolate in and/or across enduring understandings and/or big ideas.
Learning Objective	1.15 The student is able to describe specific examples of conserved core biological processes and features shared by all domains or within one domain of life, and how these shared, conserved core processes and features support the concept of common ancestry for all organisms.
Big Idea 3	Living systems store, retrieve, transmit and respond to information essential to life processes.
Enduring Understanding 3.C	The processing of genetic information is imperfect and is a source of genetic variation.
Essential Knowledge	3.C.2 Biological systems have multiple processes that increase genetic variation.
Science Practice	6.2 The student can construct explanations of phenomena based on evidence produced through scientific practices.
Learning Objective	3.27 The student is able to construct an explanation of processes that increase variation within a population.

The concepts of phylogenetic modeling are constantly changing. It is one of the most dynamic fields of study in all of biology. Over the last several decades, new research has challenged scientists' ideas about how organisms are related. New models of these relationships have been proposed for consideration by the scientific community.

Many phylogenetic trees have been shown as models of the evolutionary relationship among species. Phylogenetic trees originated with Charles Darwin, who sketched the first phylogenetic tree in 1837 ([Figure 20.12a](#)), which served as a pattern for subsequent studies for more than a century. The concept of a phylogenetic tree with a single trunk representing a common ancestor, with the branches representing the divergence of species from this ancestor, fits well with the structure of many common trees, such as the oak ([Figure 20.12b](#)). However, evidence from modern DNA sequence analysis and newly developed computer algorithms has caused skepticism about the validity of the standard tree model in the scientific community.

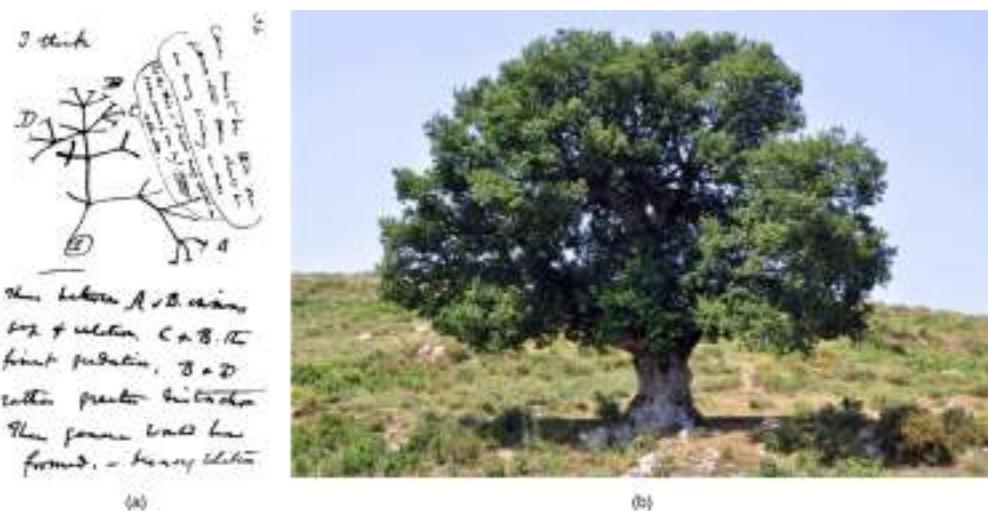

Figure 20.12 The (a) concept of the “tree of life” goes back to an 1837 sketch by Charles Darwin. Like an (b) oak tree, the “tree of life” has a single trunk and many branches. (credit b: modification of work by "Amada44"/Wikimedia Commons)

Limitations to the Classic Model

Classical thinking about prokaryotic evolution, included in the classic tree model, is that species evolve clonally. That is, they produce offspring themselves with only random mutations causing the descent into the variety of modern-day and extinct species known to science. This view is somewhat complicated in eukaryotes that reproduce sexually, but the laws of Mendelian genetics explain the variation in offspring, again, to be a result of a mutation within the species. The concept of genes being transferred between unrelated species was not considered as a possibility until relatively recently. Horizontal gene transfer (HGT), also known as lateral gene transfer, is the transfer of genes between unrelated species. HGT has been shown to be an ever-present phenomenon, with many evolutionists postulating a major role for this process in evolution, thus complicating the simple tree model. Genes have been shown to be passed between species which are only distantly related using standard phylogeny, thus adding a layer of complexity to the understanding of phylogenetic relationships.

The various ways that HGT occurs in prokaryotes is important to understanding phylogenies. Although at present HGT is not viewed as important to eukaryotic evolution, HGT does occur in this domain as well. Finally, as an example of the ultimate gene transfer, theories of genome fusion between symbiotic or endosymbiotic organisms have been proposed to explain an event of great importance—the evolution of the first eukaryotic cell, without which humans could not have come into existence.

Horizontal Gene Transfer

Horizontal gene transfer (HGT) is the introduction of genetic material from one species to another species by mechanisms other than the vertical transmission from parent(s) to offspring. These transfers allow even distantly related species to share genes, influencing their phenotypes. It is thought that HGT is more prevalent in prokaryotes, but that only about 2% of the prokaryotic genome may be transferred by this process. Some researchers believe such estimates are premature: the actual importance of HGT to evolutionary processes must be viewed as a work in progress. As the phenomenon is investigated more thoroughly, it may be revealed to be more common. Many scientists believe that HGT and mutation appear to be (especially in prokaryotes) a significant source of genetic variation, which is the raw material for the process of natural selection. These transfers may occur between any two species that share an intimate relationship (**Table 20.1**).

Summary of Mechanisms of Prokaryotic and Eukaryotic HGT

Mechanism	Mode of Transmission	Example
Prokaryotes	transformation	DNA uptake
	transduction	bacteriophage (virus)
	conjugation	pilus

Table 20.1

Summary of Mechanisms of Prokaryotic and Eukaryotic HGT

	Mechanism	Mode of Transmission	Example
Eukaryotes	gene transfer agents	phage-like particles	purple non-sulfur bacteria
	from food organisms	unknown	aphid
	jumping genes	transposons	rice and millet plants
	epiphytes/parasites	unknown	yew tree fungi
	from viral infections		

Table 20.1

HGT in Prokaryotes

The mechanism of HGT has been shown to be quite common in the prokaryotic domains of Bacteria and Archaea, significantly changing the way their evolution is viewed. The majority of evolutionary models, such as in the Endosymbiont Theory, propose that eukaryotes descended from multiple prokaryotes, which makes HGT all the more important to understanding the phylogenetic relationships of all extant and extinct species.

The fact that genes are transferred among common bacteria is well known to microbiology students. These gene transfers between species are the major mechanism whereby bacteria acquire resistance to antibiotics. Classically, this type of transfer has been thought to occur by three different mechanisms:

1. Transformation: naked DNA is taken up by a bacteria
2. Transduction: genes are transferred using a virus
3. Conjugation: the use a hollow tube called a pilus to transfer genes between organisms

More recently, a fourth mechanism of gene transfer between prokaryotes has been discovered. Small, virus-like particles called **gene transfer agents (GTAs)** transfer random genomic segments from one species of prokaryote to another. GTAs have been shown to be responsible for genetic changes, sometimes at a very high frequency compared to other evolutionary processes. The first GTA was characterized in 1974 using purple, non-sulfur bacteria. These GTAs, which are thought to be bacteriophages that lost the ability to reproduce on their own, carry random pieces of DNA from one organism to another. The ability of GTAs to act with high frequency has been demonstrated in controlled studies using marine bacteria. Gene transfer events in marine prokaryotes, either by GTAs or by viruses, have been estimated to be as high as 10^{13} per year in the Mediterranean Sea alone. GTAs and viruses are thought to be efficient HGT vehicles with a major impact on prokaryotic evolution.

As a consequence of this modern DNA analysis, the idea that eukaryotes evolved directly from Archaea has fallen out of favor. While eukaryotes share many features that are absent in bacteria, such as the TATA box (found in the promoter region of many genes), the discovery that some eukaryotic genes were more homologous with bacterial DNA than Archaea DNA made this idea less tenable. Furthermore, the fusion of genomes from Archaea and Bacteria by endosymbiosis has been proposed as the ultimate event in eukaryotic evolution.

HGT in Eukaryotes

Although it is easy to see how prokaryotes exchange genetic material by HGT, it was initially thought that this process was absent in eukaryotes. After all, prokaryotes are but single cells exposed directly to their environment, whereas the sex cells of multicellular organisms are usually sequestered in protected parts of the body. It follows from this idea that the gene transfers between multicellular eukaryotes should be more difficult. Indeed, it is thought that this process is rarer in eukaryotes and has a much smaller evolutionary impact than in prokaryotes. In spite of this fact, HGT between distantly related organisms has been demonstrated in several eukaryotic species, and it is possible that more examples will be discovered in the future.

In plants, gene transfer has been observed in species that cannot cross-pollinate by normal means. Transposons or “jumping genes” have been shown to transfer between rice and millet plant species. Furthermore, fungal species feeding on yew trees, from which the anti-cancer drug paclitaxel is derived from the bark, have acquired the ability to make paclitaxel themselves, a clear example of gene transfer.

In animals, a particularly interesting example of HGT occurs within the aphid species (**Figure 20.13**). Aphids are insects that vary in color based on carotenoid content. Carotenoids are pigments made by a variety of plants, fungi, and microbes, and they serve a variety of functions in animals, who obtain these chemicals from their food. Humans require carotenoids

to synthesize vitamin A, and we obtain them by eating orange fruits and vegetables: carrots, apricots, mangoes, and sweet potatoes. On the other hand, aphids have acquired the ability to make the carotenoids on their own. According to DNA analysis, this ability is due to the transfer of fungal genes into the insect by HGT, presumably as the insect consumed fungi for food. A carotenoid enzyme called a desaturase is responsible for the red coloration seen in certain aphids, and it has been further shown that when this gene is inactivated by mutation, the aphids revert back to their more common green color ([Figure 20.13](#)).

Figure 20.13 (a) Red aphids get their color from red carotenoid pigment. Genes necessary to make this pigment are present in certain fungi, and scientists speculate that aphids acquired these genes through HGT after consuming fungi for food. If genes for making carotenoids are inactivated by mutation, the aphids revert back to (b) their green color. Red coloration makes the aphids a lot more conspicuous to predators, but evidence suggests that red aphids are more resistant to insecticides than green ones. Thus, red aphids may be more fit to survive in some environments than green ones. (credit a: modification of work by Benny Mazur; credit b: modification of work by Mick Talbot)

everyday CONNECTION for AP[®] Courses

Barbara McClintock (1902–1992) discovered transposons while working on maize genetics.

Figure 20.14

What does the Eukaryote-first hypothesis suggest?

- that mitochondria were first established in a prokaryotic host which acquired a nucleus to become the first eukaryotic cell
- that the nucleus evolved in prokaryotes first followed by fusion of the new eukaryote with bacteria that became mitochondria
- that prokaryotes actually evolved from eukaryotes by losing genes and complexity
- that eukaryotes developed Golgi before mitochondria

Genome Fusion and the Evolution of Eukaryotes

Scientists believe the ultimate in HGT occurs through **genome fusion** between different species of prokaryotes when two symbiotic organisms become endosymbiotic. This occurs when one species is taken inside the cytoplasm of another species, which ultimately results in a genome consisting of genes from both the endosymbiont and the host. This mechanism is an aspect of the Endosymbiont Theory, which is accepted by a majority of biologists as the mechanism whereby eukaryotic cells obtained their mitochondria and chloroplasts. However, the role of endosymbiosis in the development of the nucleus is more controversial. Nuclear and mitochondrial DNA are thought to be of different (separate) evolutionary origin, with the mitochondrial DNA being derived from the circular genomes of bacteria that were engulfed by ancient prokaryotic cells. Mitochondrial DNA can be regarded as the smallest chromosome. Interestingly enough, mitochondrial DNA is inherited only from the mother. The mitochondrial DNA degrades in sperm when the sperm degrades in the fertilized egg or in other instances when the mitochondria located in the flagellum of the sperm fails to enter the egg.

Within the past decade, the process of genome fusion by endosymbiosis has been proposed by James Lake of the UCLA/NASA Astrobiology Institute to be responsible for the evolution of the first eukaryotic cells (**Figure 20.15a**). Using DNA analysis and a new mathematical algorithm called conditioned reconstruction (CR), his laboratory proposed that eukaryotic cells developed from an endosymbiotic gene fusion between two species, one an Archaea and the other a Bacteria. As mentioned, some eukaryotic genes resemble those of Archaea, whereas others resemble those from Bacteria. An endosymbiotic fusion event, such as Lake has proposed, would clearly explain this observation. On the other hand, this work is new and the CR algorithm is relatively unsubstantiated, which causes many scientists to resist this hypothesis.

More recent work by Lake (**Figure 20.15b**) proposes that gram-negative bacteria, which are unique within their domain

in that they contain two lipid bilayer membranes, indeed resulted from an endosymbiotic fusion of archaeal and bacterial species. The double membrane would be a direct result of the endosymbiosis, with the endosymbiont picking up the second membrane from the host as it was internalized. This mechanism has also been used to explain the double membranes found in mitochondria and chloroplasts. Lake's work is not without skepticism, and the ideas are still debated within the biological science community. In addition to Lake's hypothesis, there are several other competing theories as to the origin of eukaryotes. How did the eukaryotic nucleus evolve? One theory is that the prokaryotic cells produced an additional membrane that surrounded the bacterial chromosome. Some bacteria have the DNA enclosed by two membranes; however, there is no evidence of a nucleolus or nuclear pores. Other proteobacteria also have membrane-bound chromosomes. If the eukaryotic nucleus evolved this way, we would expect one of the two types of prokaryotes to be more closely related to eukaryotes.

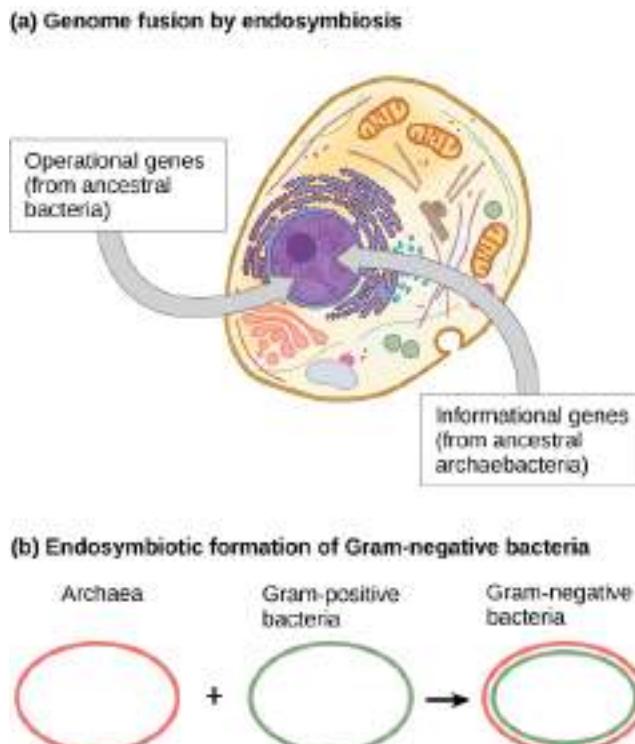

Figure 20.15 The theory that mitochondria and chloroplasts are endosymbiotic in origin is now widely accepted. More controversial is the proposal that (a) the eukaryotic nucleus resulted from the fusion of archaeal and bacterial genomes, and that (b) Gram-negative bacteria, which have two membranes, resulted from the fusion of Archaea and Gram-positive bacteria, each of which has a single membrane.

The **nucleus-first** hypothesis proposes that the nucleus evolved in prokaryotes first (Figure 20.16a), followed by a later fusion of the new eukaryote with bacteria that became mitochondria. The **mitochondria-first** hypothesis proposes that mitochondria were first established in a prokaryotic host (Figure 20.16b), which subsequently acquired a nucleus, by fusion or other mechanisms, to become the first eukaryotic cell. Most interestingly, the **eukaryote-first** hypothesis proposes that prokaryotes actually evolved from eukaryotes by losing genes and complexity (Figure 20.16c). All of these hypotheses are testable. Only time and more experimentation will determine which hypothesis is best supported by data.

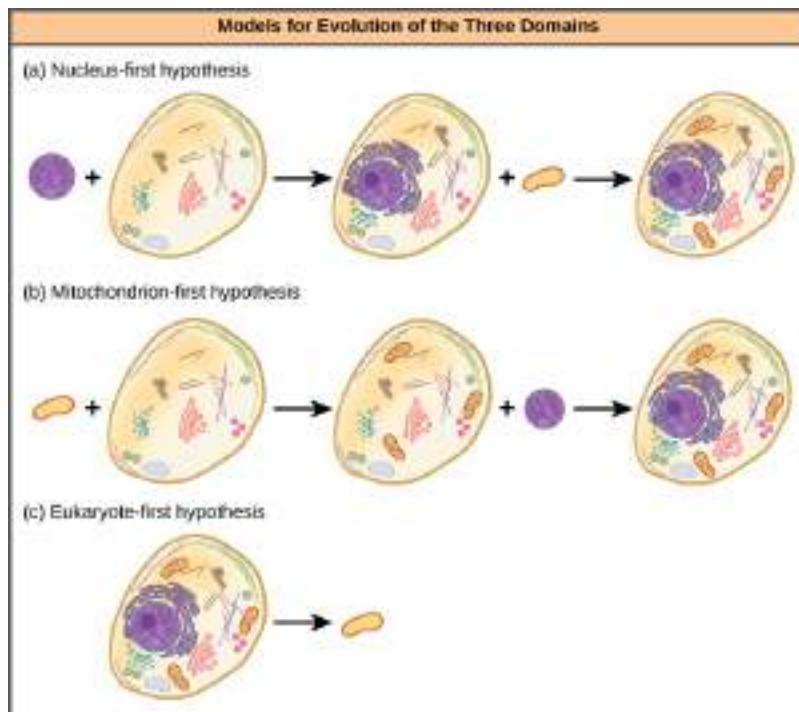

Figure 20.16 Three alternate hypotheses of eukaryotic and prokaryotic evolution are (a) the nucleus-first hypothesis, (b) the mitochondrion-first hypothesis, and (c) the eukaryote-first hypothesis.

Web and Network Models

The recognition of the importance of HGT, especially in the evolution of prokaryotes, has caused some to propose abandoning the classic “tree of life” model. In 1999, W. Ford Doolittle proposed a phylogenetic model that resembles a web or a network more than a tree. The hypothesis is that eukaryotes evolved not from a single prokaryotic ancestor, but from a pool of many species that were sharing genes by HGT mechanisms. As shown in **Figure 20.17a**, some individual prokaryotes were responsible for transferring the bacteria that caused mitochondrial development to the new eukaryotes, whereas other species transferred the bacteria that gave rise to chloroplasts. This model is often called the “**web of life**.” In an effort to save the tree analogy, some have proposed using the *Ficus* tree (**Figure 20.17b**) with its multiple trunks as a phylogenetic to represent a diminished evolutionary role for HGT.

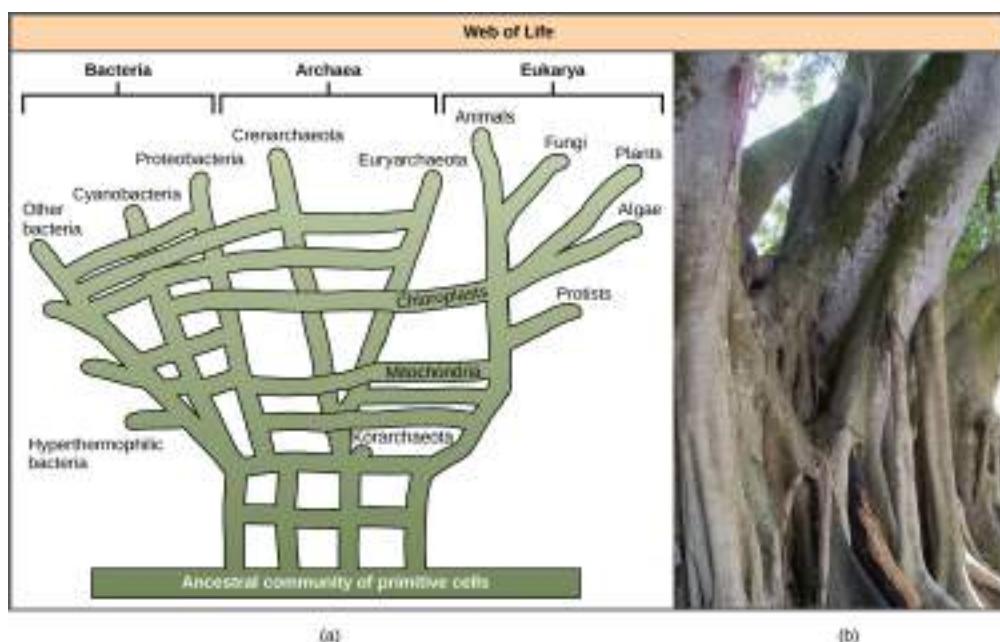

Figure 20.17 In the (a) phylogenetic model proposed by W. Ford Doolittle, the “tree of life” arose from a community of ancestral cells, has multiple trunks, and has connections between branches where horizontal gene transfer has occurred. Visually, this concept is better represented by (b) the multi-trunked *Ficus* than by the single trunk of the oak similar to the tree drawn by Darwin [Figure 20.12](#). (credit b: modification of work by “psyberartist”/Flickr)

Ring of Life Models

Others have proposed abandoning any tree-like model of phylogeny in favor of a ring structure, the so-called “**ring of life**” ([Figure 20.18](#)); a phylogenetic model where all three domains of life evolved from a pool of primitive prokaryotes. Lake, again using the conditioned reconstruction algorithm, proposes a ring-like model in which species of all three domains—Archaea, Bacteria, and Eukarya—evolved from a single pool of gene-swapping prokaryotes. His laboratory proposes that this structure is the best fit for data from extensive DNA analyses performed in his laboratory, and that the ring model is the only one that adequately takes HGT and genomic fusion into account. However, other phylogeneticists remain highly skeptical of this model.

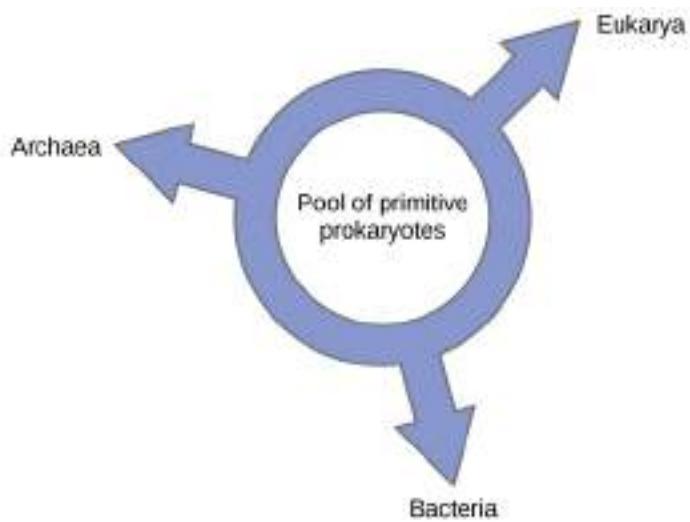

Figure 20.18 According to the “ring of life” phylogenetic model, the three domains of life evolved from a pool of primitive prokaryotes.

In summary, the “tree of life” model proposed by Darwin must be modified to include HGT. Does this mean abandoning the tree model completely? Even Lake argues that all attempts should be made to discover some modification of the tree model to allow it to accurately fit his data, and only the inability to do so will sway people toward his ring proposal.

This doesn't mean a tree, web, or a ring will correlate completely to an accurate description of phylogenetic relationships of life. A consequence of the new thinking about phylogenetic models is the idea that Darwin's original conception of the phylogenetic tree is too simple, but made sense based on what was known at the time. However, the search for a more useful model moves on: each model serving as hypotheses to be tested with the possibility of developing new models. This is how science advances. These models are used as visualizations to help construct hypothetical evolutionary relationships and understand the massive amount of data being analyzed.

KEY TERMS

analogy (also, homoplasy) characteristic that is similar between organisms by convergent evolution, not due to the same evolutionary path

basal taxon branch on a phylogenetic tree that has not diverged significantly from the root ancestor

binomial nomenclature system of two-part scientific names for an organism, which includes genus and species names

branch point node on a phylogenetic tree where a single lineage splits into distinct new ones

cladistics system used to organize homologous traits to describe phylogenies

cladograms visual representations of evolutionary relationships between organisms

class division of phylum in the taxonomic classification system

eukaryote-first hypothesis proposal that prokaryotes evolved from eukaryotes

family division of order in the taxonomic classification system

gene transfer agent (GTA) bacteriophage-like particle that transfers random genomic segments from one species of prokaryote to another

genome fusion fusion of two prokaryotic genomes, presumably by endosymbiosis

genus division of family in the taxonomic classification system; the first part of the binomial scientific name

horizontal gene transfer (HGT) (also, lateral gene transfer) transfer of genes between unrelated species

kingdom division of domain in the taxonomic classification system

maximum parsimony applying the simplest, most obvious way with the least number of steps

mitochondria-first hypothesis proposal that prokaryotes acquired a mitochondrion first, followed by nuclear development

molecular systematics technique using molecular evidence to identify phylogenetic relationships

monophyletic group (also, clade) organisms that share a single ancestor

nucleus-first hypothesis proposal that prokaryotes acquired a nucleus first, and then the mitochondrion

order division of class in the taxonomic classification system

parsimony the simplest, most straightforward way of constructing phylogenetic and evolutionary relationships between organisms

phylogenetic tree diagram used to reflect the evolutionary relationships among organisms or groups of organisms

phylogeny evolutionary history and relationship of an organism or group of organisms

phylum (plural: phyla) division of kingdom in the taxonomic classification system

polytomy branch on a phylogenetic tree with more than two groups or taxa

ring of life phylogenetic model where all three domains of life evolved from a pool of primitive prokaryotes

rooted single ancestral lineage on a phylogenetic tree to which all organisms represented in the diagram relate

shared ancestral character describes a characteristic on a phylogenetic tree that is shared by all organisms on the tree

shared derived character describes a characteristic on a phylogenetic tree that is shared only by a certain clade of

organisms

sister taxa two lineages that diverged from the same branch point

systematics field of organizing and classifying organisms based on evolutionary relationships

taxon (plural: taxa) single level in the taxonomic classification system

taxonomic classification system hierarchical system of classifying organisms, including the classification of domain, kingdom, phylum, class, order, family, genus, and species

taxonomy science of classifying organisms

web of life phylogenetic model that attempts to incorporate the effects of horizontal gene transfer on evolution

CHAPTER SUMMARY

20.1 Organizing Life on Earth

Scientists continually gain new information that helps understand the evolutionary history of life on Earth. Each group of organisms went through its own evolutionary journey, called its phylogeny. Each organism shares relatedness with others, and based on morphologic and genetic evidence, scientists attempt to map the evolutionary pathways of all life on Earth. Historically, organisms were organized into a taxonomic classification system. However, today many scientists build phylogenetic trees to illustrate evolutionary relationships.

20.2 Determining Evolutionary Relationships

To build phylogenetic trees, scientists must collect accurate information that allows them to make evolutionary connections between organisms. Using morphologic and molecular data, scientists work to identify homologous characteristics and genes. Similarities between organisms can stem either from shared evolutionary history (homologies) or from separate evolutionary paths (analogies). Newer technologies can be used to help distinguish homologies from analogies. After homologous information is identified, scientists use cladistics to organize these events as a means to determine an evolutionary timeline. Scientists apply the concept of maximum parsimony, which states that the order of events probably occurred in the most obvious and simple way with the least amount of steps. For evolutionary events, this would be the path with the least number of major divergences that correlate with the evidence.

20.3 Perspectives on the Phylogenetic Tree

The phylogenetic tree, first used by Darwin, is the classic “tree of life” model describing phylogenetic relationships among species, and the most common model used today. New ideas about HGT and genome fusion have caused some to suggest revising the model to resemble webs or rings.

REVIEW QUESTIONS

1. Who devised a commonly used classification system?
 - a. Carl Linnaeus
 - b. Darwin
 - c. Plato
 - d. Aristotle
 2. Which of the following uses a hierarchical model to classify organisms?
 - a. analogy
 - b. taxonomic classification system
 - c. Order
 - d. systematics
 3. Correctly list the hierarchy of taxonomy.
 4. Which of category, below the level of Kingdom, would have the next largest number of organisms?
- a. Kingdom, Domain, Phylum, Order, Class, Family, Genus, species
b. Domain, Kingdom, Class, Phylum, Order, Family, Genus, species
c. Domain, Kingdom, Phylum, Class, Order, Family, Genus, species
d. Domain, Kingdom, Class, Phylum, Order, Family, Genus, species

- a. Order
b. Phylum
c. Family
d. Class
- 5.** How is systematics related to phylogeny?
- Systematics provides guidelines that scientists use to describe the relationships of organisms.
 - Scientists use systematics programs to put together the phylogeny of an organism.
 - In systematics, scientists use combined data based on evolutionary relationships from many sources to put together the phylogeny of an organism.
 - Systematics is a process used to put together the phylogeny of an organism.
- 6.** Which of the following is the best explanation of what systematists do?
- Scientists in the field of systematics organize organisms by characteristics.
 - Scientists in the field of systematics provide information on how organisms are similar or different.
 - Scientists in the field of systematics contribute to building, updating, and maintaining the “tree of life.”
 - Scientists in the field of systematics collect data from fossils.
- 7.** What is the purpose of a phylogenetic tree?
- to organize and name organisms into specific categories
 - The taxonomy is used to organize and name organisms into specific categories.
 - to show the evolutionary pathways and connections among organisms
 - to show geographic or behavioral factors
- 8.** What does the term “rooted” mean on a phylogenetic tree diagram?
- relationships among species do not show
 - all organisms represented in the diagram relate to a single ancestral lineage
 - a single lineage evolved into a distinct new one
 - A lineage evolved early from the root and remains unbranched.
- 9.** Phylogeny is important to everyday life in human society. How did the research team in China use phylogeny as a guide to discover new plants that can be used to benefit people?
- a. The research team used DNA to uncover phylogenetic relationships in the legume family, and they found a compound in the plant that is effective in treating cancer.
b. The research team used DNA to uncover phylogenetic relationships in the legume family, and then they identified a newly discovered plant as *Dalbergia sissoo*.
c. The research team used DNA to uncover phylogenetic relationships in the legume family, and they found a DNA marker that can be used to screen for plants with potential medicinal properties.
d. The research team searched all the relatives of the newly discovered plant *Dalbergia sissoo* to find antifungal properties.
- 10.** Which animals in the figure belong to a clade that includes animals with hair? Which evolved first, hair or the amniotic egg?
-
- ```

graph TD
 Root --- Lancelet
 Root --- Lamprey
 Lancelet --- Fish
 Lamprey --- Fish
 Fish --- Lizard
 Lizard --- Rabbit
 Lizard --- Human
 Rabbit --- Human

```
- 11.** What is the largest clade in the preceding diagram?
- Animals, Fungi, and Plants
  - Fungi
  - Diplomonads
  - Flagellates
- 12.** Why is it important for scientists to distinguish between homologous and analogous characteristics before building phylogenetic trees?

- a. Phylogenetic trees are based on evolutionary connections, so scientists can use the analogous characteristics to build the phylogenetic trees.
- b. Phylogenetic trees are based on evolutionary connections, so scientists can use the homologous characteristics to build the phylogenetic trees.
- c. Phylogenetic trees are based on similar functions, so scientists can use the homologous characteristics to build the phylogenetic trees.
- d. Phylogenetic trees are based on similar functions, so scientists can use the homologous characteristics to build the phylogenetic trees.

**13. Describe an analogous structure.**

- a. A penguin and a seagull both have wings. The penguin uses wings to swim while the seagull uses wings to fly.
- b. Lizards and whales have similar skeleton structures, but they have a different habitat and lifestyle.
- c. Birds and butterflies have wings with similar characteristics for flight even though their wings do not share an evolutionary relationship.
- d. The bone structure in leg of a cat is very similar to the bone structure in the arm of a human, but the functions of the limbs are very different.

**14. What is the ring of life?**

- a. a phylogenetic model where all three domains of life evolved from a pool of primitive prokaryotes
- b. an evolutionary history and relationship of an organism or group of organisms
- c. a phylogenetic model that attempts to incorporate the effects of horizontal gene transfer on evolution
- d. a field of organizing and classifying organisms based on evolutionary relationships

**15. Some individual prokaryotes were responsible for transferring the bacteria that caused mitochondrial development to the new eukaryotes, whereas other species transferred the bacteria that gave rise to chloroplasts. This statement best describes which model?**

- a. ring of life
- b. tree of life
- c. branches of life
- d. web of life

**16. Explain why the classic tree model needs to be revised.**

- a. The model is unable to incorporate DNA evidence.
- b. The model is erroneously based on many analogous traits, which have no basis in evolutionary relationships.
- c. The model cannot be experimentally verified.
- d. The model does not consider the possibility that genes could be transferred between unrelated species.

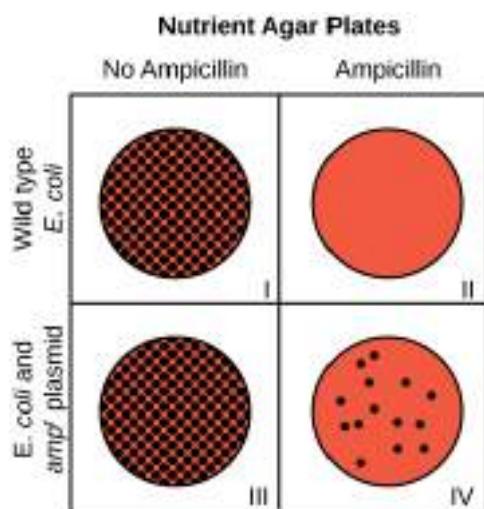

**17. Compare three different ways that eukaryotic cells may have evolved.**

- a. Some hypotheses propose that mitochondria were acquired first. Others propose that the nucleus evolved first. Still others hypothesize that prokaryotes descended from eukaryotes by the loss of genes and complexity.
- b. Some hypotheses propose that eukaryotic cells are a combination of bacterial and archaeal cells. Others propose that eukaryotic cells are a combination of bacterial and fungal cells. Still others hypothesize that eukaryotic and prokaryotic cells developed independently.
- c. Some hypotheses propose that mitochondria developed from bacterial cells. Others propose that they developed from archaeal cells. Still others hypothesize that bacteria developed from mitochondria that had been released from eukaryotic cells.
- d. Some hypotheses propose that eukaryotic cells developed from gram-negative bacteria. Others propose that they developed from gram-positive bacteria. Still others hypothesize that both gram-positive and gram-negative bacteria contributed to the eukaryotic genome through horizontal gene transfer.

**18. Explain the ring of life model.**

- a. The ring of life model is a phylogenetic model where the three domains of life started as distinct groups that could swap genes horizontally with each other in all directions.
- b. The ring of life model is a phylogenetic model where all three domains of life are said to have developed from a pool of primitive prokaryotes.
- c. The ring of life model is a phylogenetic model where bacterial and archaeal cells fused to form eukaryotic cells.
- d. The ring of life model is a phylogenetic model where there is only a single domain of life due to modern DNA analysis.

**19.**

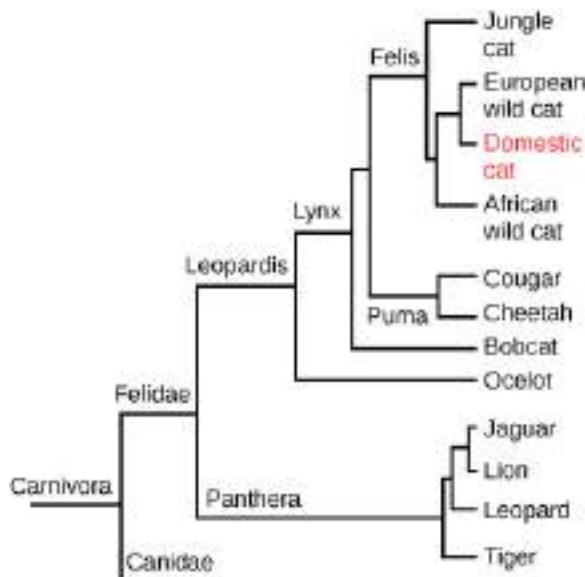

In a transformation experiment, a sample of *E. coli* bacteria was mixed with a plasmid containing the gene for resistance to the antibiotic ampicillin (*amp<sup>r</sup>*). Plasmid was not added to the second sample. Samples were plated on nutrient agar plates, some of which were supplemented with the antibiotic ampicillin. The results of *E. coli* growth are summarized below. The shaded area represents extensive growth of bacteria; dots represent individual colonies of bacteria. Plates that have only ampicillin resistant bacteria include which of the following?

- a. I only
- b. III only
- c. IV only
- d. I and II

## CRITICAL THINKING QUESTIONS

20. Describe how organisms are classified in the taxonomic classification system.
- a. The taxonomic classification system uses a hierarchical model to organize living organisms. At each sublevel, the organisms are more similar.
  - b. The taxonomic classification system uses a hierarchical model to organize living organisms. At each sublevel, the number of organisms increases.
  - c. The categories in the taxonomic classification system are organized from smaller, more specific categories to larger categories.
  - d. In the hierarchical model for the taxonomic classification system, from the point of origin, the groups become less specific.
21. What is the correct way to format a two-word scientific name?
- a. Italicize both words. Both words are lower case.
  - b. Italicize both words. The first word should be capitalized. The second word should be lower case.
  - c. Italicize both words. Capitalize both words.
  - d. Underline both words. Capitalize both words.
22. Some organisms that appear very closely related may not actually be closely related. Why is this?
23. How does a phylogenetic tree relate to the passing of time?
- a. A phylogenetic tree relates to the passing of time because species branch off from each other at regular time intervals.
  - b. A phylogenetic tree is not related to the passing of time because speciation is based on geographic changes.
  - c. The phylogenetic tree only shows the order in which things took place.
  - d. A phylogenetic tree relates to the passing of time when the diagram also shows how long ago the divergence from the common ancestor occurred.
24. Judeo-Christian religious texts explain that the Earth and all the organisms on Earth were created in seven days. Why is this not a valid scientific hypothesis?
25. Scientists use the cladistics system to organize what?
- a. homologous traits
  - b. homoplasies
  - c. analogous traits
  - d. monophyletic groups
26. Describe how a clade relates to monophyletic group.

- Clades vary in size depending on the number of branches.
  - All the organisms within a clade stem from a single point on the phylogenetic tree.
  - A clade shows branches that do not share a single point.
  - A clade shows groups that diverge at a different branch point.
27. Scientists apply the concept of maximum parsimony to do what?
- describe phylogenies accurately
  - eliminate analogous traits
  - identify mutations to DNA codes
  - locate homoplasies
28. You discover a new species of animal in the rainforest. What characteristics could you use to distinguish this organism from the other organisms in the same clade based on **Figure 20.11**?
29. Based on the phylogenetic tree below, is the Jungle cat likely closer related to a tiger or a cougar? Why?

**Figure 20.19**

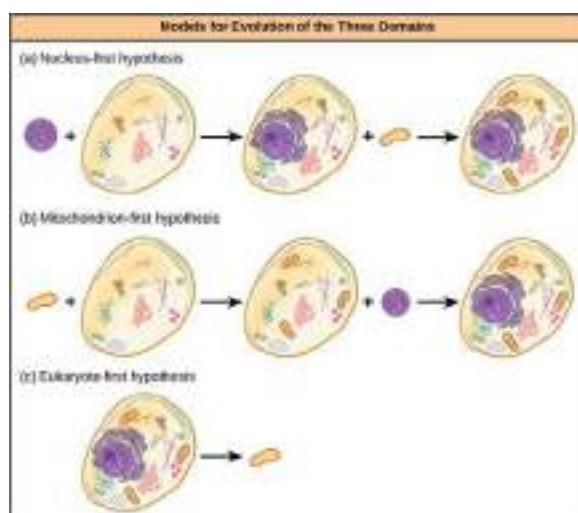

30. Two cultures of bacteria are separated by a filter that blocks the movement of cells but allows free exchange of anything smaller than a bacterial cell. On one side of the filter, a sample of penicillin resistant cells in culture broth is added, on the second side of the tube, a culture of penicillin sensitive cells in culture is added. After 24 hours, resistant cells appear on the side with the cells sensitive to penicillin. Which three genetic mechanisms can account for appearance of the penicillin resistant cells?

- transformation, transduction, and conjugation
- transformation, transduction, and mutation
- transformation, conjugation, and mutation
- transduction, conjugation, and mutation

## TEST PREP FOR AP® COURSES

31. What evolutionary question is better addressed by the fig-shaped evolutionary tree in **Figure 20.17**, as opposed to the more typical, single-trunk phylogenetic tree in **Figure 20.2**?

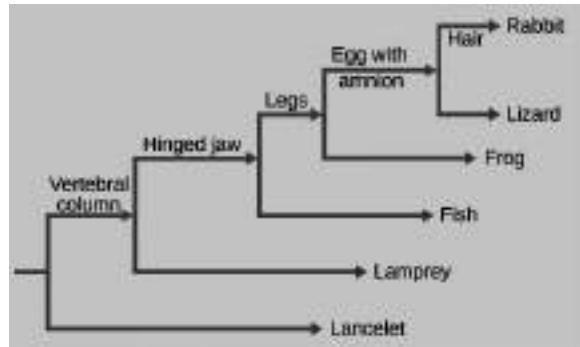

- What was the single organism from which all other forms of life on Earth arose?
  - Did animals evolve from fungi?
  - In which species of eukaryote did chloroplasts first appear?
  - Were chloroplasts and mitochondria transferred to eukaryotic cells through horizontal gene transfer?
- 32.

Which question, relating to the endosymbiotic hypothesis and the evolution of eukaryotes, is not answered by the eukaryote-first hypothesis, based on the figures?

- Which evolved first, the nucleus or prokaryotes?
- Which evolved first, mitochondria or prokaryotes?
- How and when did the nucleus evolve in eukaryotes?
- How and when did prokaryotes evolve?

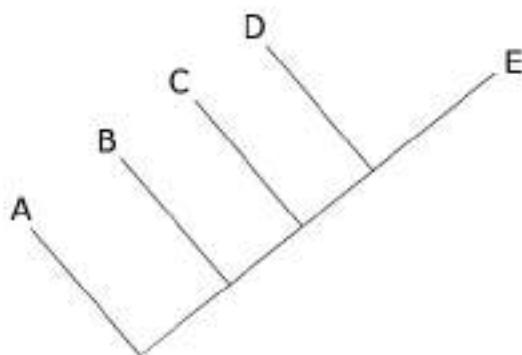

33.

The phylogeny above shows the evolution of traits in vertebrates. Based on this phylogeny, a student asks “Does this mean that lizards, frogs and rabbits all possessed hair and an egg with amnion at some point in their evolution?” Based on the phylogeny, how should you respond to the student?

- Hair and an amniotic egg were both possessed by all three species at some point in their evolution.
- Hair is only a characteristic found in the rabbit evolutionary history. The amniotic egg was possessed by both the rabbit and lizard, but not frogs, at some point in their evolutionary history.
- Hair is a characteristic only found in the rabbit evolutionary history. The amniotic egg was possessed by all three species at some point in their evolutionary history.
- Hair was possessed by all three species at some point in their evolutionary history. The amniotic egg was possessed by both the lizard and frog, but not the rabbit at some point in their evolutionary history.

34.

The tree above shows the phylogenetic relationships between four species. A scientist wishes to perform a genetic analysis on all four species in which she determines the number of genetic similarities between all four species. What would she likely find regarding the genetic similarities between species A, B, D and E?

- Species D and E would share more genetic similarities with each other than with species A and B, and vice versa.
- Species A and E would share more genetic similarities with each other than with species B and D, and vice versa.
- Species D and A would share more genetic similarities with each other than with species A and B, and vice versa.
- Species D and B would share more genetic similarities with each other than with species A and E.

35. What is the aim of scientists applying the maximum parsimony concept when creating phylogenetic trees?

- The scientists spend more time creating the phylogenetic table.
- Scientists find the shortest tree with the smallest number of changes.
- A complex, detailed phylogenetic tree diagram is created.
- The scientists spend more time researching the data for evolutionary connections.

36. Dolphins and fish have similar body shapes. Is this feature more likely a homologous or analogous trait? Explain your answer.

- a. Analogous-Dolphins are mammals and fish are not, thus their evolutionary paths are quite separate. They have similar body shapes because of their similar environment.
- b. Analogous-Dolphins and fish are both vertebrates, thus they share an evolutionary history, causing them to have similar body shapes.
- c. Homologous-Dolphins and fish are both vertebrates, thus they have a similar recent evolutionary history, causing them to have similar body shapes.
- d. Homologous-Dolphins are mammals and fish are not, thus their evolutionary paths are quite separate. They have similar body shapes because of their similar environment.

**37.** What effect has the advancement of DNA technology had on determining phylogeny?

- a. Morphologic and molecular information often disagree.
- b. Scientists are struggling with molecular systematics.
- c. Information is not reliable because organisms appear to be closely related when they are not.
- d. Computer programs help determine relatedness using DNA sequencing, and morphologic and molecular information is more effective in determining phylogeny.

**38.** Describe what maximum parsimony is used for in evolutionary biology.

- a. Maximum parsimony hypothesizes that organisms that share the most traits are the most likely to share a common ancestor.
- b. Maximum parsimony hypothesizes that organisms that share a common ancestor are more likely to have many traits in common.
- c. Maximum parsimony hypothesizes that events occurred in the simplest, most obvious way, and the pathway of evolution probably includes the fewest major events that coincide with the evidence at hand.
- d. Maximum parsimony hypothesizes that organisms that display homologous structures are closely related, while organisms that display analogous structures must have diverged much farther in the past.

**39.** The emu in Australia and ostrich in Africa are flightless birds that look similar. One proposed hypothesis was the birds descend from an early common ancestor that spread when the continents were connected. DNA analysis shows that emus and ostriches share more genetic homology with flying birds which live in the same region than with each other. What is the best explanation for these

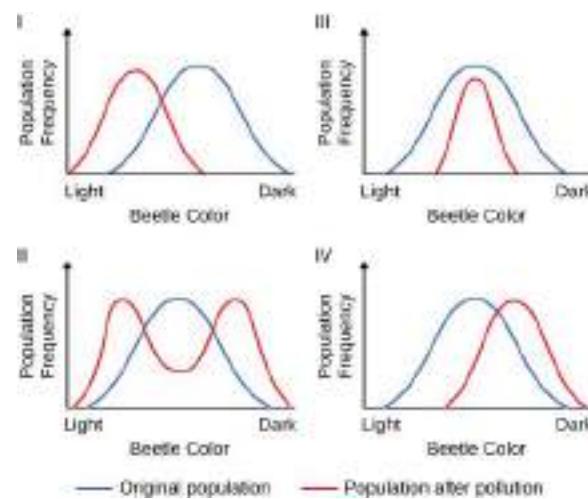

findings?

- a. This is an example of an early shared ancestor.
- b. This is an example of convergent evolution.
- c. This is an example of random DNA homology.
- d. This is an example of divergent evolution.

**40.** A scientist decides to investigate the evolutionary connection between closely related bacteria. Which gene would be a good choice to use for establishing relatedness, a very well conserved gene or a poorly conserved sequence? Explain your reasoning.

- a. A very well conserved gene would be a good choice, because well conserved genes undergo sufficient changes during relatively short times, which allows for the study of recent evolutionary events. Well-conserved genes do not undergo changes during short durations.
- b. A poorly conserved gene would be a good choice, because poorly conserved genes show sequence similarity, which is used as evidence of evolutionary relationships between sequences.
- c. A poorly conserved gene would be a good choice, because poorly conserved genes undergo sufficient changes during relatively short times, which allows for the study of recent evolutionary events.
- d. A very well conserved gene would be a good choice, because well conserved genes show sequence similarity, which is used as evidence of evolutionary relationships between sequences.

**41.**

In a hypothetical population of beetles, there is a wide variety of color, matching the range of coloration of the tree trunks on which the beetles hide from predators. The graphs below illustrate four possible changes in the beetle population as a result of a change in the environment due to pollution that darkened the tree trunks. What would be the most likely change in the coloration of the beetle

population after pollution and why?

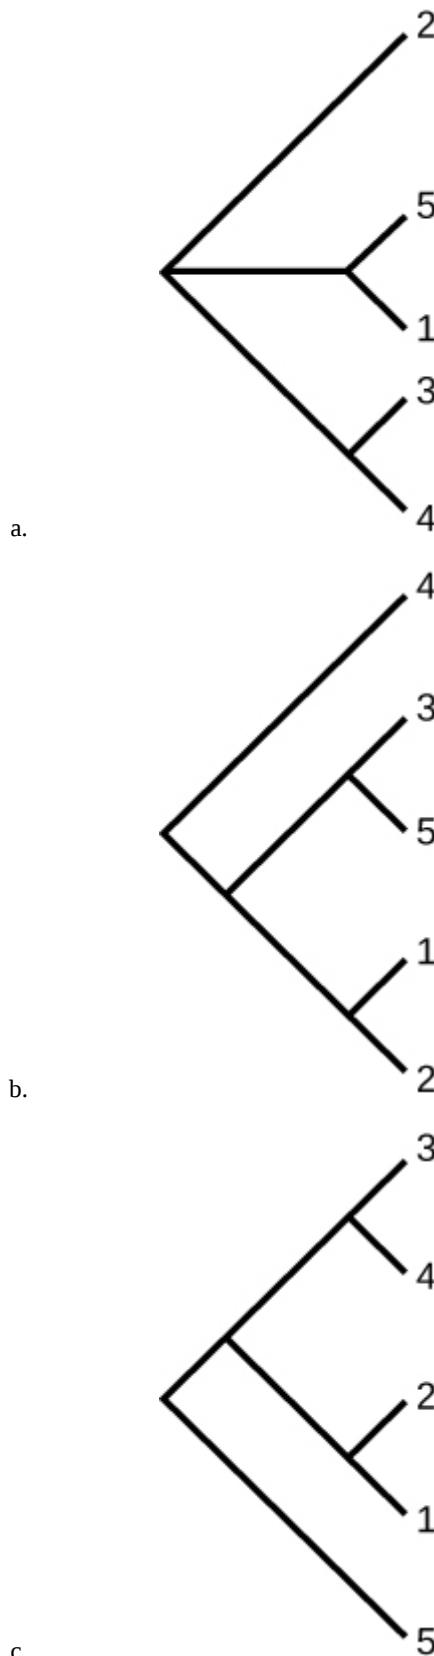

- The coloration range shifted toward more light-colored beetles, as in diagram I. The pollution helped the predators find the darkened tree trunks.
  - The coloration in the population split into two extremes, as in diagram II. Both the light-colored and the dark-colored beetles were able to hide on the darker tree trunks.
  - The coloration range became narrower, as in diagram III. The predators selected beetles at the color extremes.
  - The coloration in the population shifted toward more dark-colored beetles, as in diagram IV. The light-colored beetles were found more easily by the predators than were the dark-colored beetles.
- 42.** A population of rodents settles on the shore of an island close to the Arctic Circle. The landscape consists mainly of rocks. If the individuals are too large, they cannot hide in crevices to escape hawks. On the other hand, small bodies do not maintain internal temperature in cold weather. Show diagrammatically the change in the population and explain what selective pressures took place.

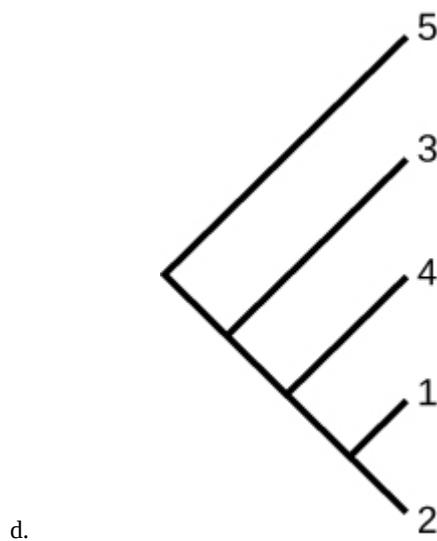

- directional selection
- stabilizing selection
- disruptive selection
- diversifying selection

- 43.** Five new species of bacteria were discovered in Antarctic ice core samples. The nucleotide (base) sequences of rRNA subunits were determined for the new species. The table below shows the number of nucleotide differences between the species.

| Species | 1 | 2 | 3  | 4  | 5  |
|---------|---|---|----|----|----|
| 1       | - | 3 | 19 | 18 | 27 |
| 2       |   | - | 19 | 18 | 26 |
| 3       |   |   | -  | 1  | 27 |
| 4       |   |   |    | -  | 27 |

Which of the following phylogenetic trees is most consistent with the data?

**44.** Draw the phylogenetic tree for the species below. Identify where on the tree each feature evolved.

|          | Annelids | Echinoderms | Feathers | Lungs | Vertebrates | Notochord |
|----------|----------|-------------|----------|-------|-------------|-----------|
| Snake    | Y        | N           | N        | Y     | Y           | Y         |
| Grouper  | Y        | Y           | Y        | Y     | Y           | Y         |
| Shark    | N        | N           | N        | N     | Y           | Y         |
| Frog     | N        | N           | N        | Y     | Y           | Y         |
| Lancelet | N        | N           | N        | N     | N           | Y         |

**Figure 20.20**

- a. The ostrich branched off first, followed by the snake, then the frog, then the shark and then the lancelet.
- b. The shark branched off first, followed by the lancelet, then the frog, then the ostrich and then the snake.
- c. The lancelet branched off first, followed by the shark, then the frog, then the snake and then the ostrich.
- d. The lancelet branched off first, followed by the shark, then the ostrich, then the snake and then the frog.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**49.**

**45.** Barbara McClintock discovered transposons while working on maize genetics. What are the transposons composed of when they are able to shift from one location to another?

- a. segments of RNA
- b. Plasmids
- c. segments of DNA
- d. proteins

**46.** What is Horizontal Gene Transfer (HGT)?

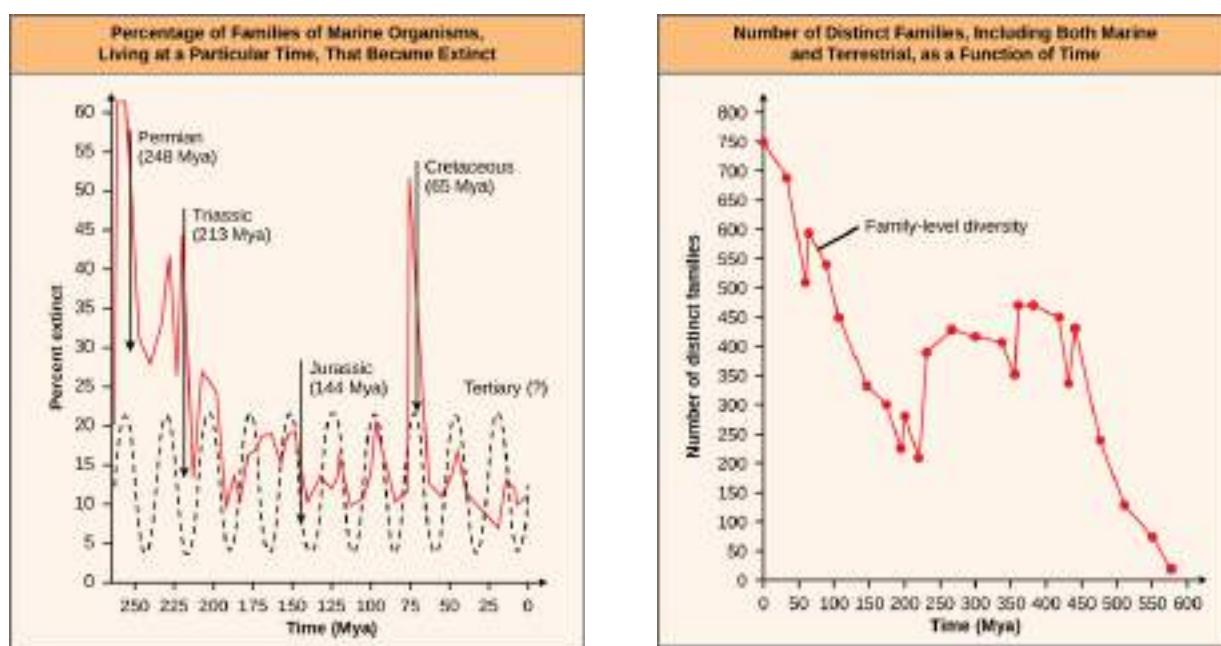

- a. the proposal that eukaryotes developed a nucleus first, and then their mitochondrion
- b. the transmission of genetic material from one species to another through mechanisms other than from parent to offspring
- c. the fusion of two prokaryotic genomes
- d. the division of kingdom in the taxonomic classification

**47.** What is referred to as the transfer of genes by a mechanism that does not involve asexual reproduction?

- a. web of life
- b. meiosis
- c. gene fusion
- d. horizontal gene transfer

**48.** Which of the following describes small, virus-like particles that act as a mechanism of gene transfer between prokaryotes?

- a. gene transfer agents
- b. horizontal gene transfer
- c. vertical gene transfer
- d. basal taxon

The figure shows a plot of the fraction, as a percentage, of families of marine organisms, living at a particular point in time that became extinct (vanished from the fossil record) in the next geological moment. These mass extinctions mark the ends of geologic periods. For example, the Triassic period ended around 213 million years ago (Mya).

A. The fact that evolution is an ongoing process is illustrated by these data. Whether the process displays a pattern involving regular intervals is a question that has been raised. Of those who believe periodicity is present, a period of 26 million years is favored. A wave with this periodicity is drawn on the figure. **Evaluate** the evidence provided in terms of agreement and disagreement with the marine extinction record.

The Cretaceous and Jurassic were periods of warm landmasses covered by a shallow sea. The ends of these periods are known to be due to asteroids that left a sedimentary trace. At the end of the Triassic, there is no evidence of an asteroid impact. Instead, there was massive volcanism associated with the opening of the Atlantic Ocean, a four-fold increase in carbon dioxide, and a 3–6 °C temperature rise (A. Marzoli et al., *Science*, 1999). Macrofossil, spore, and pollen data show that marine animal species declined much more than marine plant species (L. Mander et al., *Proc Natl Acad Sci*, 2010). The cause of the end of the Permian period is less uncertain, but an 8–9 °C temperature rise has been established (McElwain and Punyasena, *Trends in Ecology and Evolution*, 2007). Both terrestrial and marine taxa were affected.

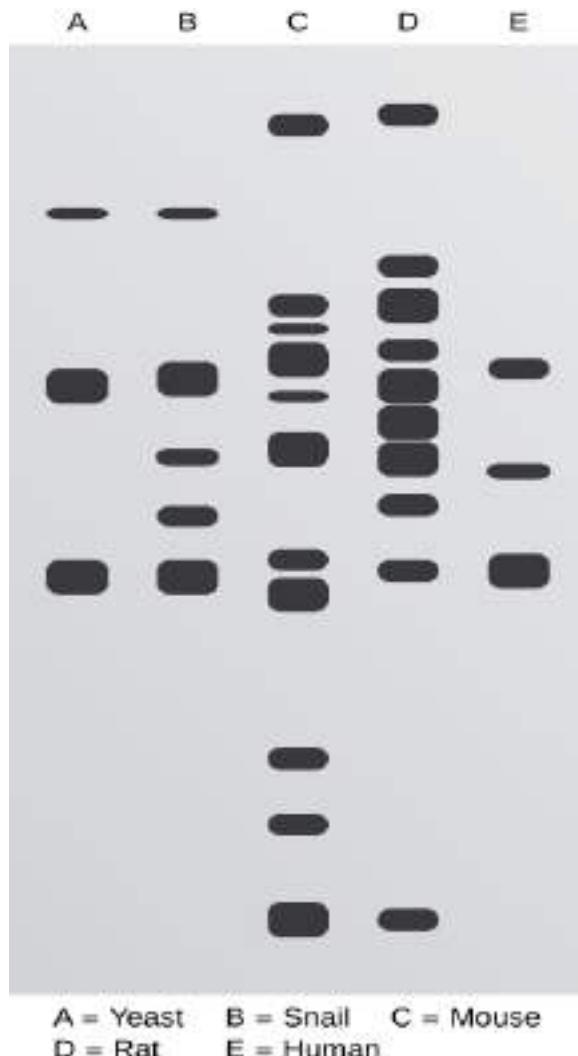

The graph estimates the number of distinct families, including both marine and terrestrial, as a function of time before the present. Note that the time scale for this graph is much longer than that of the previous graph.

**Figure 20.21**

**B. Analyze** this graph by:

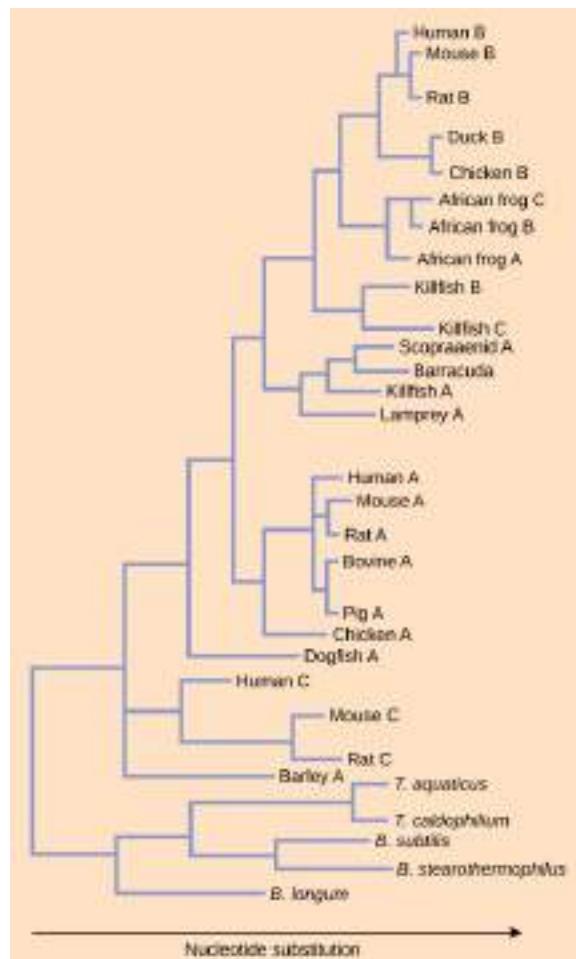

- identifying times of mass extinctions
- posing a question regarding any difference between the graph of extinctions of marine life and the graph of family-level diversity
- explaining the slope of the graph of family diversity following a mass extinction event

50.

Lactate dehydrogenase, an enzyme involved in glycolysis, from several species are compared using a Southern blot technique in the figure on the left: (A) yeast; (B) snail; (C) mouse; (D) rat; and (E) human (after K. Webster, *Journal of Experimental Biology* 2003).

A. **Justify** the claim that these data provide evidence that supports glycolysis as a conserved core property.

**Figure 20.22**

There are three forms of lactate dehydrogenase whose roles vary within an organism: LDH-A, -B, and -C. The question arises as to the origins of each. The cladogram on the right (after S. Tsuji et al., *Proc Natl Acad Sci* 1994) displays a proposed relatedness of variations in LDHs over many species.

B. Based on these data, **describe** the differences between the likely evolutionary sequences of LDH-A, -B, and -C in the African frog and in humans.

C. **Evaluate** the claim that in both species (African frog and human), LDH-C is the most recently evolved form of the enzyme.

51. Nucleotide-repeat sequences often occur within the intron, and sequence variation is neutral, that is, there is no selection. For example, the nucleotide-repeat sequence labeled A might be ACAGGGC, and the repeat sequence labeled B might be ACTGGT. Repeat sequences evolve by single-step duplication, deletion, and inversion, rather than by single-nucleotide substitution. Because these repeat sequences can be used to infer phylogeny, a phylogenetic tree can be hypothesized based on the principle of parsimony—the simplest explanation is the best explanation. Consider the repeat sequences A, B, C, D,

and E shown in the table below in which only inversions have occurred among five different species.

|           |       |
|-----------|-------|
| Species 1 | ABCDE |
| Species 2 | ADCBE |
| Species 3 | BACED |
| Species 4 | DACBE |
| Species 5 | ABCED |
| Species 6 | DEBCA |

**Table 20.2**

A. **Pose three questions** that can be used to infer the evolution of these five species.

B. Draw lines between nearest relatives **to construct a cladogram** that displays the relationships inferred by answers to your questions.

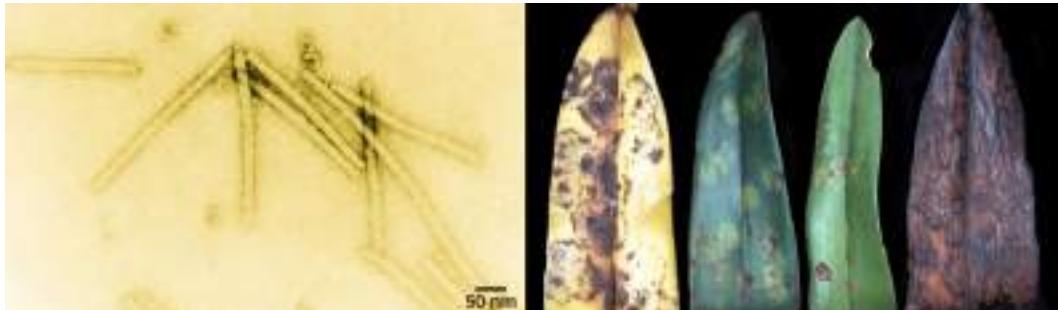

**Figure 20.23**

Carson (*Drosophila Genetics* 1983) used inversions in intron-repeat sequences of the fruit fly to infer evolution among the Hawaiian *Drosophila*. He further assigned the chronological sequence of islands on which the flies appeared by assuming (parsimoniously) that the geologically oldest of the volcanic islands was home to the oldest fly ancestor. When a fly or flies arrived on a newer island, speciation occurred, which, after a time, stabilized until another island hop occurred.

C. **Evaluate** Carson's reasoning for speciation and ongoing evolution.

D. **Pose two questions** whose pursuit could provide additional evidence of Carson's hypothesized evolutionary sequence.

# 21 | VIRUSES

**Figure 21.1** The tobacco mosaic virus (left), seen here by transmission electron microscopy, was the first virus to be discovered. The virus causes disease in tobacco and other plants, such as the orchid (right). (credit a: USDA ARS; credit b: modification of work by USDA Forest Service, Department of Plant Pathology Archive North Carolina State University; scale-bar data from Matt Russell)

## Chapter Outline

- 21.1: Viral Evolution, Morphology, and Classification**
- 21.2: Virus Infection and Hosts**
- 21.3: Prevention and Treatment of Viral Infections**
- 21.4: Other Acellular Entities: Prions and Viroids**

## Introduction

Have you ever had the measles? Like many other diseases, it begins with a fever, runny nose, and sore throat. Soon after, a rash begins to cover the body. In about 30% of measles cases other complications develop, such as pneumonia, encephalitis (swelling of the brain), and even death. Though the first recorded account of the measles was in the 9th century, it was not until 1912 that healthcare providers in the United States began reporting cases. Between 1912 and 1922, there were over 6,000 deaths related to the measles. This trend continued until 1963, when the first measles vaccine became available. The measles was declared eliminated from the United States in 2000 primarily due to the fact that the vast majority of children were receiving two doses of the vaccine. On January 23, 2015, the Center for Disease Control issued a health advisory about an outbreak of measles in several states. The outbreak originated at a popular theme park in California in December 2014 when an infected tourist from another country visited the theme park. Many of the people who became infected were not vaccinated or had not received the second dose of the vaccination. You can read more about the health advisory at the **CDC website (<http://Openstaxcollege.org/l/32measles>)**.

No one knows exactly when viruses emerged or from where they came, since viruses do not leave historical footprints such as fossils. Modern viruses are thought to be a mosaic of bits and pieces of nucleic acids picked up from various sources along their respective evolutionary paths. Viruses are **acellular**, parasitic entities that are not classified within any kingdom. Unlike most living organisms, viruses are not cells and cannot divide. Instead, they infect a host cell and use the host's replication processes to produce identical progeny virus particles. Viruses infect organisms as diverse as bacteria, plants, and animals. They exist in a netherworld between a living organism and a nonliving entity. Living things grow, metabolize, and reproduce. Viruses replicate, but to do so, they are entirely dependent on their host cells. They do not metabolize or grow, but are assembled in their mature form.

## 21.1 | Viral Evolution, Morphology, and Classification

In this section, you will explore the following questions:

- How were viruses first discovered and how are they detected?
- What three hypotheses describe the evolution of viruses?
- What is the basic structure of a virus?
- How are viruses classified?

### Connection for AP<sup>®</sup> Courses

The first organisms that originated about 3.5 billion years ago were prokaryotes that possessed the structures and metabolic processes associated with cells (refer to the Cell Structure chapter). As discussed in the chapter on cell structure, prokaryotic cells are much smaller than eukaryotic cells and inhabit just about every square inch of our planet, from the most inhospitable environments to the surface of the skin. Viruses are much smaller than prokaryotes and much simpler in structure. They must reproduce inside a host cell. Their origin is still a mystery to us, but we do know that they can make us very sick.

Viruses have a basic structure: a DNA or RNA core surrounded by an outer capsid of proteins. Some viruses have an outer phospholipid envelope. As we will explore in more detail, many viruses use some sort of glycoprotein to attach to their host cells. Viruses infect all known cell types and use the host cell's replication proteins and metabolic machinery to replicate. Classification of viruses is challenging, but one method categorizes them based on how they produce their mRNA. Retroviruses (also called RNA viruses) use the enzyme reverse transcriptase to transcribe DNA from RNA. (In the Genes and Proteins chapter we learned that the usual flow of genetic information is from DNA to RNA to protein.) Common viruses include bacteriophage T4, adenovirus, and HIV retrovirus.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP<sup>®</sup> Biology Curriculum Framework. The AP<sup>®</sup> Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP<sup>®</sup> Biology course, an inquiry-based laboratory experience, instructional activities, and AP<sup>®</sup> exam questions. A learning objective merges required content with one or more of the seven science practices.

|                                   |                                                                                                                                                                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Big Idea 3</b>                 | Living systems store, retrieve, transmit and respond to information essential to life processes.                                                                                                                                       |
| <b>Enduring Understanding 3.A</b> | Heritable information provides for continuity of life.                                                                                                                                                                                 |
| <b>Essential Knowledge</b>        | <b>3.A.1</b> DNA, and in some cases RNA, is the primary source of heritable information.                                                                                                                                               |
| <b>Science Practice</b>           | <b>6.5</b> The student can evaluate alternative scientific explanations.                                                                                                                                                               |
| <b>Learning Objective</b>         | <b>3.1</b> The student is able to construct scientific explanations that use the structures and mechanisms of DNA and RNA to support the claim that DNA and, in some cases, that RNA are the primary sources of heritable information. |

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

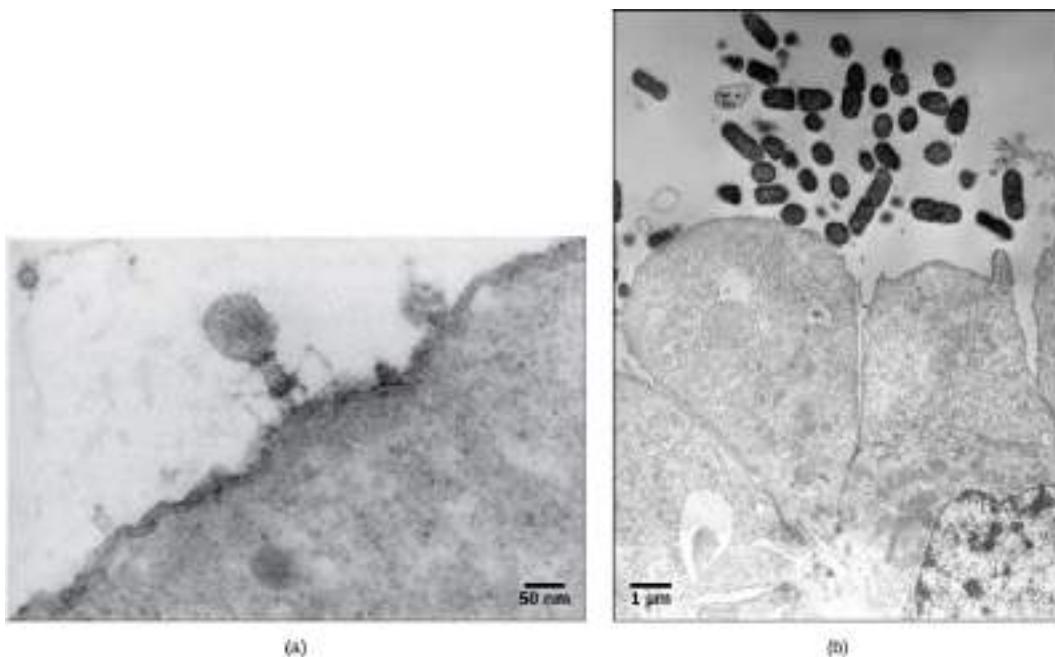

[APLO 2.20][APLO 3.3][APLO 3.29][APLO 3.30][APLO 2.22][APLO 2.26][APLO 1.31][APLO 1.27][APLO 1.30]

### Discovery and Detection

Viruses were first discovered after the development of a porcelain filter, called the Chamberland-Pasteur filter, which could remove all bacteria visible in the microscope from any liquid sample. In 1886, Adolph Meyer demonstrated that a disease of

tobacco plants, tobacco mosaic disease, could be transferred from a diseased plant to a healthy one via liquid plant extracts. In 1892, Dmitri Ivanowski showed that this disease could be transmitted in this way even after the Chamberland-Pasteur filter had removed all viable bacteria from the extract. Still, it was many years before it was proven that these “filterable” infectious agents were not simply very small bacteria but were a new type of very small, disease-causing particle.

**Virions**, single virus particles, are very small, about 20–250 nanometers in diameter. These individual virus particles are the infectious form of a virus outside the host cell. Unlike bacteria (which are about 100-times larger), we cannot see viruses with a light microscope, with the exception of some large virions of the poxvirus family. It was not until the development of the electron microscope in the late 1930s that scientists got their first good view of the structure of the tobacco mosaic virus (TMV) (Figure 21.1) and other viruses (Figure 21.2). The surface structure of virions can be observed by both scanning and transmission electron microscopy, whereas the internal structures of the virus can only be observed in images from a transmission electron microscope. The use of these technologies has allowed for the discovery of many viruses of all types of living organisms. They were initially grouped by shared morphology. Later, groups of viruses were classified by the type of nucleic acid they contained, DNA or RNA, and whether their nucleic acid was single- or double-stranded. More recently, molecular analysis of viral replicative cycles has further refined their classification.

**Figure 21.2** In these transmission electron micrographs, (a) a virus is dwarfed by the bacterial cell it infects, while (b) these *E. coli* cells are dwarfed by cultured colon cells. ## Evolution of Viruses

Although biologists have accumulated a significant amount of knowledge about how present-day viruses evolve, much less is known about how viruses originated in the first place. When exploring the evolutionary history of most organisms, scientists can look at fossil records and similar historic evidence. However, viruses do not fossilize, so researchers must conjecture by investigating how today’s viruses evolve and by using biochemical and genetic information to create speculative virus histories.

While most findings agree that viruses don’t have a single common ancestor, scholars have yet to find a single hypothesis about virus origins that is fully accepted in the field. One such hypothesis, called devolution or the regressive hypothesis, proposes to explain the origin of viruses by suggesting that viruses evolved from free-living cells. However, many components of how this process might have occurred are a mystery. A second hypothesis (called escapist or the progressive hypothesis) accounts for viruses having either an RNA or a DNA genome and suggests that viruses originated from RNA and DNA molecules that escaped from a host cell. A third hypothesis posits a system of self-replication similar to that of other self-replicating molecules, likely evolving alongside the cells they rely on as hosts; studies of some plant pathogens support this hypothesis.

As technology advances, scientists may develop and refine further hypotheses to explain the origin of viruses. The emerging field called virus molecular systematics attempts to do just that through comparisons of sequenced genetic material. These

researchers hope to one day better understand the origin of viruses, a discovery that could lead to advances in the treatments for the ailments they produce.

## Viral Morphology

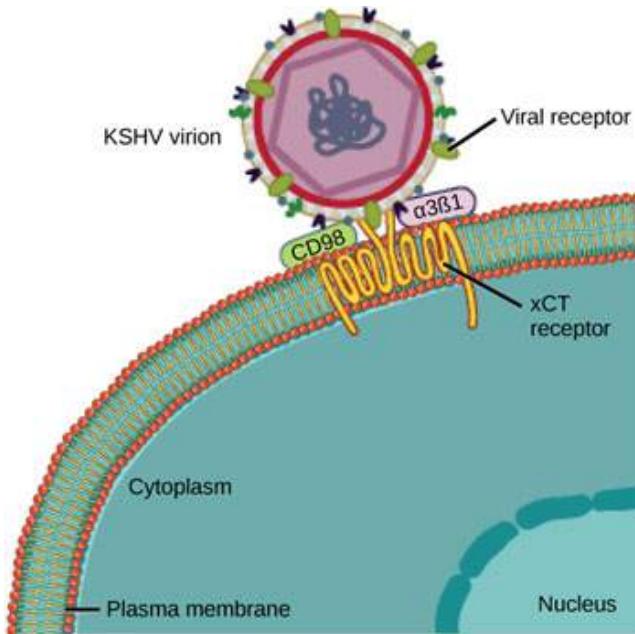

Viruses are acellular, meaning they are biological entities that do not have a cellular structure. They therefore lack most of the components of cells, such as organelles, ribosomes, and the plasma membrane. A virion consists of a nucleic acid core, an outer protein coating or **capsid**, and sometimes an outer **envelope** made of protein and phospholipid membranes derived from the host cell. Viruses may also contain additional proteins, such as enzymes. The most obvious difference between members of viral families is their morphology, which is quite diverse. An interesting feature of viral complexity is that the complexity of the host does not correlate with the complexity of the virion. Some of the most complex virion structures are observed in bacteriophages, viruses that infect the simplest living organisms, bacteria.

### Morphology

Viruses come in many shapes and sizes, but these are consistent and distinct for each viral family. All virions have a nucleic acid genome covered by a protective layer of proteins, called a capsid. The capsid is made up of protein subunits called **capsomeres**. Some viral capsids are simple polyhedral “spheres,” whereas others are quite complex in structure.

In general, the shapes of viruses are classified into four groups: filamentous, isometric (or icosahedral), enveloped, and head and tail. Filamentous viruses are long and cylindrical. Many plant viruses are filamentous, including TMV. Isometric viruses have shapes that are roughly spherical, such as poliovirus or herpesviruses. Enveloped viruses have membranes surrounding capsids. Animal viruses, such as HIV, are frequently enveloped. Head and tail viruses infect bacteria and have a head that is similar to icosahedral viruses and a tail shape like filamentous viruses.

Many viruses use some sort of glycoprotein to attach to their host cells via molecules on the cell called **viral receptors** (**Figure 21.3**). For these viruses, attachment is a requirement for later penetration of the cell membrane, so they can complete their replication inside the cell. The receptors that viruses use are molecules that are normally found on cell surfaces and have their own physiological functions. Viruses have simply evolved to make use of these molecules for their own replication. For example, HIV uses the CD4 molecule on T lymphocytes as one of its receptors. CD4 is a type of molecule called a cell adhesion molecule, which functions to keep different types of immune cells in close proximity to each other during the generation of a T lymphocyte immune response.

**Figure 21.3** The KSHV virus binds the xCT receptor on the surface of human cells. xCT receptors protect cells against stress. Stressed cells express more xCT receptors than non-stressed cells. The KSHV virion causes cells to become stressed, thereby increasing expression of the receptor to which it binds. (credit: modification of work by NIAID, NIH)

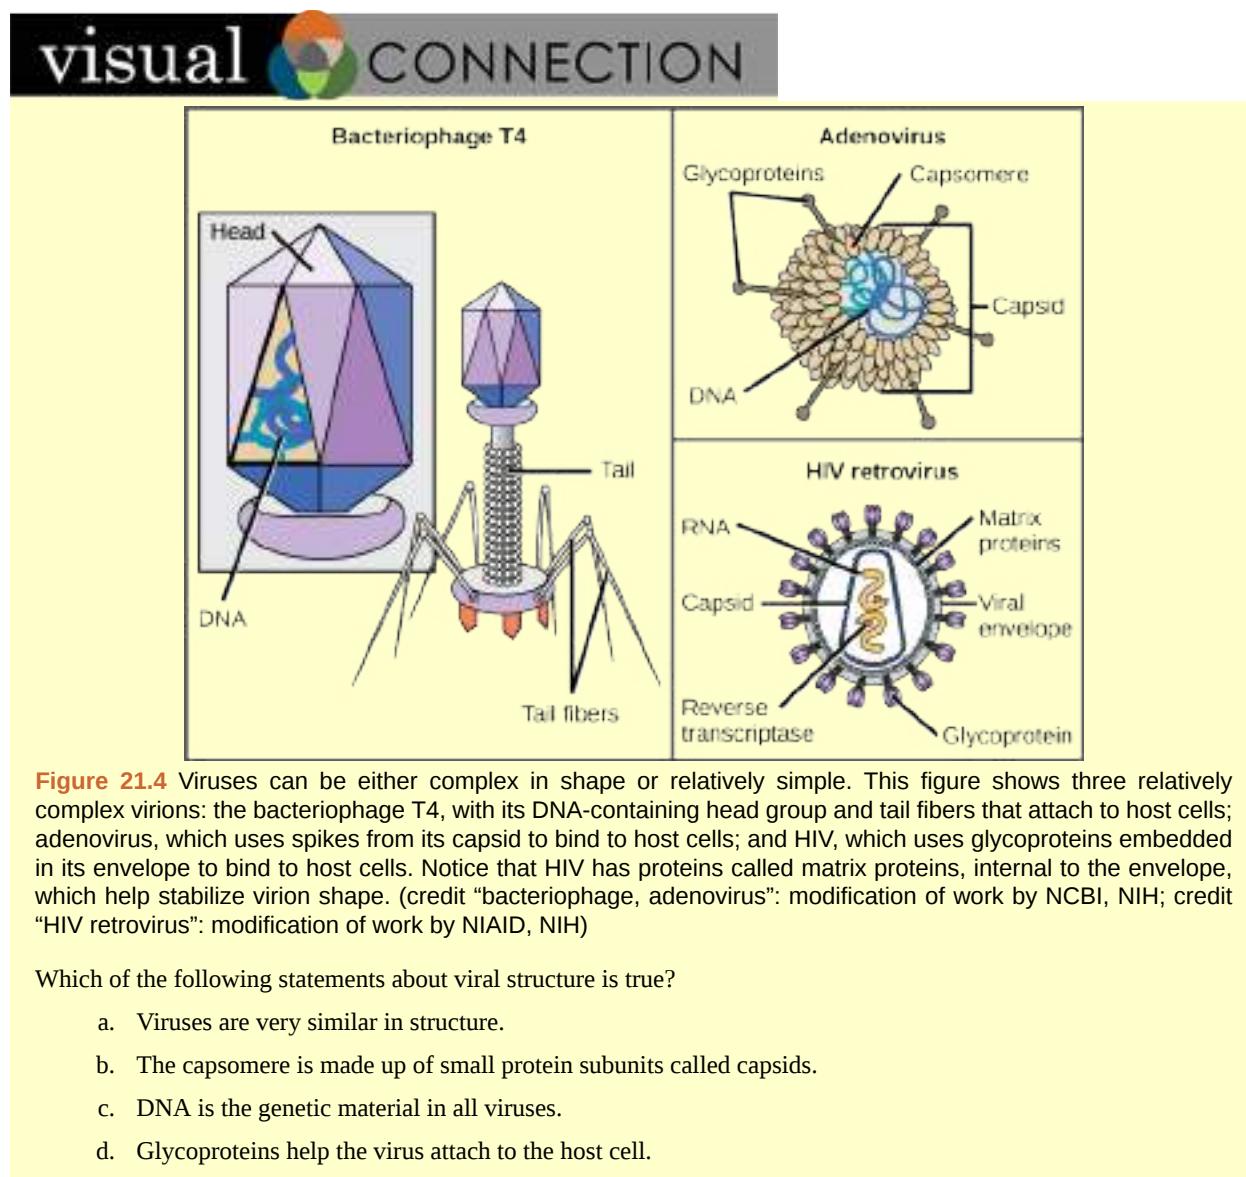

Among the most complex virions known, the T4 bacteriophage, which infects the *Escherichia coli* bacterium, has a tail structure that the virus uses to attach to host cells and a head structure that houses its DNA.

Adenovirus, a non-enveloped animal virus that causes respiratory illnesses in humans, uses glycoprotein spikes protruding from its capsomeres to attach to host cells. Non-enveloped viruses also include those that cause polio (poliovirus), plantar

warts (papillomavirus), and hepatitis A (hepatitis A virus).

Enveloped virions like HIV, the causative agent in AIDS, consist of nucleic acid (RNA in the case of HIV) and capsid proteins surrounded by a phospholipid bilayer envelope and its associated proteins. Glycoproteins embedded in the viral envelope are used to attach to host cells. Other envelope proteins are the **matrix proteins** that stabilize the envelope and often play a role in the assembly of progeny virions. Chicken pox, influenza, and mumps are examples of diseases caused by viruses with envelopes. Because of the fragility of the envelope, non-enveloped viruses are more resistant to changes in temperature, pH, and some disinfectants than enveloped viruses.

Overall, the shape of the virion and the presence or absence of an envelope tell us little about what disease the virus may cause or what species it might infect, but they are still useful means to begin viral classification (**Figure 21.4**).

**Figure 21.4** Viruses can be either complex in shape or relatively simple. This figure shows three relatively complex virions: the bacteriophage T4, with its DNA-containing head group and tail fibers that attach to host cells; adenovirus, which uses spikes from its capsid to bind to host cells; and HIV, which uses glycoproteins embedded in its envelope to bind to host cells. Notice that HIV has proteins called matrix proteins, internal to the envelope, which help stabilize virion shape. (credit “bacteriophage, adenovirus”: modification of work by NCBI, NIH; credit “HIV retrovirus”: modification of work by NIAID, NIH)

Which of the following statements about viral structure is true?

- Viruses are very similar in structure.
- The capsomere is made up of small protein subunits called capsids.
- DNA is the genetic material in all viruses.
- Glycoproteins help the virus attach to the host cell.

### Types of Nucleic Acid

Unlike nearly all living organisms that use DNA as their genetic material, viruses may use either DNA or RNA as theirs. The **virus core** contains the genome or total genetic content of the virus. Viral genomes tend to be small, containing only those genes that encode proteins that the virus cannot get from the host cell. This genetic material may be single- or double-stranded. It may also be linear or circular. While most viruses contain a single nucleic acid, others have genomes that have several, which are called segments.

In DNA viruses, the viral DNA directs the host cell's replication proteins to synthesize new copies of the viral genome and to transcribe and translate that genome into viral proteins. DNA viruses cause human diseases such as chickenpox and hepatitis B.

RNA viruses contain only RNA as their genetic material. To replicate their genomes in the host cell, the RNA viruses encode enzymes that can replicate RNA into DNA, which cannot be done by the host cell. These RNA polymerase enzymes are more likely to make copying errors than DNA polymerases, and therefore often make mistakes during transcription. For this reason, mutations in RNA viruses occur more frequently than in DNA viruses. This causes them to change and adapt more rapidly to their host. Human diseases caused by RNA viruses include hepatitis C, measles, and rabies.

## Virus Classification

To understand the features shared among different groups of viruses, a classification scheme is necessary. As most viruses are not thought to have evolved from a common ancestor, however, the methods that scientists use to classify living things are not very useful. Biologists have used several classification systems in the past, based on the morphology and genetics of the different viruses. However, these earlier classification methods grouped viruses differently, based on which features of the virus they were using to classify them. The most commonly used classification method today is called the Baltimore classification scheme and is based on how messenger RNA (mRNA) is generated in each particular type of virus.

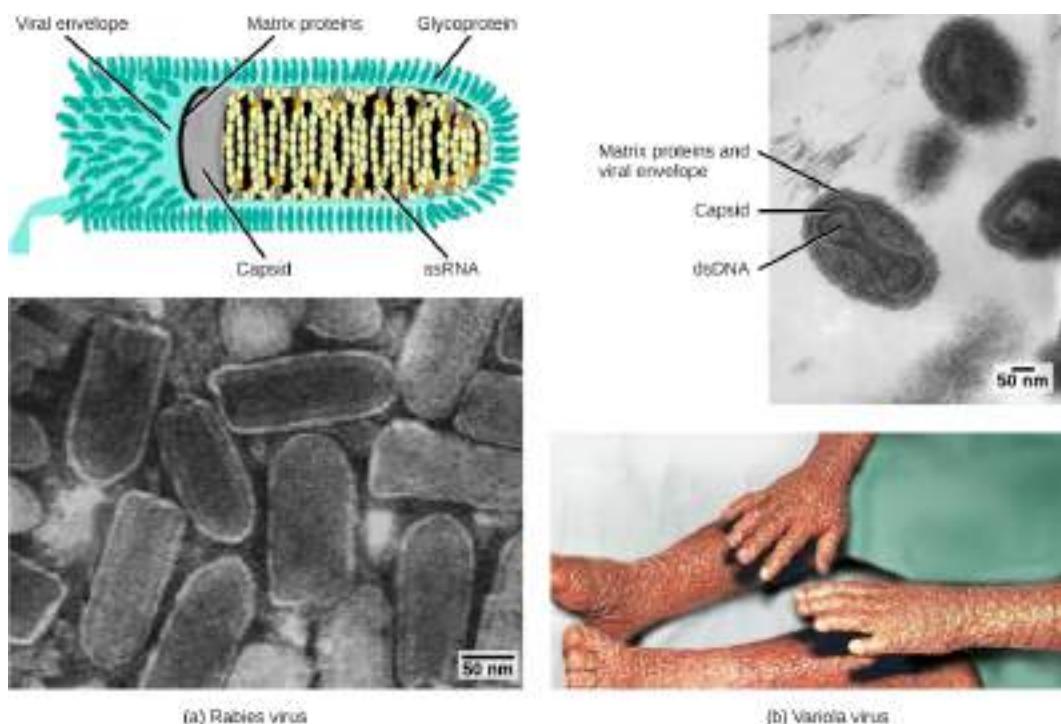

### **Past Systems of Classification**

Viruses are classified in several ways: by factors such as their core content (Table 21.1 and Figure 21.3), the structure of their capsids, and whether they have an outer envelope. The type of genetic material (DNA or RNA) and its structure (single- or double-stranded, linear or circular, and segmented or non-segmented) are used to classify the virus core structures.

### **Virus Classification by Genome Structure and Core**

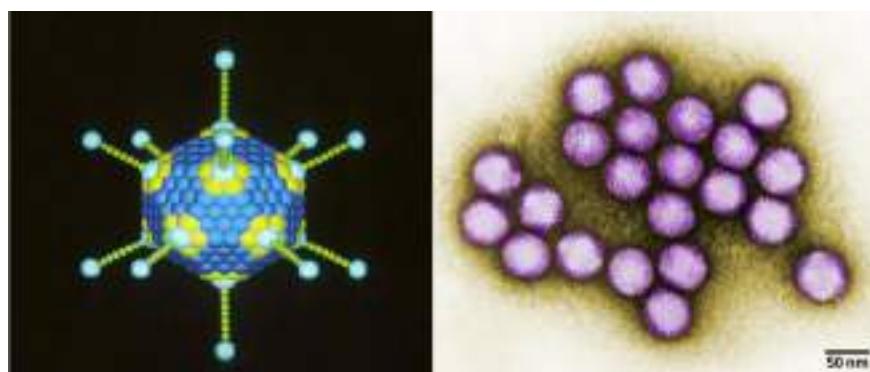

| Core Classifications                                                   | Examples                                                  |
|------------------------------------------------------------------------|-----------------------------------------------------------|
| RNA                                                                    | Rabies virus, retroviruses                                |
| DNA                                                                    | Herpesviruses, smallpox virus                             |
| Single-stranded                                                        | Rabies virus, retroviruses                                |
| Double-stranded                                                        | Herpesviruses, smallpox virus                             |
| Linear                                                                 | Rabies virus, retroviruses, herpesviruses, smallpox virus |
| Circular                                                               | Papillomaviruses, many bacteriophages                     |
| Non-segmented: genome consists of a single segment of genetic material | Parainfluenza viruses                                     |
| Segmented: genome is divided into multiple segments                    | Influenza viruses                                         |

**Table 21.1**

**Figure 21.5** Viruses are classified based on their core genetic material and capsid design. (a) Rabies virus has a single-stranded RNA (ssRNA) core and an enveloped helical capsid, whereas (b) variola virus, the causative agent of smallpox, has a double-stranded DNA (dsDNA) core and a complex capsid. Rabies transmission occurs when saliva from an infected mammal enters a wound. The virus travels through neurons in the peripheral nervous system to the central nervous system where it impairs brain function, and then travels to other tissues. The virus can infect any mammal, and most die within weeks of infection. Smallpox is a human virus transmitted by inhalation of the variola virus, localized in the skin, mouth, and throat, which causes a characteristic rash. Before its eradication in 1979, infection resulted in a 30–35 percent mortality rate. (credit “rabies diagram”: modification of work by CDC; “rabies micrograph”: modification of work by Dr. Fred Murphy, CDC; credit “small pox micrograph”: modification of work by Dr. Fred Murphy, Sylvia Whitfield, CDC; credit “smallpox photo”: modification of work by CDC; scale-bar data from Matt Russell)

Viruses can also be classified by the design of their capsids (Figure 21.4 and Figure 21.5). Capsids are classified as naked icosahedral, enveloped icosahedral, enveloped helical, naked helical, and complex (Figure 21.6 and Figure 21.7). The type of genetic material (DNA or RNA) and its structure (single- or double-stranded, linear or circular, and segmented or non-segmented) are used to classify the virus core structures (Table 21.2).

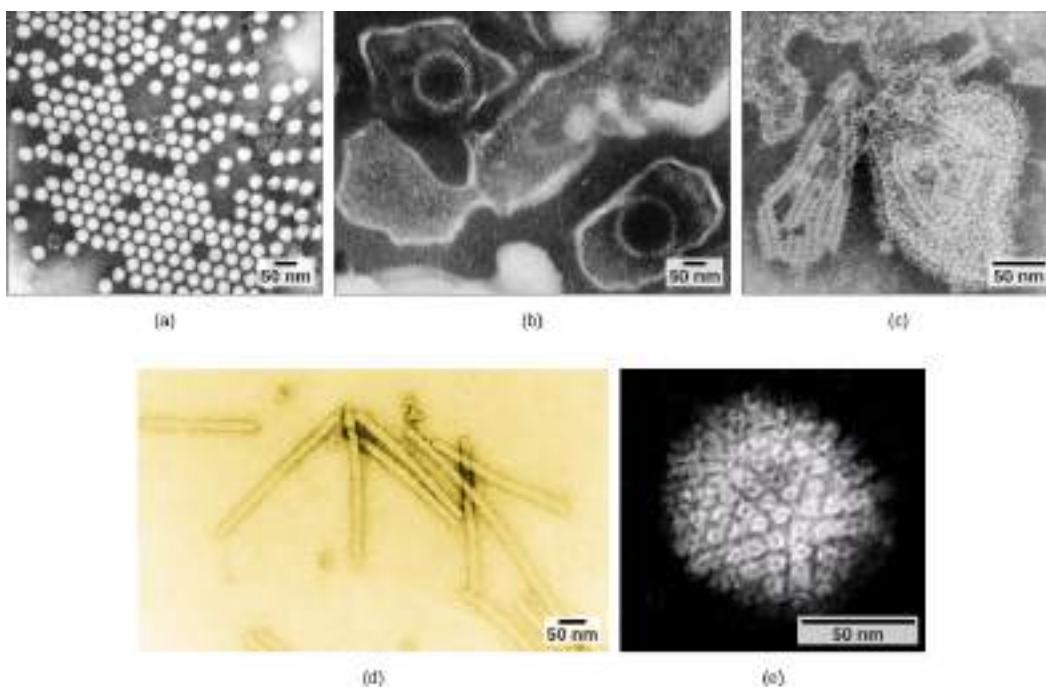

**Figure 21.6** Adenovirus (left) is depicted with a double-stranded DNA genome enclosed in an icosahedral capsid that is 90–100 nm across. The virus, shown clustered in the micrograph (right), is transmitted orally and causes a variety of illnesses in vertebrates, including human eye and respiratory infections. William Gary, Jr., CDC; scale-bar data from Matt Russell)

## Virus Classification by Capsid Structure

| Capsid Classification                                                                           | Examples                                                                           |
|-------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Naked icosahedral                                                                               | Hepatitis A virus, polioviruses                                                    |
| Enveloped icosahedral                                                                           | Epstein-Barr virus, herpes simplex virus, rubella virus, yellow fever virus, HIV-1 |
| Enveloped helical                                                                               | Influenza viruses, mumps virus, measles virus, rabies virus                        |
| Naked helical                                                                                   | Tobacco mosaic virus                                                               |
| Complex with many proteins; some have combinations of icosahedral and helical capsid structures | Herpesviruses, smallpox virus, hepatitis B virus, T4 bacteriophage                 |

**Table 21.2**

**Figure 21.7** Transmission electron micrographs of various viruses show their structures. The capsid of the (a) polio virus is naked icosahedral; (b) the Epstein-Barr virus capsid is enveloped icosahedral; (c) the mumps virus capsid is an enveloped helix; (d) the tobacco mosaic virus capsid is naked helical; and (e) the herpesvirus capsid is complex. (credit a: modification of work by Dr. Fred Murphy, Sylvia Whitfield; credit b: modification of work by Liza Gross; credit c: modification of work by Dr. F. A. Murphy, CDC; credit d: modification of work by USDA ARS; credit e: modification of work by Linda Stannard, Department of Medical Microbiology, University of Cape Town, South Africa, NASA; scale-bar data from Matt Russell)

### Baltimore Classification

The most commonly used system of virus classification was developed by Nobel Prize-winning biologist David Baltimore in the early 1970s. In addition to the differences in morphology and genetics mentioned above, the Baltimore classification scheme groups viruses according to how the mRNA is produced during the replicative cycle of the virus.

**Group I** viruses contain double-stranded DNA (dsDNA) as their genome. Their mRNA is produced by transcription in much the same way as with cellular DNA. **Group II** viruses have single-stranded DNA (ssDNA) as their genome. They convert their single-stranded genomes into a dsDNA intermediate before transcription to mRNA can occur. **Group III** viruses use dsRNA as their genome. The strands separate, and one of them is used as a template for the generation of mRNA using the RNA-dependent RNA polymerase encoded by the virus. **Group IV** viruses have ssRNA as their genome with a positive polarity. **Positive polarity** means that the genomic RNA can serve directly as mRNA. Intermediates of dsRNA, called **replicative intermediates**, are made in the process of copying the genomic RNA. Multiple, full-length RNA strands

of negative polarity (complementary to the positive-stranded genomic RNA) are formed from these intermediates, which may then serve as templates for the production of RNA with positive polarity, including both full-length genomic RNA and shorter viral mRNAs. **Group V** viruses contain ssRNA genomes with a **negative polarity**, meaning that their sequence is complementary to the mRNA. As with Group IV viruses, dsRNA intermediates are used to make copies of the genome and produce mRNA. In this case, the negative-stranded genome can be converted directly to mRNA. Additionally, full-length positive RNA strands are made to serve as templates for the production of the negative-stranded genome. **Group VI** viruses have diploid (two copies) ssRNA genomes that must be converted, using the enzyme **reverse transcriptase**, to dsDNA; the dsDNA is then transported to the nucleus of the host cell and inserted into the host genome. Then, mRNA can be produced by transcription of the viral DNA that was integrated into the host genome. **Group VII** viruses have partial dsDNA genomes and make ssRNA intermediates that act as mRNA, but are also converted back into dsDNA genomes by reverse transcriptase, necessary for genome replication. The characteristics of each group in the Baltimore classification are summarized in **Table 21.3** with examples of each group.

### Baltimore Classification

| Group | Characteristics                                        | Mode of mRNA Production                                                                                                                                            | Example                               |
|-------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| I     | Double-stranded DNA                                    | mRNA is transcribed directly from the DNA template                                                                                                                 | Herpes simplex (herpesvirus)          |
| II    | Single-stranded DNA                                    | DNA is converted to double-stranded form before RNA is transcribed                                                                                                 | Canine parvovirus (parvovirus)        |
| III   | Double-stranded RNA                                    | mRNA is transcribed from the RNA genome                                                                                                                            | Childhood gastroenteritis (rotavirus) |
| IV    | Single stranded RNA (+)                                | Genome functions as mRNA                                                                                                                                           | Common cold (picornavirus)            |
| V     | Single stranded RNA (-)                                | mRNA is transcribed from the RNA genome                                                                                                                            | Rabies (rhabdovirus)                  |
| VI    | Single stranded RNA viruses with reverse transcriptase | Reverse transcriptase makes DNA from the RNA genome; DNA is then incorporated in the host genome; mRNA is transcribed from the incorporated DNA                    | Human immunodeficiency virus (HIV)    |
| VII   | Double stranded DNA viruses with reverse transcriptase | The viral genome is double-stranded DNA, but viral DNA is replicated through an RNA intermediate; the RNA may serve directly as mRNA or as a template to make mRNA | Hepatitis B virus (hepatnavirus)      |

**Table 21.3**

## 21.2 | Virus Infection and Hosts

In this section, you will explore the following questions:

- What are the steps in viral replication, and what events occur in each?
- What is the difference between the lytic and lysogenic cycles of virus replication?
- How are plant and animal viruses transmitted, what are examples of virus-caused diseases in plants and animals, and what are the economic impacts of plant viruses?

## Connection for AP<sup>®</sup> Courses

Viruses differ from other organisms in their method of replication. Viruses replicate within a living host cell, producing changes in the cell that often result in the death of the infected cell. Thus, viruses are considered intracellular parasites. Viral replication involves several steps: attachment, penetration, replication, assembly, and release. Viruses are host-specific because they only can attach to and infect cells of certain organisms. Cells that a virus may use to replicate are called **permissive**. The virus attacks the host cell by first attaching to a specific receptor site on the membrane of the host cell. Next, the viral nucleic acid, either DNA or RNA, enters the host cell, either naked, leaving the protein capsid behind, or with the capsid. If the capsid enters the cell, an additional uncoating step is needed. Viral nucleic acid then becomes available for replication and transcription. The last stage of viral replication is the release of the new virions produced by the host that are able to infect other cells. Depending on the type of virus, the replication cycle facilitates the transfer of genetic information through the **lytic** and **lysogenic** cycles.

**Bacteriophages**, such as T4 are viruses that infect bacterial cells, can enter both the lytic and lysogenic cycles. Animal viruses cause a variety of infections, for example, hepatitis C, herpes, HPV, colds, and flu. Occasionally, viruses can “hide” and remain latent (dormant) in cells such as nerve or liver cells for months, or even years; for example, the varicella-zoster virus that causes chickenpox in children can reactivate in adults to cause the painful condition known as “shingles.” Oncogenic viruses in animals can cause cancer by interfering with the regulation of the host cell cycle. Plant viruses can cause considerable economic damage caused by poor crop quality and quantity globally.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP<sup>®</sup> Biology Curriculum Framework. The AP<sup>®</sup> Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP<sup>®</sup> Biology course, an inquiry-based laboratory experience, instructional activities, and AP<sup>®</sup> exam questions. A learning objective merges required content with one or more of the seven science practices.

## Steps of Virus Infections

A virus must use cell processes to replicate. The viral replication cycle can produce dramatic biochemical and structural changes in the host cell, which may cause cell damage. These changes, called **cytopathic** (causing cell damage) effects, can change cell functions or even destroy the cell. Some infected cells, such as those infected by the common cold virus known as rhinovirus, die through **lysis** (bursting) or apoptosis (programmed cell death), releasing all progeny virions at once. The symptoms of viral diseases result from the immune response to the virus, which attempts to control and eliminate

the virus from the body, and from cell damage caused by the virus. Many animal viruses leave the infected cells of the immune system by a process known as **budding**, where virions leave the cell individually. During the budding process, the cell does not undergo lysis and is not immediately killed. However, the damage to the cells that the virus infects may make it impossible for the cells to function normally, even though the cells remain alive for a period of time. Most productive viral infections follow similar steps in the virus replication cycle: attachment, penetration, uncoating, replication, assembly, and release ([Figure 21.8](#)).

### Attachment

A virus attaches to a specific receptor site on the host cell membrane through attachment proteins in the capsid or via glycoproteins embedded in the viral envelope. The specificity of this interaction determines the host—and the cells within the host—that can be infected by a particular virus. This can be illustrated by thinking of several keys and several locks, where each key will fit only one specific lock.

This [video](#) (<http://openstaxcollege.org/l/influenza>) explains how influenza attacks the body.

The video shows how viruses replicate in our body. Using the terminology provided in the video, explain how a virus attaches to a cell in our body?

- a. When the virus capsule makes contact with the cell, it bursts, and then the virions attach to the cell.
- b. If a key on the virus fits a lock on the surface of the cell, the virus will attach to the cell.
- c. The keys automatically attach to all the locks.
- d. The welcoming committee interlocks with the virus.

### Entry

The nucleic acid of bacteriophages enters the host cell naked, leaving the capsid outside the cell. Plant and animal viruses can enter through endocytosis, in which the cell membrane surrounds and engulfs the entire virus. Some enveloped viruses enter the cell when the viral envelope fuses directly with the cell membrane. Once inside the cell, the viral capsid is degraded, and the viral nucleic acid is released, which then becomes available for replication and transcription.

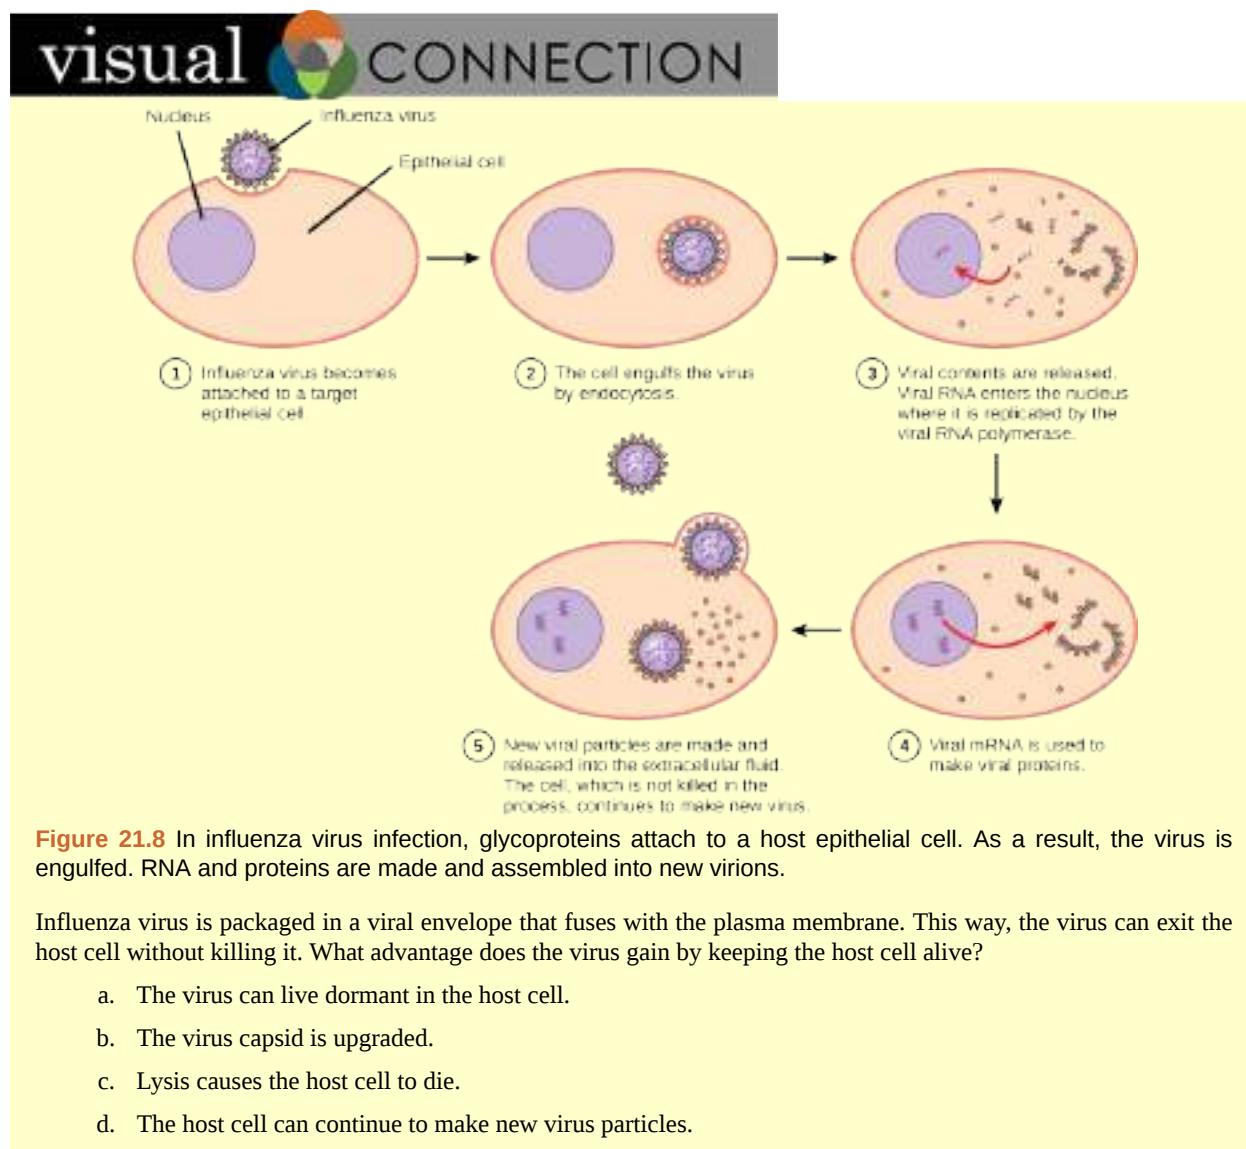

### Replication and Assembly

The replication mechanism depends on the viral genome. DNA viruses usually use host cell proteins and enzymes to make additional DNA that is transcribed to messenger RNA (mRNA), which is then used to direct protein synthesis. RNA viruses usually use the RNA core as a template for synthesis of viral genomic RNA and mRNA. The viral mRNA directs the host cell to synthesize viral enzymes and capsid proteins, and assemble new virions. Of course, there are exceptions to this pattern. If a host cell does not provide the enzymes necessary for viral replication, viral genes supply the information to direct synthesis of the missing proteins. **Retroviruses** have an RNA genome that must be reverse transcribed into DNA, which then is incorporated into the host cell genome. They are within group VI of the Baltimore classification scheme. To convert RNA into DNA, retroviruses must contain genes that encode the virus-specific enzyme reverse transcriptase that transcribes an RNA template to DNA. Reverse transcription never occurs in uninfected host cells—the needed enzyme reverse transcriptase is only derived from the expression of viral genes within the infected host cells. The fact that some retroviruses produce some of its own enzymes not found in the host has allowed researchers to develop drugs that inhibit these enzymes. These drugs inhibit replication by reducing the activity of the enzyme without affecting the host's metabolism. This approach has led to the development of a variety of drugs used to treat these viruses and has been effective at reducing the number of infectious virions (copies of viral RNA) in the blood to non-detectable levels in people affected with the virus.

### Egress

The last stage of viral replication is the release of the new virions produced in the host organism, where they are able to

infect adjacent cells and repeat the replication cycle. As you've learned, some viruses are released when the host cell dies, and other viruses can leave infected cells by budding through the membrane without directly killing the cell.

**Figure 21.8** In influenza virus infection, glycoproteins attach to a host epithelial cell. As a result, the virus is engulfed. RNA and proteins are made and assembled into new virions.

Influenza virus is packaged in a viral envelope that fuses with the plasma membrane. This way, the virus can exit the host cell without killing it. What advantage does the virus gain by keeping the host cell alive?

- a. The virus can live dormant in the host cell.
- b. The virus capsid is upgraded.
- c. Lysis causes the host cell to die.
- d. The host cell can continue to make new virus particles.

Visit this **website** (<http://openstaxcollege.org/l/32virusrep>) to learn about viral replication.

How do viruses get inside a host cell?

- a. To get inside the host cell, the virus forces the cell to lyse, or break open.
- b. To get inside a host cell, the virus produces proteins and copies its genome.
- c. To get inside a host cell, the virus attaches to a specific receptor site on the host cell.
- d. To get inside a host cell, the virus can fuse the membrane of the cell.

## Different Hosts and Their Viruses

As you've learned, viruses are often very specific as to which hosts and which cells within the host they will infect. This feature of a virus makes it specific to one or a few species of life on Earth. On the other hand, so many different types of viruses exist on Earth that nearly every living organism has its own set of viruses that tries to infect its cells. Even the smallest and simplest of cells, prokaryotic bacteria, may be attacked by specific types of viruses.

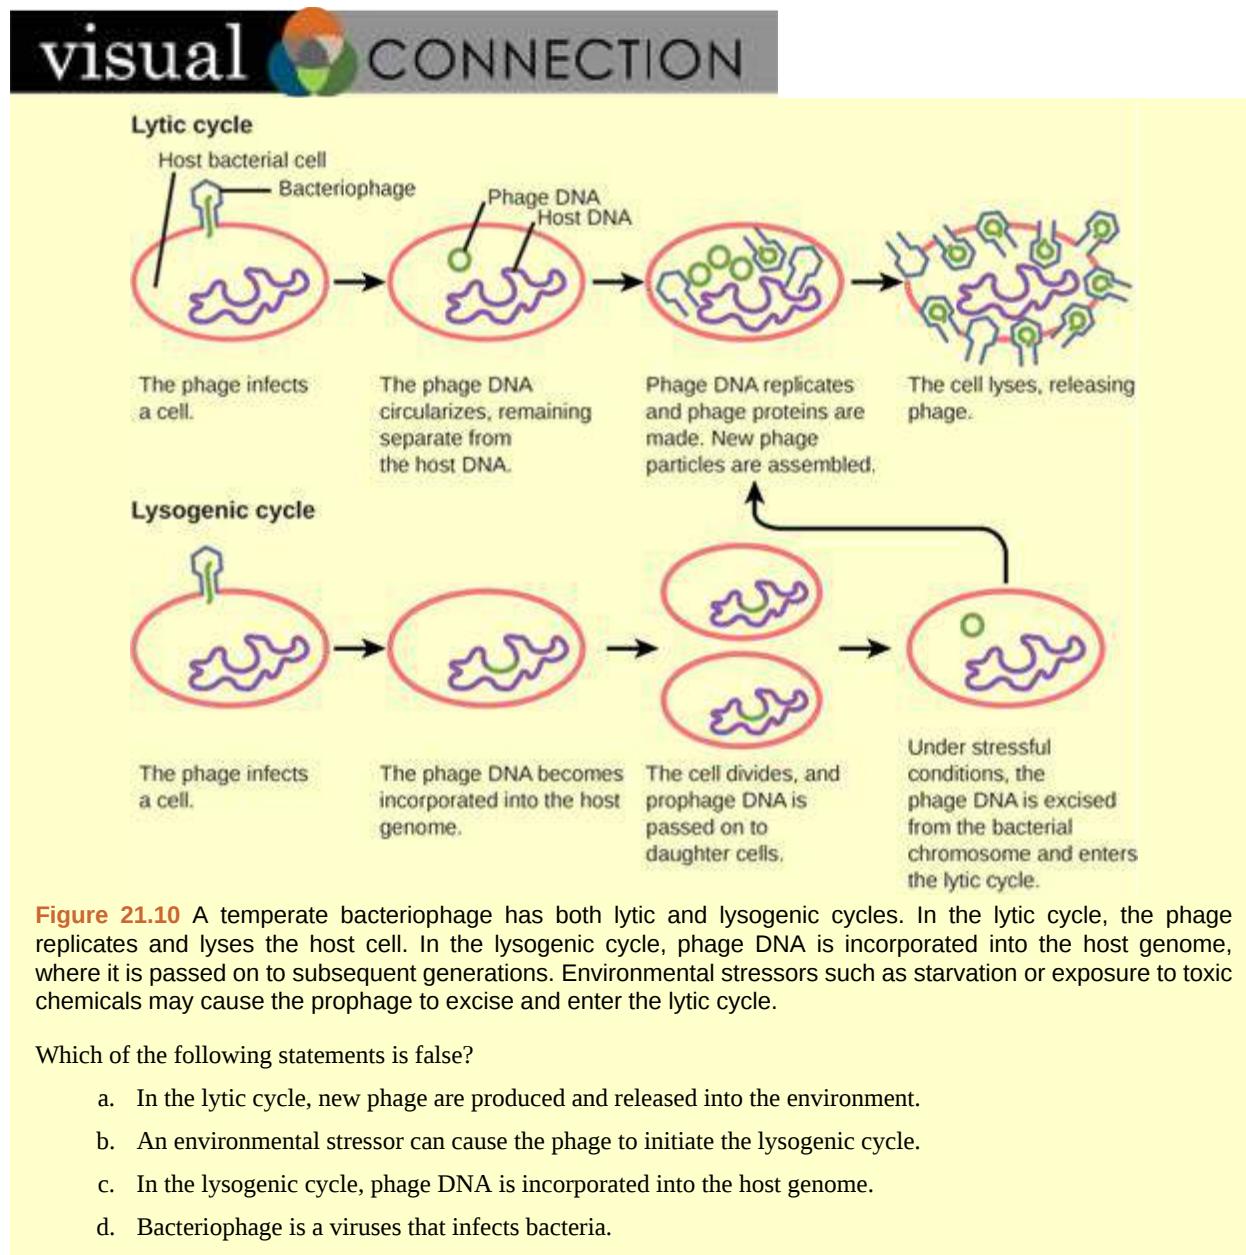

### Bacteriophages

**Figure 21.9** This transmission electron micrograph shows bacteriophages attached to a bacterial cell. (credit: modification of work by Dr. Graham Beards; scale-bar data from Matt Russell)

Bacteriophages are viruses that infect bacteria (Figure 21.9). When infection of a cell by a bacteriophage results in the production of new virions, the infection is said to be **productive**. If the virions are released by bursting the cell, the virus replicates by means of a lytic cycle (Figure 21.10). An example of a lytic bacteriophage is T4, which infects *Escherichia coli* found in the human intestinal tract. Sometimes, however, a virus can remain within the cell without being released. For example, when a temperate bacteriophage infects a bacterial cell, it replicates by means of a lysogenic cycle (Figure 21.10), and the viral genome is incorporated into the genome of the host cell. When the phage DNA is incorporated into the host cell genome, it is called a **prophage**. An example of a lysogenic bacteriophage is the λ (lambda) virus, which also infects

the *E. coli* bacterium. Viruses that infect plant or animal cells may also undergo infections where they are not producing virions for long periods. An example is the animal herpesviruses, including herpes simplex viruses, the cause of herpes in humans. In a process called **latency**, these viruses can exist in nervous tissue for long periods of time without producing new virions, only to leave latency periodically and cause lesions in the skin where the virus replicates. Even though there are similarities between lysogeny and latency, the term lysogenic cycle is usually reserved to describe bacteriophages. Latency will be described in more detail below.

**Figure 21.10** A temperate bacteriophage has both lytic and lysogenic cycles. In the lytic cycle, the phage replicates and lyses the host cell. In the lysogenic cycle, phage DNA is incorporated into the host genome, where it is passed on to subsequent generations. Environmental stressors such as starvation or exposure to toxic chemicals may cause the prophage to excise and enter the lytic cycle.

Which of the following statements is false?

- In the lytic cycle, new phage are produced and released into the environment.
- An environmental stressor can cause the phage to initiate the lysogenic cycle.
- In the lysogenic cycle, phage DNA is incorporated into the host genome.
- Bacteriophage is a viruses that infects bacteria.

## Animal Viruses

Animal viruses, unlike the viruses of plants and bacteria, do not have to penetrate a cell wall to gain access to the host cell. Non-enveloped or “naked” animal viruses may enter cells in two different ways. As a protein in the viral capsid binds to its receptor on the host cell, the virus may be taken inside the cell via a vesicle during the normal cell process of receptor-mediated endocytosis. An alternative method of cell penetration used by non-enveloped viruses is for capsid proteins to undergo shape changes after binding to the receptor, creating channels in the host cell membrane. The viral genome is then “injected” into the host cell through these channels in a manner analogous to that used by many bacteriophages. Enveloped

viruses also have two ways of entering cells after binding to their receptors: receptor-mediated endocytosis, or **fusion**. Many enveloped viruses enter the cell by receptor-mediated endocytosis in a fashion similar to some non-enveloped viruses. On the other hand, fusion only occurs with enveloped virions. These viruses, which include HIV among others, use special fusion proteins in their envelopes to cause the envelope to fuse with the plasma membrane of the cell, thus releasing the genome and capsid of the virus into the cell cytoplasm.

After making their proteins and copying their genomes, animal viruses complete the assembly of new virions and exit the cell. Enveloped animal viruses may bud from the cell membrane as they assemble themselves, taking a piece of the cell's plasma membrane in the process. On the other hand, non-enveloped viral progeny, such as rhinoviruses, accumulate in infected cells until there is a signal for lysis or apoptosis, and all virions are released together.

As you will learn in the next module, animal viruses are associated with a variety of human diseases. Some of them follow the classic pattern of **acute disease**, where symptoms get increasingly worse for a short period followed by the elimination of the virus from the body by the immune system and eventual recovery from the infection. Examples of acute viral diseases are the common cold and influenza. Other viruses cause long-term **chronic infections**, such as the virus causing hepatitis C, whereas others, like herpes simplex virus, only cause **intermittent** symptoms. Still other viruses, such as human herpesviruses 6 and 7, which in some cases can cause the minor childhood disease roseola, often successfully cause productive infections without causing any symptoms at all in the host, and thus we say these patients have an **asymptomatic infection**.

In hepatitis C infections, the virus grows and reproduces in liver cells, causing low levels of liver damage. The damage is so low that infected individuals are often unaware that they are infected, and many infections are detected only by routine blood work on patients with risk factors. On the other hand, since many of the symptoms of viral diseases are caused by immune responses, a lack of symptoms is an indication of a weak immune response to the virus. This allows for the virus to escape elimination by the immune system and persist in individuals for years, all the while producing low levels of progeny virions in what is known as a chronic viral disease.

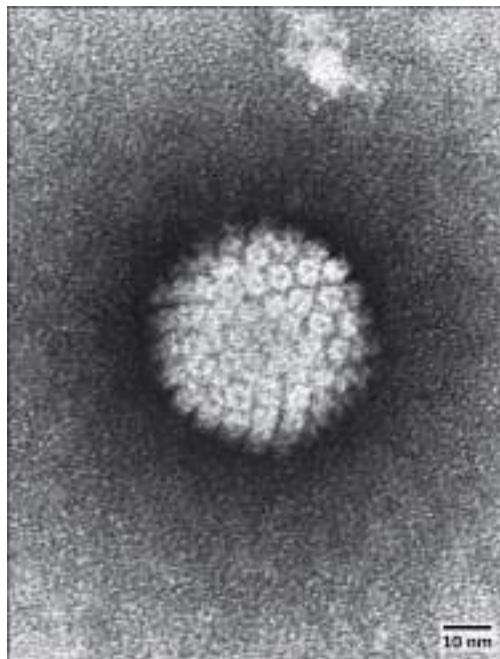

As already discussed, herpes simplex virus can remain in a state of latency in nervous tissue for months, even years. As the virus "hides" in the tissue and makes few if any viral proteins, there is nothing for the immune response to act against, and immunity to the virus slowly declines. Under certain conditions, including various types of physical and psychological stress, the latent herpes simplex virus may be reactivated and undergo a lytic replication cycle in the skin, causing the lesions associated with the disease. Once virions are produced in the skin and viral proteins are synthesized, the immune response is again stimulated and resolves the skin lesions in a few days by destroying viruses in the skin. As a result of this type of replicative cycle, appearances of cold sores outbreaks only occur intermittently, even though the viruses remain in the nervous tissue for life. Latent infections are common with other herpesviruses as well, including the varicella-zoster virus that causes chickenpox. After having a chickenpox infection in childhood, the varicella-zoster virus can remain latent for many years and reactivate in adults to cause the painful condition known as "shingles" (**Figure 21.11ab**).

**Figure 21.11** (a) Varicella-zoster, the virus that causes chickenpox, has an enveloped icosahedral capsid visible in this transmission electron micrograph. Its double-stranded DNA genome becomes incorporated in the host DNA and can reactivate after latency in the form of (b) shingles, often exhibiting a rash. (credit a: modification of work by Dr. Erskine Palmer, B. G. Martin, CDC; credit b: modification of work by "rosmary"/Flickr; scale-bar data from Matt Russell)

Some animal-infecting viruses, including the hepatitis C virus discussed above, are known as **oncogenic viruses**: They have the ability to cause cancer. These viruses interfere with the normal regulation of the host cell cycle either by either introducing genes that stimulate unregulated cell growth (oncogenes) or by interfering with the expression of genes that

inhibit cell growth. Oncogenic viruses can be either DNA or RNA viruses. Cancers known to be associated with viral infections include cervical cancer caused by human papillomavirus (HPV) (**Figure 21.12**), liver cancer caused by hepatitis B virus, T-cell leukemia, and several types of lymphoma.

**Figure 21.12** HPV, or human papillomavirus, has a naked icosahedral capsid visible in this transmission electron micrograph and a double-stranded DNA genome that is incorporated into the host DNA. The virus, is oncogenic and can lead to cervical cancer. (credit: modification of work by NCI, NIH; scale-bar data from Matt Russell)

Visit the interactive [animations](http://openstaxcollege.org/l/animal_viruses) ([http://openstaxcollege.org/l/animal\\_viruses](http://openstaxcollege.org/l/animal_viruses)) showing the various stages of the replicative cycles of animal viruses and click on the flash animation links.

Before a virus can replicate in a host cell, the capsid or envelope must be released. This process is sometimes referred to as \_\_\_\_\_.

- a. viral attachment or adsorption
- b. viral entry
- c. uncoating
- d. viral replication

## Plant Viruses

Plant viruses, like other viruses, contain a core of either DNA or RNA. You have already learned about one of these, the tobacco mosaic virus. As plant cells have a cell wall to protect their cells, these viruses do not use receptor-mediated endocytosis to enter host cells as is seen with animal viruses. For many plant viruses to be transferred from plant to plant, damage to some of the plants' cells must occur to allow the virus to enter a new host. This damage is often caused by weather, insects, animals, fire, or human activities like farming or landscaping. Additionally, plant offspring may inherit

viral diseases from parent plants. Plant viruses can be transmitted by a variety of vectors, through contact with an infected plant's sap, by living organisms such as insects and nematodes, and through pollen. When plants viruses are transferred between different plants, this is known as **horizontal transmission**, and when they are inherited from a parent, this is called **vertical transmission**.

Symptoms of viral diseases vary according to the virus and its host (Table 21.4). One common symptom is **hyperplasia**, the abnormal proliferation of cells that causes the appearance of plant tumors known as **galls**. Other viruses induce **hypoplasia**, or decreased cell growth, in the leaves of plants, causing thin, yellow areas to appear. Still other viruses affect the plant by directly killing plant cells, a process known as **cell necrosis**. Other symptoms of plant viruses include malformed leaves, black streaks on the stems of the plants, altered growth of stems, leaves, or fruits, and ring spots, which are circular or linear areas of discoloration found in a leaf.

### Some Common Symptoms of Plant Viral Diseases

| Symptom                  | Appears as                                                       |
|--------------------------|------------------------------------------------------------------|
| Hyperplasia              | Galls (tumors)                                                   |
| Hypoplasia               | Thinned, yellow splotches on leaves                              |
| Cell necrosis            | Dead, blackened stems, leaves, or fruit                          |
| Abnormal growth patterns | Malformed stems, leaves, or fruit                                |
| Discoloration            | Yellow, red, or black lines, or rings in stems, leaves, or fruit |

Table 21.4

Plant viruses can seriously disrupt crop growth and development, significantly affecting our food supply. They are responsible for poor crop quality and quantity globally, and can bring about huge economic losses annually. Others viruses may damage plants used in landscaping. Some viruses that infect agricultural food plants include the name of the plant they infect, such as tomato spotted wilt virus, bean common mosaic virus, and cucumber mosaic virus. In plants used for landscaping, two of the most common viruses are peony ring spot and rose mosaic virus. There are far too many plant viruses to discuss each in detail, but symptoms of bean common mosaic virus result in lowered bean production and stunted, unproductive plants. In the ornamental rose, the rose mosaic disease causes wavy yellow lines and colored splotches on the leaves of the plant.

## everyday CONNECTION for AP<sup>®</sup> Courses

Plant viruses can be spread through sap, insects, organisms living in the soil, seeds, and pollen. They cause damage to fruit, leaves, and stems, which has a large economic impact. For example, estimated yields from barley infected with the barley stripe mosaic virus as pictured below, can be 35–40% less. This virus is transmitted by a parasite that lives in the plant's roots.

**Figure 21.13** (credit: H.J. Larsen, Wikimedia Commons)

What symptoms of plant viral diseases do you see in this light micrograph of the cells of a plant root?

- a. hyperplasia
- b. abnormal growth patterns
- c. discoloration
- d. hypoplasia

## science practices CONNECTION for AP<sup>®</sup> Courses

### Activity

Create a visual representation to describe how viruses differ from bacteria in their modes of reproduction. What characteristics do viruses share with living organisms? How do they differ? What evidence supports the claim that viruses do not fit our usual definition of life?

### Think About It

The influenza virus that causes seasonal “flu” is packaged in a viral envelope that fuses with the plasma membrane. This way, the virus can exit the host cell without killing it. What advantage does the virus gain by keeping the host alive?

## 21.3 | Prevention and Treatment of Viral Infections

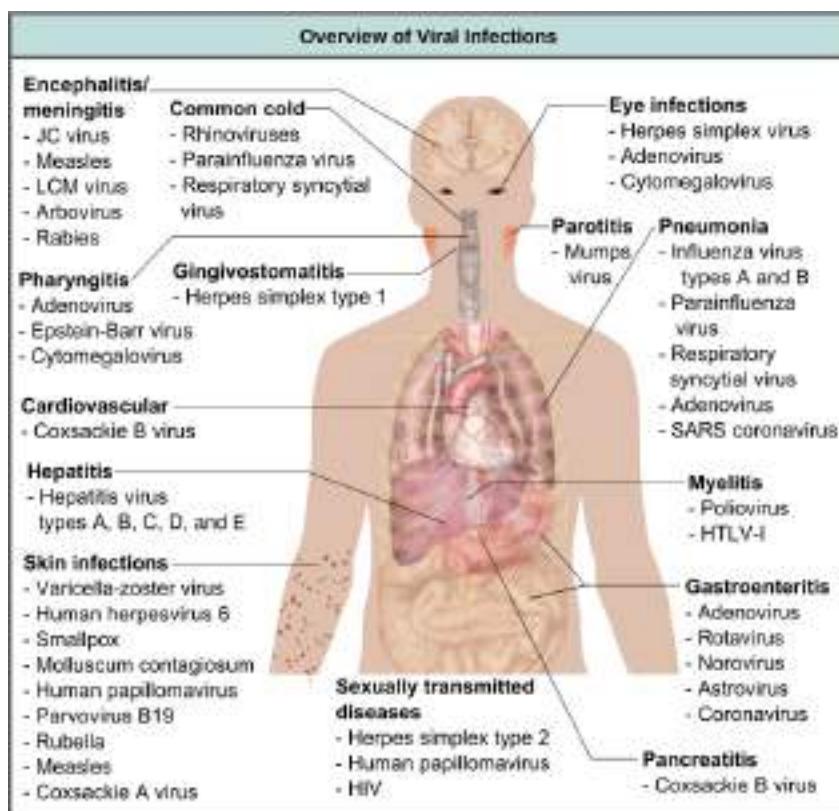

In this section, you will explore the following questions:

- What are examples of major viral illnesses that affect humans?
- How do vaccinations differ from antiviral drugs as medical approaches to viruses?

## Connection for AP® Courses

The majority of content described in this section is not within the scope for AP®. We explore some of these concepts when we study the immune system. However, because all of us will fight viral infections and will receive vaccinations against many diseases, including seasonal flu shots, the content in this section is relevant to our lives outside the classroom. While studying, think about why there are many different antibiotics available for treating bacterial infections but relatively few drugs available to treat viral infections. How do viruses differ from bacteria in both structure and activity?

Viruses cause a variety of diseases in animals, including humans, ranging from the common cold to potentially fatal illnesses like meningitis (Figure 21.14). These diseases can be treated by antiviral drugs or by vaccines, but some viruses are capable of both avoiding the immune response and mutating to become resistant to antiviral drugs.

**Figure 21.14** Viruses can cause dozens of ailments in humans, ranging from mild illnesses to serious diseases. (credit: modification of work by Mikael Häggström)

## Vaccines for Prevention

While we do have limited numbers of effective antiviral drugs, such as those used to treat influenza, the primary method of controlling viral disease is by vaccination, which is intended to prevent outbreaks by building immunity to a virus or virus family (Figure 21.15). **Vaccines** may be prepared using live viruses, killed viruses, or molecular subunits of the virus. The killed viral vaccines and subunit viruses are both incapable of causing disease.

Live viral vaccines are designed in the laboratory to cause few symptoms in recipients while giving them protective immunity against future infections. Polio was one disease that represented a milestone in the use of vaccines. Mass immunization campaigns in the 1950s (killed vaccine) and 1960s (live vaccine) significantly reduced the incidence of the disease, which caused muscle paralysis in children and generated a great amount of fear in the general population when regional epidemics occurred. The success of the polio vaccine paved the way for the routine dispensation of childhood vaccines against measles, mumps, rubella, chickenpox, and other diseases.

The danger of using live vaccines, which are usually more effective than killed vaccines, is the low but significant danger that these viruses will revert to their disease-causing form by **back mutations**. Live vaccines are usually made by **attenuating** (weakening) the “wild-type” (disease-causing) virus by growing it in the laboratory in tissues or at temperatures different from what the virus is accustomed to in the host. Adaptations to these new cells or temperatures induce mutations in the genomes of the virus, allowing it to grow better in the laboratory while inhibiting its ability to cause

disease when reintroduced into conditions found in the host. These attenuated viruses thus still cause infection, but they do not grow very well, allowing the immune response to develop in time to prevent major disease. Back mutations occur when the vaccine undergoes mutations in the host such that it readapts to the host and can again cause disease, which can then be spread to other humans in an epidemic. This type of scenario happened as recently as 2007 in Nigeria where mutations in a polio vaccine led to an epidemic of polio in that country.

Some vaccines are in continuous development because certain viruses, such as influenza, have a high mutation rate compared to other viruses and normal host cells. With influenza, mutations in the surface molecules of the virus help the organism evade the protective immunity that may have been obtained in a previous influenza season, making it necessary for individuals to get vaccinated every year. Other viruses, such as those that cause the childhood diseases measles, mumps, and rubella, mutate so infrequently that the same vaccine is used year after year.

**Figure 21.15** Vaccinations are designed to boost immunity to a virus to prevent infection. (credit: USACE Europe District)

Watch this NOVA video ([http://openstaxcollege.org/I/1918\\_flu](http://openstaxcollege.org/I/1918_flu)) to learn how microbiologists are attempting to replicate the deadly 1918 Spanish influenza virus so they can understand more about virology.

The Avian virus and the 1918 Spanish influenza virus both infect the \_\_\_\_\_ system.

- a. nervous
- b. respiratory
- c. cardio vascular
- d. digestive

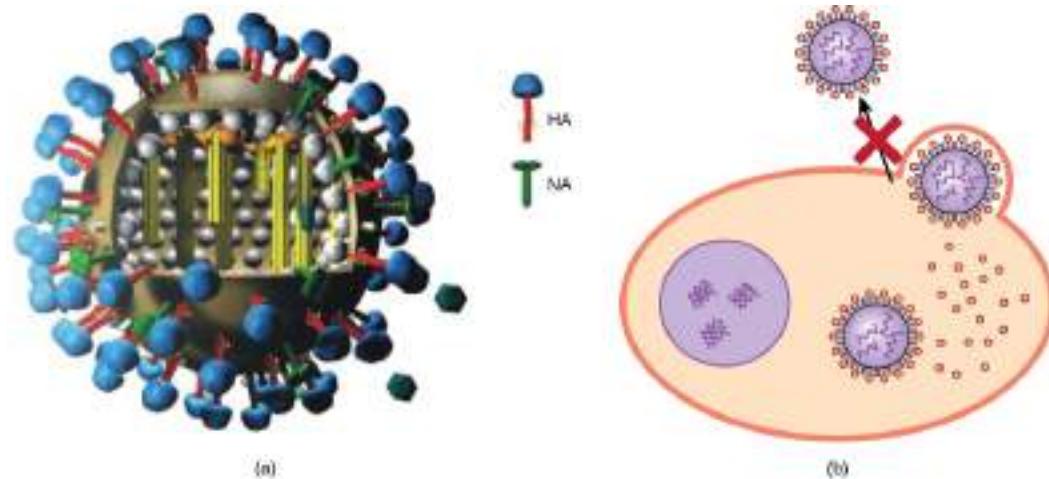

## Vaccines and Antiviral Drugs for Treatment

In some cases, vaccines can be used to treat an active viral infection. The concept behind this is that by giving the vaccine, immunity is boosted without adding more disease-causing virus. In the case of rabies, a fatal neurological disease transmitted via the saliva of rabies virus-infected animals, the progression of the disease from the time of the animal bite

to the time it enters the central nervous system may be 2 weeks or longer. This is enough time to vaccinate an individual who suspects that they have been bitten by a rabid animal, and their boosted immune response is sufficient to prevent the virus from entering nervous tissue. Thus, the potentially fatal neurological consequences of the disease are averted, and the individual only has to recover from the infected bite. This approach is also being used for the treatment of Ebola, one of the fastest and most deadly viruses on earth. Transmitted by bats and great apes, this disease can cause death in 70–90 percent of infected humans within 2 weeks. Using newly developed vaccines that boost the immune response in this way, there is hope that affected individuals will be better able to control the virus, potentially saving a greater percentage of infected persons from a rapid and very painful death.

Another way of treating viral infections is the use of antiviral drugs. These drugs often have limited success in curing viral disease, but in many cases, they have been used to control and reduce symptoms for a wide variety of viral diseases. For most viruses, these drugs can inhibit the virus by blocking the actions of one or more of its proteins. It is important that the targeted proteins be encoded by viral genes and that these molecules are not present in a healthy host cell. In this way, viral growth is inhibited without damaging the host. There are large numbers of antiviral drugs available to treat infections, some specific for a particular virus and others that can affect multiple viruses.

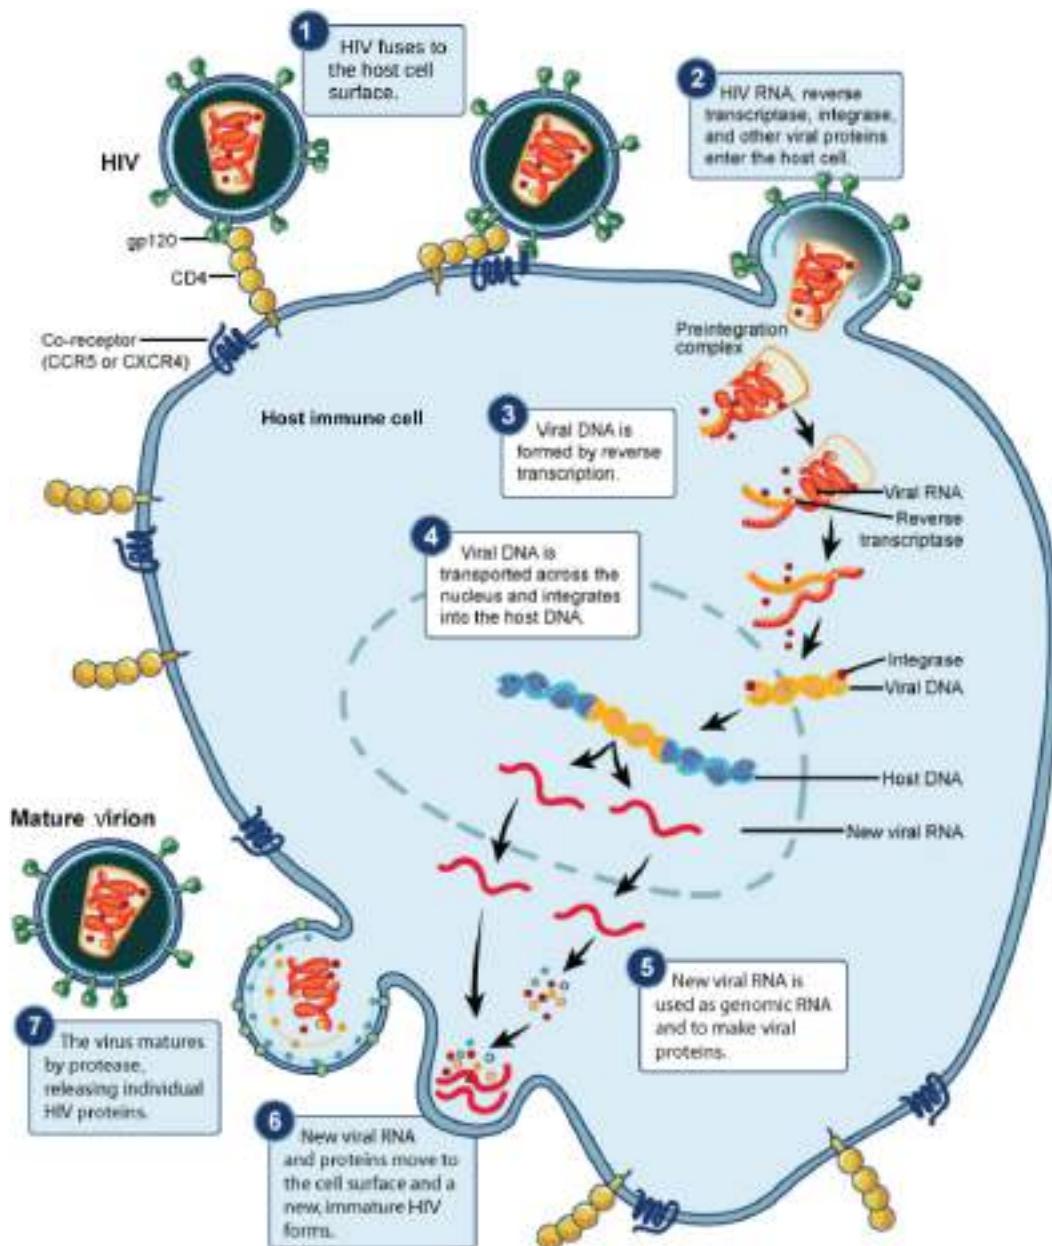

Antivirals have been developed to treat herpes and influenza. For herpes, drugs such as acyclovir can reduce the number and duration of episodes of active viral disease, during which patients develop viral lesions in their skin cells. As the virus remains latent in nervous tissue of the body for life, this drug is not curative but can make the symptoms of the disease more manageable. For influenza, drugs like oseltamivir (**Figure 21.16**) can reduce the duration of “flu” symptoms by 1 or 2 days, but the drug does not prevent symptoms entirely. Oseltamivir works by inhibiting an enzyme (viral neuraminidase) that allows new virions to leave their infected cells. Thus, Oseltamivir inhibits the spread of virus from infected to uninfected cells. Other antiviral drugs, such as Ribavirin, have been used to treat a variety of viral infections, although its mechanism of action against certain viruses remains unclear.

**Figure 21.16** (a) Oseltamivir inhibits a viral enzyme called neuraminidase (NA) found in the influenza viral envelope. (b) Neuraminidase cleaves the connection between viral hemagglutinin (HA), also found in the viral envelope, and glycoproteins on the host cell surface. Inhibition of neuraminidase prevents the virus from detaching from the host cell, thereby blocking further infection. (credit a: modification of work by M. Eickmann)

By far, the most successful use of antivirals has been in the treatment of the retrovirus HIV, which causes a disease that, if untreated, is usually fatal within 10–12 years after infection. Anti-HIV drugs have been able to control viral replication to the point that individuals receiving these drugs survive for a significantly longer time than the untreated.

Anti-HIV drugs inhibit viral replication at many different phases of the HIV replicative cycle (**Figure 21.17**). Drugs have been developed that inhibit the fusion of the HIV viral envelope with the plasma membrane of the host cell (fusion inhibitors), the conversion of its RNA genome into double-stranded DNA (reverse transcriptase inhibitors), the integration of the viral DNA into the host genome (integrase inhibitors), and the processing of viral proteins (protease inhibitors).

**Figure 21.17** HIV, an enveloped, icosahedral virus, attaches to the CD4 receptor of an immune cell and fuses with the cell membrane. Viral contents are released into the cell, where viral enzymes convert the single-stranded RNA genome into DNA and incorporate it into the host genome. (credit: NIAID, NIH)

When any of these drugs are used individually, the high mutation rate of the virus allows it to easily and rapidly develop resistance to the drug, limiting the drug's effectiveness. The breakthrough in the treatment of HIV was the development of HAART, highly active antiretroviral therapy, which involves a mixture of different drugs, sometimes called a drug "cocktail." By attacking the virus at different stages of its replicative cycle, it is much more difficult for the virus to develop resistance to multiple drugs at the same time. Still, even with the use of combination HAART therapy, there is concern that, over time, the virus will develop resistance to this therapy. Thus, new anti-HIV drugs are constantly being developed with the hope of continuing the battle against this highly fatal virus.

## everyday CONNECTION

### Applied Virology

The study of viruses has led to the development of a variety of new ways to treat non-viral diseases. Viruses have been used in **gene therapy**. Gene therapy is used to treat genetic diseases such as severe combined immunodeficiency (SCID), a heritable, recessive disease in which children are born with severely compromised immune systems. One common type of SCID is due to the lack of an enzyme, adenosine deaminase (ADA), which breaks down purine bases. To treat this disease by gene therapy, bone marrow cells are taken from a SCID patient and the ADA gene is inserted. This is where viruses come in, and their use relies on their ability to penetrate living cells and bring genes in with them. Viruses such as adenovirus, an upper respiratory human virus, are modified by the addition of the ADA gene, and the virus then transports this gene into the cell. The modified cells, now capable of making ADA, are then given back to the patients in the hope of curing them. Gene therapy using viruses as carrier of genes (viral vectors), although still experimental, holds promise for the treatment of many genetic diseases. Still, many technological problems need to be solved for this approach to be a viable method for treating genetic disease.

Another medical use for viruses relies on their specificity and ability to kill the cells they infect. **Oncolytic viruses** are engineered in the laboratory specifically to attack and kill cancer cells. A genetically modified adenovirus known as H101 has been used since 2005 in clinical trials in China to treat head and neck cancers. The results have been promising, with a greater short-term response rate to the combination of chemotherapy and viral therapy than to chemotherapy treatment alone. This ongoing research may herald the beginning of a new age of cancer therapy, where viruses are engineered to find and specifically kill cancer cells, regardless of where in the body they may have spread.

A third use of viruses in medicine relies on their specificity and involves using bacteriophages in the treatment of bacterial infections. Bacterial diseases have been treated with antibiotics since the 1940s. However, over time, many bacteria have developed resistance to antibiotics. A good example is methicillin-resistant *Staphylococcus aureus* (MRSA, pronounced “mersa”), an infection commonly acquired in hospitals. This bacterium is resistant to a variety of antibiotics, making it difficult to treat. The use of bacteriophages specific for such bacteria would bypass their resistance to antibiotics and specifically kill them. Although **phage therapy** is in use in the Republic of Georgia to treat antibiotic-resistant bacteria, its use to treat human diseases has not been approved in most countries. However, the safety of the treatment was confirmed in the United States when the U.S. Food and Drug Administration approved spraying meats with bacteriophages to destroy the food pathogen *Listeria*. As more and more antibiotic-resistant strains of bacteria evolve, the use of bacteriophages might be a potential solution to the problem, and the development of phage therapy is of much interest to researchers worldwide.

How can viruses be used in gene therapy?

- a. Viruses are used to attack and kill specific cells.
- b. Bacteriophages are used to treat bacterial infections.
- c. Viruses are used to transport a gene into a cell.
- d. Viruses are used to destroy the food pathogen Listeria.

### 21.4 | Other Acellular Entities: Prions and Viroids

In this section, you will explore the following questions:

- What are prions and how do they cause disease?
- What are viroids and their targets of infection?

## Connection for AP® Courses

The content described in this section is outside the scope for AP®. However, it's interesting to note that prions and viroids—pathogens that are far simpler in structure than viruses—can produce deadly diseases, including mad cow disease and Creutzfeldt–Jakob disease. Prions are infectious proteins, whereas viroids are single-stranded RNA **pathogens** (agents with the ability to cause disease) that infect plants.

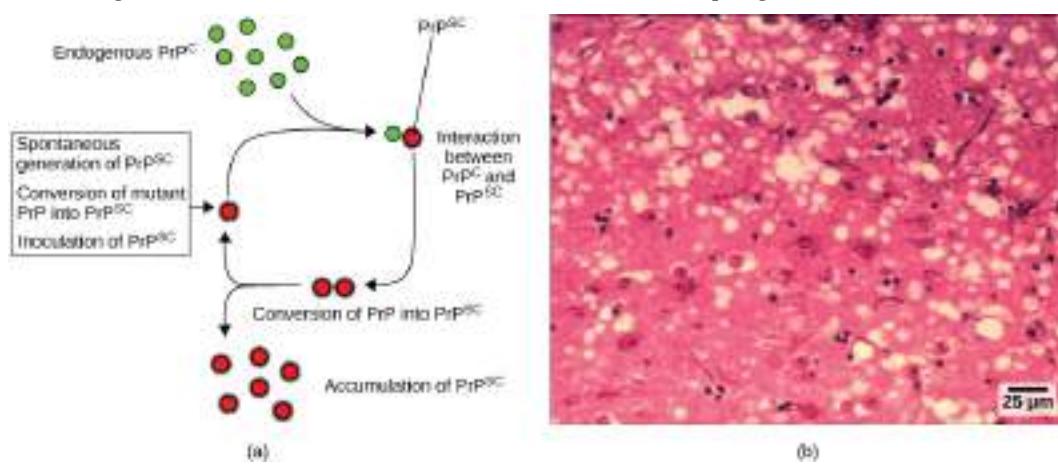

### Prions

**Prions**, so-called because they are proteinaceous, are infectious particles—smaller than viruses—that contain no nucleic acids (neither DNA nor RNA). Historically, the idea of an infectious agent that did not use nucleic acids was considered impossible, but pioneering work by Nobel Prize-winning biologist Stanley Prusiner has convinced the majority of biologists that such agents do indeed exist.

Fatal neurodegenerative diseases, such as kuru in humans and bovine spongiform encephalopathy (BSE) in cattle (commonly known as “mad cow disease”) were shown to be transmitted by prions. The disease was spread by the consumption of meat, nervous tissue, or internal organs between members of the same species. Kuru, native to humans in Papua New Guinea, was spread from human to human via ritualistic cannibalism. BSE, originally detected in the United Kingdom, was spread between cattle by the practice of including cattle nervous tissue in feed for other cattle. Individuals with kuru and BSE show symptoms of loss of motor control and unusual behaviors, such as uncontrolled bursts of laughter with kuru, followed by death. Kuru was controlled by inducing the population to abandon its ritualistic cannibalism.

On the other hand, BSE was initially thought to only affect cattle. Cattle dying of the disease were shown to have developed lesions or “holes” in the brain, causing the brain tissue to resemble a sponge. Later on in the outbreak, however, it was shown that a similar encephalopathy in humans known as variant Creutzfeldt-Jakob disease (CJD) could be acquired from eating beef from animals with BSE, sparking bans by various countries on the importation of British beef and causing considerable economic damage to the British beef industry (**Figure 21.18**). BSE still exists in various areas, and although a rare disease, individuals that acquire CJD are difficult to treat. The disease can be spread from human to human by blood, so many countries have banned blood donation from regions associated with BSE.

The cause of spongiform encephalopathies, such as kuru and BSE, is an infectious structural variant of a normal cellular protein called PrP (prion protein). It is this variant that constitutes the prion particle. PrP exists in two forms, **PrP<sup>C</sup>**, the normal form of the protein, and **PrP<sup>Sc</sup>**, the infectious form. Once introduced into the body, the **PrP<sup>Sc</sup>** contained within the prion binds to **PrP<sup>C</sup>** and converts it to **PrP<sup>Sc</sup>**. This leads to an exponential increase of the **PrP<sup>Sc</sup>** protein, which aggregates. **PrP<sup>Sc</sup>** is folded abnormally, and the resulting conformation (shape) is directly responsible for the lesions seen in the brains of infected cattle. Thus, although not without some detractors among scientists, the prion seems likely to be an entirely new form of infectious agent, the first one found whose transmission is not reliant upon genes made of DNA or RNA.

**Figure 21.18** (a) Endogenous normal prion protein (PrP<sup>C</sup>) is converted into the disease-causing form (PrP<sup>Sc</sup>) when it encounters this variant form of the protein. PrP<sup>Sc</sup> may arise spontaneously in brain tissue, especially if a mutant form of the protein is present, or it may occur via the spread of misfolded prions consumed in food into brain tissue. (b) This prion-infected brain tissue, visualized using light microscopy, shows the vacuoles that give it a spongy texture, typical of transmissible spongiform encephalopathies. (credit b: modification of work by Dr. Al Jenny, USDA APHIS; scale-bar data from Matt Russell)

## Viroids

**Viroids** are plant pathogens: small, single-stranded, circular RNA particles that are much simpler than a virus. They do not have a capsid or outer envelope, but like viruses can reproduce only within a host cell. Viroids do not, however, manufacture any proteins, and they only produce a single, specific RNA molecule. Human diseases caused by viroids have yet to be identified.

Viroids are known to infect plants (**Figure 21.19**) and are responsible for crop failures and the loss of millions of dollars in agricultural revenue each year. Some of the plants they infect include potatoes, cucumbers, tomatoes, chrysanthemums, avocados, and coconut palms.

**Figure 21.19** These potatoes have been infected by the potato spindle tuber viroid (PSTV), which is typically spread when infected knives are used to cut healthy potatoes, which are then planted. (credit: Pamela Roberts, University of Florida Institute of Food and Agricultural Sciences, USDA ARS)

## career CONNECTION

### Virologist

Virology is the study of viruses, and a virologist is an individual trained in this discipline. Training in virology can lead to many different career paths. Virologists are actively involved in academic research and teaching in colleges and medical schools. Some virologists treat patients or are involved in the generation and production of vaccines. They might participate in epidemiologic studies (**Figure 21.20**) or become science writers, to name just a few possible careers.

**Figure 21.20** This virologist is engaged in fieldwork, sampling eggs from this nest for avian influenza. (credit: Don Becker, USGS EROS, U.S. Fish and Wildlife Service)

If you think you may be interested in a career in virology, find a mentor in the field. Many large medical centers have departments of virology, and smaller hospitals usually have virology labs within their microbiology departments. Volunteer in a virology lab for a semester or work in one over the summer. Discussing the profession and getting a first-hand look at the work will help you decide whether a career in virology is right for you. The American Society of Virology's [website \(<http://openstaxcollege.org/l/asv>\)](http://openstaxcollege.org/l/asv) is a good resource for information regarding training and careers in virology.

## KEY TERMS

**acellular** lacking cells

**acute disease** disease where the symptoms rise and fall within a short period of time

**asymptomatic disease** disease where there are no symptoms and the individual is unaware of being infected unless lab tests are performed

**attenuation** weakening of a virus during vaccine development

**AZT** anti-HIV drug that inhibits the viral enzyme reverse transcriptase

**back mutation** when a live virus vaccine reverts back to its disease-causing phenotype

**bacteriophage** virus that infects bacteria

**budding** method of exit from the cell used in certain animal viruses, where virions leave the cell individually by capturing a piece of the host plasma membrane

**capsid** protein coating of the viral core

**capsomere** protein subunit that makes up the capsid

**cell necrosis** cell death

**chronic infection** describes when the virus persists in the body for a long period of time

**cytopathic** causing cell damage

**envelope** lipid bilayer that envelopes some viruses

**fusion** method of entry by some enveloped viruses, where the viral envelope fuses with the plasma membrane of the host cell

**gall** appearance of a plant tumor

**gene therapy** treatment of genetic disease by adding genes, using viruses to carry the new genes inside the cell

**group I virus** virus with a dsDNA genome

**group II virus** virus with a ssDNA genome

**group III virus** virus with a dsRNA genome

**group IV virus** virus with a ssRNA genome with positive polarity

**group V virus** virus with a ssRNA genome with negative polarity

**group VI virus** virus with ssRNA genomes converted into dsDNA by reverse transcriptase

**group VII virus** virus with a single-stranded mRNA converted into dsDNA for genome replication

**horizontal transmission** transmission of a disease from parent to offspring

**hyperplasia** abnormally high cell growth and division

**hypoplasia** abnormally low cell growth and division

**intermittent symptom** symptom that occurs periodically

**latency** virus that remains in the body for a long period of time but only causes intermittent symptoms

**lysis** bursting of a cell

**lysogenic cycle** type of virus replication in which the viral genome is incorporated into the genome of the host cell

**lytic cycle** type of virus replication in which virions are released through lysis, or bursting, of the cell

**matrix protein** envelope protein that stabilizes the envelope and often plays a role in the assembly of progeny virions

**negative polarity** ssRNA viruses with genomes complementary to their mRNA

**oncogenic virus** virus that has the ability to cause cancer

**oncolytic virus** virus engineered to specifically infect and kill cancer cells

**pathogen** agent with the ability to cause disease

**permissive** cell type that is able to support productive replication of a virus

**phage therapy** treatment of bacterial diseases using bacteriophages specific to a particular bacterium

**positive polarity** ssRNA virus with a genome that contains the same base sequences and codons found in their mRNA

**prion** infectious particle that consists of proteins that replicate without DNA or RNA

**productive** viral infection that leads to the production of new virions

**prophage** phage DNA that is incorporated into the host cell genome

**PrP<sup>c</sup>** normal prion protein

**PrP<sup>sc</sup>** infectious form of a prion protein

**replicative intermediate** dsRNA intermediate made in the process of copying genomic RNA

**retrovirus** virus with an RNA genome that must be reverse transcribed into DNA before being incorporated into the host cell genome

**reverse transcriptase** enzyme found in Baltimore groups VI and VII that converts single-stranded RNA into double-stranded DNA

**vaccine** weakened solution of virus components, viruses, or other agents that produce an immune response

**vertical transmission** transmission of disease from parent to offspring

**viral receptor** glycoprotein used to attach a virus to host cells via molecules on the cell

**virion** individual virus particle outside a host cell

**viroid** plant pathogen that produces only a single, specific RNA

**virus core** contains the virus genome

## CHAPTER SUMMARY

### 21.1 Viral Evolution, Morphology, and Classification

Viruses are tiny, acellular entities that can usually only be seen with an electron microscope. Their genomes contain either DNA or RNA—never both—and they replicate using the replication proteins of a host cell. Viruses are diverse, infecting archaea, bacteria, fungi, plants, and animals. Viruses consist of a nucleic acid core surrounded by a protein capsid with or without an outer lipid envelope. The capsid shape, presence of an envelope, and core composition dictate some elements of the classification of viruses. The most commonly used classification method, the Baltimore classification, categorizes viruses based on how they produce their mRNA.

## 21.2 Virus Infection and Hosts

Viral replication within a living cell always produces changes in the cell, sometimes resulting in cell death and sometimes slowly killing the infected cells. There are six basic stages in the virus replication cycle: attachment, penetration, uncoating, replication, assembly, and release. A viral infection may be productive, resulting in new virions, or nonproductive, which means that the virus remains inside the cell without producing new virions. Bacteriophages are viruses that infect bacteria. They have two different modes of replication: the lytic cycle, where the virus replicates and bursts out of the bacteria, and the lysogenic cycle, which involves the incorporation of the viral genome into the bacterial host genome. Animal viruses cause a variety of infections, with some causing chronic symptoms (hepatitis C), some intermittent symptoms (latent viruses such as herpes simplex virus 1), and others that cause very few symptoms, if any (human herpesviruses 6 and 7). Oncogenic viruses in animals have the ability to cause cancer by interfering with the regulation of the host cell cycle. Viruses of plants are responsible for significant economic damage in both agriculture and plants used for ornamentation.

## 21.3 Prevention and Treatment of Viral Infections

Viruses cause a variety of diseases in humans. Many of these diseases can be prevented by the use of viral vaccines, which stimulate protective immunity against the virus without causing major disease. Viral vaccines may also be used in active viral infections, boosting the ability of the immune system to control or destroy the virus. A series of antiviral drugs that target enzymes and other protein products of viral genes have been developed and used with mixed success. Combinations of anti-HIV drugs have been used to effectively control the virus, extending the lifespans of infected individuals. Viruses have many uses in medicines, such as in the treatment of genetic disorders, cancer, and bacterial infections.

## 21.4 Other Acellular Entities: Prions and Viroids

Prions are infectious agents that consist of protein, but no DNA or RNA, and seem to produce their deadly effects by duplicating their shapes and accumulating in tissues. They are thought to contribute to several progressive brain disorders, including mad cow disease and Creutzfeldt-Jakob disease. Viroids are single-stranded RNA pathogens that infect plants. Their presence can have a severe impact on the agriculture industry.

## REVIEW QUESTIONS

1. Viruses were first discovered after the development of the porcelain filter, called the Chamberland-Pasteur filter. How did the porcelain filter enable scientists to discover viruses?

- a. The porcelain filter removed diseases from a liquid sample.
- b. The porcelain filter removed virions from a liquid sample.
- c. The porcelain filter removed bacteria from a liquid sample.
- d. The porcelain filter removed a disease from tobacco plants.

2. In the late 1930s, scientists got their first good view of viruses. How did this happen?

- a. The development of the light microscope helped scientists discover many viruses of all types of living organisms.
- b. The development of the viral receptor helped scientists discover many viruses of all types of living organisms.
- c. The development of the porcelain filter helped scientists discover many viruses of all types of living organisms.
- d. The development of the electron microscope helped scientists discover many viruses of all types of living organisms.

3. Determining the origins of viruses is challenging. The \_\_\_\_\_ hypothesis proposes to explain the origin of viruses by suggesting that viruses evolved from free-living cells.

- a. escapist or the progressive
- b. system of self-replication
- c. devolution or the regressive
- d. virus molecular systematics

4. Which statement best describes what biologists know about the evolution of viruses?

- a. Scientists can look at fossil records and similar historic evidence.
- b. Much about virus origins and evolution remains unknown.
- c. Biologists have accumulated a significant amount of knowledge about how viruses originated.
- d. Biologists know exactly when viruses emerged and from where they came.
- 5.** A(n) \_\_\_\_\_ is an individual virus particle outside a host cell that consists of a nucleic acid core, an outer protein coating, and sometimes an outer envelope.
- capsid
  - virion
  - capsomere
  - viral receptor
- 6.** For many viruses to penetrate the cell membrane and complete their replication inside the cell, the virus must attach to their host cells. Describe how a virus attaches to a host cell.
- A virus uses its cellular structure to attach to a host cell.
  - A virus uses a plasma membrane to connect to a host cell.
  - A virus uses matrix proteins to attach to a host cell.
  - Viruses use viral receptors to attach to a host cell.
- 7.** \_\_\_\_\_ means that the genomic RNA can function as mRNA.
- double-stranded
  - negative polarity
  - positive polarity
  - replica intermediates
- 8.** Viruses are often classified based on the type of genetic material and its structure. In the Baltimore classification scheme, the \_\_\_\_\_ virus has a single-stranded RNA (-) genome.
- human immunodeficiency virus (HIV)
  - rabies (rhabdovirus)
  - canine parvovirus (parvovirus)
  - common cold (picornavirus)
- 9.** To get a visual look at the internal structure of virions, scientists must use a(n) \_\_\_\_\_.
- a. scanning electron microscope
- b. transmission electron microscope
- c. porcelain filter
- d. light microscope
- 10.** Which of the following statements about the viral replication cycle is accurate?
- The viral replication cycle does not affect the structure of the host cell.
  - The viral replication cycle cannot affect genetic material of the host cell.
  - The viral replication cycle has seven basic steps.
  - The viral replication cycle can change cell functions or even destroy the host cell.
- 11.** What happens in the replication cycle?
- During the budding process, virions leave the host cell individually
  - During the budding process, the host cell bursts.
  - During the budding process, the virus connects with a permissive host cell.
  - During the budding process, the host cell dies immediately.
- 12.** In the \_\_\_\_\_ cycle, the virus replicates and bursts out of the host cell.
- lytic
  - lysogenic
  - cytopathic
  - latency
- 13.** How is the lytic cycle different from the lysogenic cycle?
- The phage infects a cell in the lytic cycle.
  - The lytic cycle contains the formation of a prophage.
  - In the lytic cycle, new phages are produced; immediately in the lysogenic cycle phage DNA is merged into the host genome.
  - The phages move on to infect other cells in the lysogenic phase.
- 14.** Which of the following statements is false?

- a. Enveloped viruses and naked viruses both may enter cells using the fusion method.
- b. Many enveloped viruses enter the cell by receptor-mediated endocytosis.
- c. Naked viruses enter the cell by receptor-mediated endocytosis.
- d. Undergoing shape changes and creating channels in the host cell membrane is an alternative method of cell penetration used by naked viruses.
- 15.** An apple tree has yellow splotches on the leaves. This is a symptom of \_\_\_\_\_.  
a. cell necrosis  
b. discoloration  
c. hyperplasia  
d. hypoplasia
- 16.** What happens during the release step in the viral replication cycle?  
a. During the release step, genetic information is transferred through the lytic and lysogenic cycles.  
b. During the release step, DNA is transcribed to messenger RNA.  
c. During the release step, the nucleic acid is released from the viral capsid or envelope.  
d. During the release step, the new virions are able to infect adjacent cells and repeat the replication cycle.
- 17.** Why does the HIV virus use reverse transcriptase in the replication process?  
a. The HIV virus uses reverse transcriptase to replicate cells and build proteins.  
b. The HIV virus uses reverse transcriptase to erase mutated virions.  
c. The HIV virus uses reverse transcriptase because it is a retrovirus.  
d. The HIV virus uses reverse transcriptase because it has a DNA genome.
- 18.** What are the symptoms of the herpes simplex virus?  
a. The herpes simplex virus causes eye infections.  
b. The herpes simplex virus causes pneumonia.  
c. The herpes simplex virus causes pancreatitis.  
d. The herpes simplex virus can cause septicemia.
- 19.** Which of the following statements accurately describes the measles virus?  
a. The measles virus causes nasal and lung infections.  
b. The measles virus causes pancreas and liver infections.  
c. The measles virus causes mouth and gum infections.  
d. The measles virus causes brain and skin infections.
- 20.** Which of the following statements best describes vaccines?  
a. Vaccines kill viruses.  
b. Vaccines stimulate an immune response against future infections.  
c. Vaccines inhibit the virus by blocking the action of key viral proteins.  
d. Vaccines control and reduce symptoms.
- 21.** Which kind of therapy attacks a stage of the virus replicative cycle?  
a. phage therapy  
b. anti-retroviral  
c. gene therapy  
d. cancer therapy
- 22.** Which virus causes parotitis?  
a. measles virus  
b. norovirus  
c. HIV  
d. mumps virus
- 23.** Which of the following statements about prions is true?  
a. Prions are larger than viruses.  
b. Prions contain DNA and RNA.  
c. The PrPC<sup>s</sup> is the normal form of the protein.  
d. The PrPSC<sup>s</sup> folded abnormally.
- 24.** Kuru is a prion disease that affects both humans and animals. How is Kuru spread?  
a. Kuru disease is spread between cattle.  
b. Kuru is passed from person to person.  
c. Kuru is passed from cows with BSE to humans.  
d. Kuru is a viroid that infects plants.
- 25.** Which of the following statements about viroids is true?  
a. Viroids are single-stranded RNA particles.  
b. Viroids reproduce only outside of the cell.  
c. Viroids produce proteins.  
d. Viroids affect both plants and animals.

**26.** On which industry can viroids have a severe impact?

- a. dairy
- b. poultry
- c. avocado
- d. livestock

**27.** Which of the following statements best explains how infected prions cause disease?

- a. Infected prions cause disease by transmitting nucleic acids to normal prion proteins.
- b. Infected prions cause disease by converting DNA to RNA in normal prion proteins.
- c. Infected prions cause disease by converting the shapes of normal proteins.
- d. Infected prions cause disease by replicating the normal form of the protein.

## CRITICAL THINKING QUESTIONS

**28.** How did the development of a porcelain filter, called the Chamberland-Pasteur filter, help scientists discover viruses?

- a. After filtering a liquid plant extract, the scientists could see the virions using the light microscope.
- b. After filtering a liquid plant extract, the disease was still transferred to a healthy plant.
- c. After filtering a liquid plant extract, the virus cells multiplied.
- d. After filtering a liquid plant extract, scientists were able to trace historical footprints.

**29.** Scientists have a few hypotheses about virus origins. Why might they develop and refine further hypotheses to explain the origin of viruses?

- a. Advances in technology provide historic evidence.
- b. Biochemical and genetic information provide historic evidence.
- c. Advances in technology provide new information for scientists.
- d. Advances in technology have proven that viruses have a single common ancestor.

**30.** Why don't dogs catch the measles?

- a. Measles is a DNA virus, and DNA viruses cause human diseases.
- b. Dogs do not have glycoproteins.
- c. The virus can't attach to dog cells.
- d. Dogs do not get RNA viruses.

**31.** The Baltimore classification system groups viruses according to how the mRNA is produced. When classified this way, the viruses in each group \_\_\_\_\_.

- a. behave in a similar manner
- b. look very similar
- c. connect with living things
- d. are based on the type of disease they cause

**32.** Researchers have been able to develop a variety of anti-HIV drugs, such as the drug AZT. How does the drug

AZT work?

- a. AZT blocks the enzyme called HIV protease, which the virus uses to reproduce itself.
- b. AZT blocks the HIV integrase enzyme, which the virus uses to insert its viral DNA into the DNA of the host cell.
- c. AZT prevents reverse transcriptase and HIV protease enzyme from functioning inside the body.
- d. AZT prevents reverse transcriptase from making DNA from the viral RNA genome.

**33.** Compare the lytic and lysogenic cycles and explain which cycle has the potential to produce the most virions.

- a. The lytic cycle can theoretically produce more virions as the viral genome is incorporated into the host cell's genome replicating along with the host cell.
- b. The lysogenic cycle can theoretically produce more virions as the reproductive cycle of viruses undergoing lysogeny is much faster than the reproductive cycle of viruses following lytic cycle.
- c. The lysogenic cycle can theoretically produce more virions as the viral genome is incorporated into the host cell's genome replicating along with the host cell.
- d. The lytic cycle can theoretically produce more virions as the prophage following lysogenic cycle ultimately gets excised from the host cell's genome and enter the lytic cycle.

**34.** Would a person who has never been in contact with the varicella-zoster virus be at risk of developing chickenpox or shingles if they come in close contact with a person with shingles? Explain your reasoning.

- a. The person is at risk of developing chickenpox. Chickenpox is the first infection with the virus before it enters latency in the host.
- b. The person is at risk of developing shingles. Shingles is the first infection with the virus before it enters latency in the host.
- c. The person is at risk of developing chickenpox. Chickenpox is the first infection with the virus that is already latent in the body.
- d. The person is at risk of developing shingles. The virus enters the person and gets activated when a person with shingles comes in close contact.

**35.** Which step in the replication cycle of viruses do you think is most critical for the virus to infect cells? Explain why.

- a. The attachment step is the most critical, as infection cannot begin if virus does not attach to the host cell.
- b. The replication step is the most critical as this step directs protein synthesis.
- c. The assembly step is the most critical because new virions are assembled to infect cells.
- d. The entry step is the most critical as nucleic acid of virus needs to enter the host cell naked, leaving the capsid outside.

**36.** For most people, the measles virus does not cause a serious illness. Symptoms include fever and a rash, but the symptoms are usually gone in about a week. However, for some, the measles virus can be much more serious. How can the measles virus cause a potentially fatal illness?

- a. Measles can cause meningococcal disease, which causes severe headaches, seizures and in severe cases can be life-threatening.
- b. Measles can cause variant Creutzfeldt–Jakob disease, which causes severe headaches, seizures and in severe cases can be life-threatening.
- c. Measles can cause encephalitis/meningitis, which causes severe headaches, seizures and in severe cases can be life-threatening.
- d. Measles can cause Legionnaires' disease, which causes severe headaches, seizures and in severe cases can be life-threatening.

**37.** Why is immunization after being bitten by a rabid animal so effective and why aren't people vaccinated for rabies like dogs and cats are?

- a. It takes a month for the virus to travel from the site of the bite to the central nervous system. People are not vaccinated beforehand as routine vaccination of domestic animals makes it unlikely that humans will contract rabies from an animal bite.
- b. It takes a week for the virus to travel from the site of the bite to the peripheral nervous system. People are not vaccinated beforehand as routine vaccination of domestic animals makes it unlikely that humans will contract rabies from an animal bite.
- c. It takes a week for the virus to travel from the site of the bite to the central nervous system. People are not vaccinated beforehand as routine vaccination of domestic animals makes it unlikely that humans will contract rabies from an animal bite, and also.
- d. It takes a week for the virus to travel from the site of the bite to the central nervous system. People are not vaccinated beforehand, as routine vaccination of domestic animals makes it fully sure that humans will contract rabies from an animal bite, and also.

**38.** Why don't dogs and cats catch human colds from humans?

- a. As cats and dogs have different proteins than humans, the virus that causes colds in humans cannot find receptors in dogs and cats.
- b. As cats and dogs have different receptors than humans, the virus that causes colds in humans cannot find receptors in dogs and cats.
- c. As cats and dogs' immune system attacks the virus unlike humans, so the virus that causes colds in humans cannot find receptors in dogs and cats.
- d. As natural killer cells of cats and dogs attack the virus, the virus that causes colds in humans cannot find receptors in dogs and cats.

**39.** Prions are responsible for variant CJD (Creutzfeldt Jakob Disease). How has this disease been documented to spread from human to human?

- a. Surgery with instruments previously used in a patient with vCJD that were not adequately sterilized and contaminated pineal growth hormones taken from human pineal glands from infected cadavers.
- b. Through human consumption of infected meat and contaminated pituitary growth hormones taken from human pituitary glands from infected cadavers.
- c. Surgery with instruments previously used in a patient with vCJD that were not adequately sterilized and contaminated pituitary growth hormones taken from human pituitary glands from unwell individuals.
- d. Surgery with instruments previously used in a patient with vCJD that were not adequately sterilized and contaminated pituitary growth hormones taken from human pituitary glands from infected cadavers.
40. What characteristics do viroids and viruses have in

common?

- a. They both replicate within a host cell and contain nucleic acids.
- b. They both replicate within a host cell and do not contain nucleic acids.
- c. They both replicate within a host cell and contain proteins.
- d. They both replicate within a host cell and contain only RNA.

41. Why is the transmission of a prion not reliant upon genes made of DNA or RNA?

- a. DNA or RNA, though present, is not transmitted when a prion causes infection.
- b. The prion does not contain DNA or RNA.
- c. Only parts of DNA or RNA are transmitted in a prion.
- d. More of protein and less of DNA or RNA is transmitted.

## TEST PREP FOR AP® COURSES

42. The table below shows the Baltimore Classification used to classify viruses based on their genetic material. What is the difference between how Group I and Group III viruses reproduce?

| Baltimore classification |                                                |
|--------------------------|------------------------------------------------|
| Group                    | Characteristics                                |
| I                        | Double-stranded DNA                            |
| II                       | Single-stranded DNA                            |
| III                      | Double-stranded RNA                            |
| IV                       | Single-stranded RNA (+)                        |
| V                        | Single-stranded RNA (-)                        |
| VI                       | Single-stranded RNA with reverse transcriptase |
| VII                      | Double-stranded DNA with reverse transcriptase |

- a. In Group I, RNA is transcribed from an RNA genome while in Group III, RNA is transcribed from a DNA genome.
- b. In Group I, RNA is transcribed from a DNA genome while in Group III, RNA is transcribed from an RNA genome.
- c. In Group I, DNA is transcribed from a DNA genome while in Group III, RNA is transcribed from an RNA genome.
- d. In Group I, DNA is transcribed from an RNA genome while in Group III, RNA is transcribed from a DNA genome.

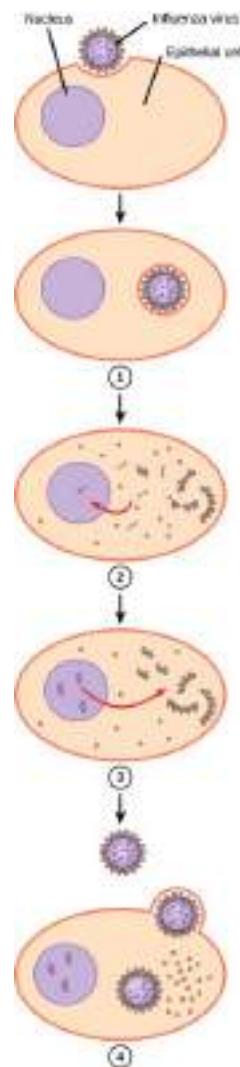

43. The table below shows the Baltimore Classification used to classify viruses based on their genetic material. What is a similar or different between the genome of Group I and Group VI, as well as how the two virus types reproduce?

| Baltimore classification |                                                |
|--------------------------|------------------------------------------------|
| Group                    | Characteristics                                |
| I                        | Double-stranded DNA                            |
| II                       | Single-stranded DNA                            |
| III                      | Double-stranded RNA                            |
| IV                       | Single-stranded RNA (+)                        |
| V                        | Single-stranded RNA (-)                        |
| VI                       | Single-stranded RNA with reverse transcriptase |
| VII                      | Double-stranded DNA with reverse transcriptase |

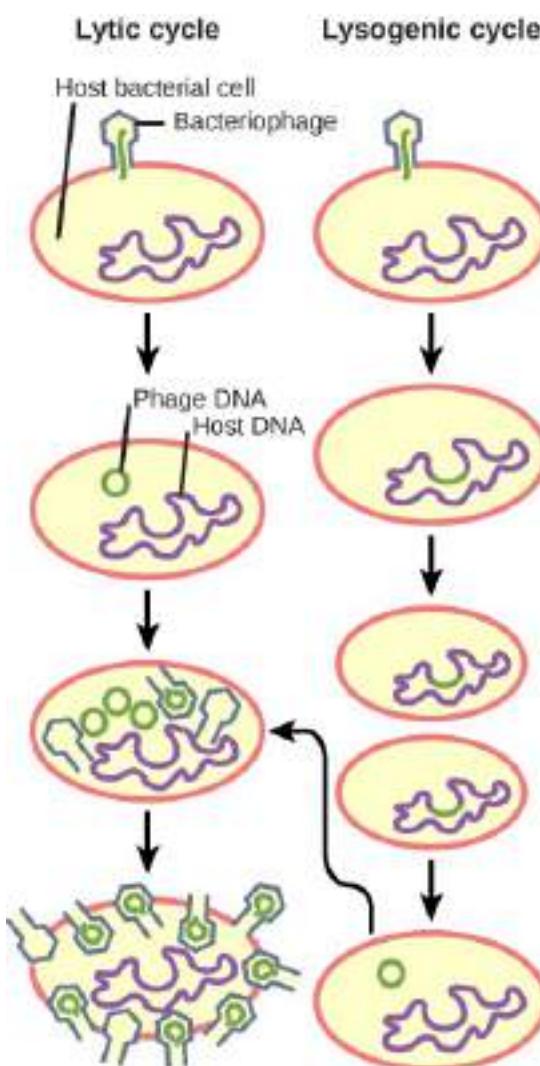

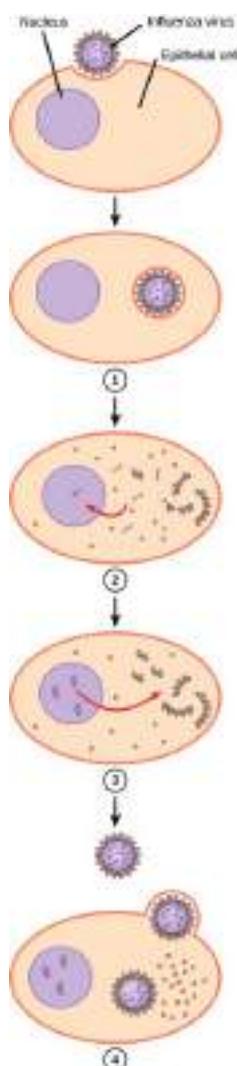

- a. Group I and VI viruses use RNA as their genome. Group I viruses reproduce by transcribing RNA from their DNA genome, while Group VI viruses first synthesize their RNA genome using reverse transcriptase before they can reproduce.
- b. Group I and VI viruses use DNA as their genome. Group I viruses reproduce by transcribing RNA from their DNA genome while group VI viruses first synthesize their DNA genome using reverse transcriptase before they can reproduce.
- c. Group I and VI viruses use DNA as their genome. Group I viruses reproduce by transcribing RNA from their DNA genome, while group VI viruses first synthesize RNA genome using reverse transcriptase before they can reproduce.
- d. Group I viruses use DNA as their genome while group VI use RNA. Group I viruses reproduce by transcribing RNA from their DNA genome while group VI viruses synthesize DNA from RNA using reverse transcriptase before they can reproduce.

44. The diagram below shows the stages during which a virus infects a host cell. During which of the numbered steps does the amount of viral genetic material begin to

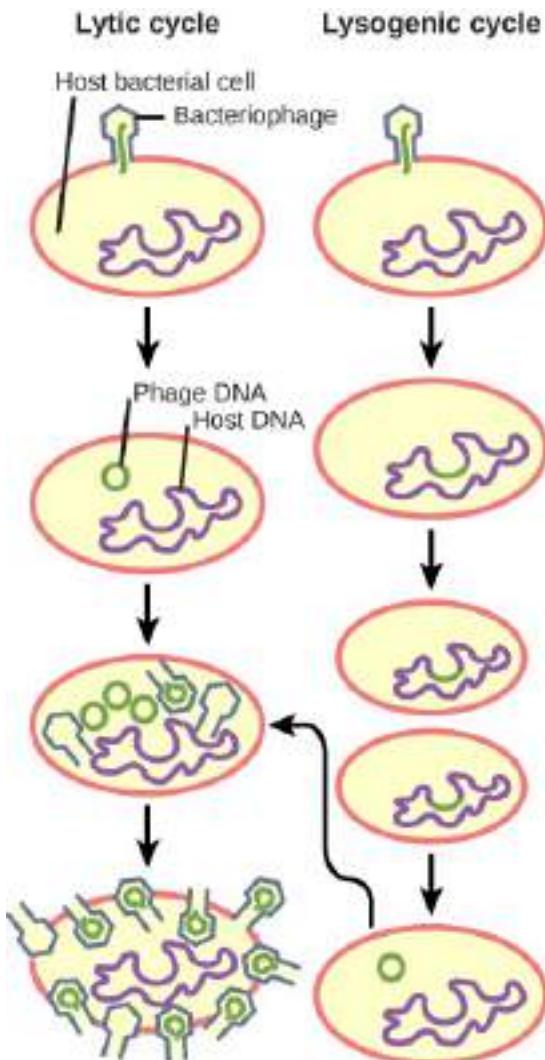

change within the host cell and why?

45. The diagram below shows the stages during which a virus infects a host cell. How could the influenza virus change the function of a host cell? Which has the potential to produce the most copies of the virus?

- a. Because it replicates its DNA within the cell and reproduces, which could interfere with cell processes.
- b. Because it replicates RNA within the cell and reproduces which could interfere with cell processes.
- c. Because it attacks the immune system of the host cell, which would in turn interfere with cell processes.
- d. Because it replicates its protein within the cell and reproduces, which could interfere with cell processes.
- 46.** The diagrams below model the lytic and lysogenic reproductive cycles of viruses. Which cycle would maintain the DNA of the virus over several generations, and why?
- a. Lysogenic, because the viral DNA can be excised from the host cell's DNA when under stress.
- b. Lytic, because the viral DNA can be excised from the host cell's DNA when under stress.
- c. Lytic, because the viral DNA can be passed on when the host cell replicates.
- d. Lysogenic, because the viral DNA can be passed on when the host cell replicates.
- 47.** The diagrams below model the lytic and lysogenic reproductive cycles of viruses. Based on the diagram, identify whether the following statement is true or false, and explain why or why not: "The lysogenic cycle allows viruses to preserve their genome during unfavorable conditions."

- True. Because when the host cell experiences unfavorable conditions, it stops dividing and stays in the same state.
- True. Because the host cell in both the replication stage and during unfavorable conditions stays in the lysogenic cycle as it is more preferable over the lytic cycle.
- False. Because when the host cell experiences unfavorable conditions, the prophage exits the genome and enters the lytic cycle.
- False. Because when the host cell experiences unfavorable conditions, the virus enters latency period.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

48. Influenza A virus is the most pathogenic of the human influenza viruses. Its envelope encloses a protein complex (vRNP) and eight, single-stranded, negative RNA (the complement of a positive RNA strand that can be transcribed by a ribosome) segments (vRNA). Each segment encodes one or two proteins that support viral replication. On the outer surface of the envelope are proteins that recognize and bind to host receptors.

A. Annotate the representation below to briefly **describe** each process associated with a numbered label.

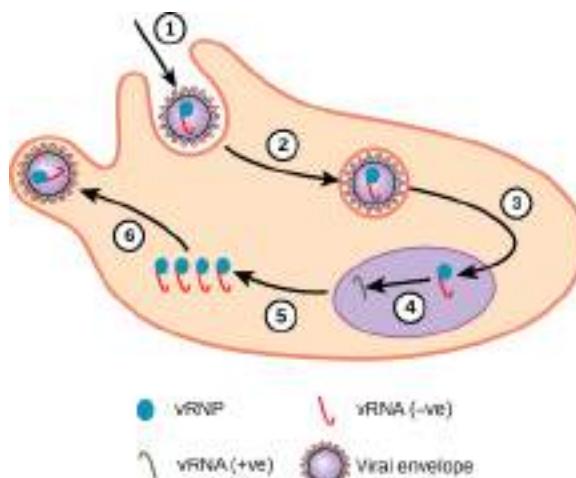

Figure 21.21

B. **Describe** influenza A viral replication as a process regulated by either positive or negative feedback and

**justify** your selection.

The human-acquired immunodeficiency syndrome (AIDS) and many cancers are caused by double-stranded RNA retroviruses.

C. **Contrast** the processes of viral replication of HIV and influenza A virus.

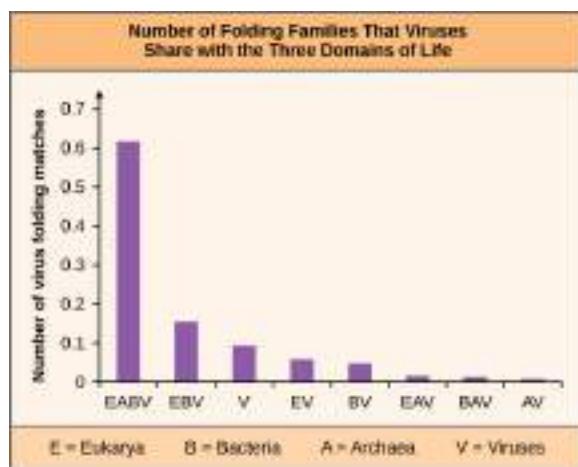

D. **Explain** the difference in the effects of infection by HIV and influenza A virus on host genetic variability.

E. Measured mutation rates for influenza A virus and HIV are nearly identical (Sanjuan et al., *Jour. Virology*, 2010). **Explain** this observation even though host error-checking operates in one of these replication modes.

49. Three-dimensional (3D) structures, or folding, of proteins have been shown to contain more information about evolutionary relationships than the sequences of DNA nucleotides that encode the proteins. Amino acid sequences of rabbit skeletal muscle actin (375 amino acids) and bovine ATPase (386 amino acids) have only 39 locations in common. However, the 3D structure of these proteins are nearly identical (Flaherty et al., *Proc. Natl. Acad. Sci. USA*, 1991). As information about the 3D folding of proteins and the number of sequenced whole genomes has increased, folding has been shown to be an evolutionarily conserved property.

A. **Analyze** these data to **refine** the following model: The evolutionary history of life on Earth can be inferred from variations over time of the nucleotide sequence of a gene.

By applying a classification scheme based on protein folding, Nasir and Caetano-Anollés (*Sci. Adv.* 2015) have determined the number of folding families that viruses share with the three domains. Approximately 60% of the folding patterns found in viruses were common to all three domains, as shown below. Fewer than 10% were unique to viruses.

**Figure 21.22**

Viruses are acellular, and, consequently, they lie outside of the three domains of cellular life. However, their exclusion is increasingly challenged. Since 2012, several very large

viruses have been discovered, each a double-stranded DNA virus with more than one million bases, with some encoding nucleotides and amino acids. However, none encode ribosomes, so these viruses are still dependent on a marine bacteriovore (amoeba or flagellate) host for replication.

Hypotheses regarding the origin of life on Earth need to account for the relationship between proteins and genetic information. Proteins are required to read and write genetic information, but genetic information is required to synthesize proteins. Which of these systems evolved first, and if neither came first, how could they evolve simultaneously? The RNA-first model is based on the idea that ribosomal RNA both encodes and synthesizes proteins.

B. **Describe** a hypothesis for the origin of life on Earth that combines the dual functionality of RNA and the function of retroviral reverse transcriptase to propose a mechanism leading to an ancient, acellular lineage of very large, double-stranded DNA viruses and a first DNA-based cellular life form.

C. Like viruses, the nucleus of a eukaryote uses the machinery of the cell to transcribe DNA and synthesize proteins. **Evaluate** the possibility of the origin of Eukarya by specialization of a very large double-stranded DNA virus.

50. Viruses evolve but leave no fossil evidence that can be used to construct phylogenies. However, viral DNA, especially that of retroviruses, is commonly found in the host genome. By comparing sequences from the same virus integrated at different points in time, the evolutionary history of the virus can be constructed. The viral genomes are typically found incomplete, in segments, and interrupted by stop codons. In jawed vertebrates, retroviral sequences or sequences that have been derived from them are a significant fraction of the whole genome.

A. **Explain** why retroviral DNA rather than the genomes of single-stranded or double-stranded DNA or single-stranded RNA viruses are found in host DNA.

Exaptation occurs when gene expression provides a function that is independent of the selection pressures that have acted on the gene. For example, a pigment that provided selective advantage by reducing damage from solar radiation becomes an element of mating behavior. Feathers that evolved under selection to prevent heat loss become a means of flight.

In a study of viral evolution within host genomes of primates, Katzuorakis and Gifford (*PLOS Genetics*, 2010) found that viral genomes within the host were surprisingly stable; with computer simulation, they estimated the probability of such constancy at 1 in 100,000.

B. **Explain** in terms of selection how viral genetic information that no longer replicates the virus is maintained by the host.

Distemper is an incurable disease of cats, dogs, and their

sister lineages caused by a parvovirus. The virus exploits the host's transferrin, a membrane-bound protein used for iron transport, to attach to the cell. The phylogeny of the *Parvoviridae* family has been constructed (J. Kaebler, *PLOS Pathogens*, 2012). That study revealed the evolution of both the virus and the host protein through selection to resist infection. About 54 million years ago when the lineage of cats (*Feliformia*) diverged from that of dogs (*Caniformia*), the parvovirus envelope diverged as well, conforming to changes in the host's transferrin. In 1978, a worldwide disease in dogs due to a parvovirus suddenly appeared.

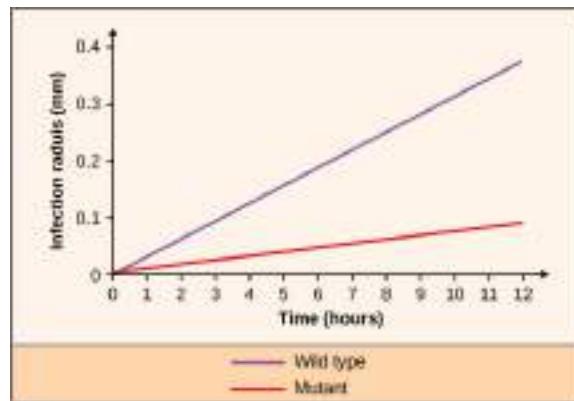

C. **Explain** how this pandemic could have originated in the cat population.

51. A simple calculation of the rate of spread of a pox virus (virion) led researchers at Imperial College London to a new insight. Virions communicate with other virions. The researchers observed that the radius of an approximately circular plaque of infected cells grew to 1.45 mm in just 3 days. They measured the distance between adjacent cells to be 0.037 mm to obtain the apparent time for the lytic cycle (from infection to lysis). They compared this time to the actual rate at which new virions are formed: 5 to 6 hours.

A. **Predict** the radius of infection if the infection process involved a sequence of entry, replication, lysis, and infection of an adjacent cell.

To account for this discrepancy between observed and predicted growth rates, the researchers examined the viral

entry process and discovered that the actin protein on the host cell's surface that provided the viral receptor was modified by attachment. They then found a mutant virus that did not modify the cell surface protein. The dependence of the growth of plaque radius on time for the wild type and mutant are shown in the graph.

**Figure 21.23**

B. **Analyze** these data and compare the infection rates calculated with those predicted in part A.

C. Use the results of this experiment to **support the claim** that responses to information and communication of information affect natural selection.

52. Describe how viral replication introduces genetic variation in the viral population.

# 22 | PROKARYOTES: BACTERIA AND ARCHAEA

**Figure 22.1** Certain prokaryotes can live in extreme environments such as the Morning Glory pool, a hot spring in Yellowstone National Park. The spring's vivid blue color is from the prokaryotes that thrive in its very hot waters. (credit: modification of work by Jon Sullivan)

## Chapter Outline

- 22.1: Prokaryotic Diversity**
- 22.2: Structure of Prokaryotes**
- 22.3: Prokaryotic Metabolism**
- 22.4: Bacterial Diseases in Humans**
- 22.5: Beneficial Prokaryotes**

## Introduction

Most people think of bacteria as disease-causing organisms. Although some bacteria are pathogens, many are not. For example, the commensal bacteria that inhabit our skin and gastrointestinal tract do a host of good things for us. They protect us from pathogens, help us digest our food, and produce some of our vitamins and other nutrients. These activities have been known for a long time. More recently, scientists have gathered evidence that these bacteria may also help regulate our moods, influence our activity levels, and even help control weight by affecting our food choices and absorption patterns. The Human Microbiome Project has begun the process of cataloging our normal bacteria (and archaea) so we can better understand these functions. You can learn more about the Human Microbiome Project [here](http://openstaxcollege.org/l/32microbiome) (<http://openstaxcollege.org/l/32microbiome>) .

## 22.1 | Prokaryotic Diversity

In this section, you will explore the following questions:

- What is the evolutionary history of prokaryotes?
- What are distinguishing features of extremophiles?
- Why is it difficult to culture prokaryotes for study purposes?

### Connection for AP® Courses

In the recent past, scientists grouped living organisms into five kingdoms based on several criteria, including the absence or presence of a nucleus and other membrane-bound organelles, the absence or presence of cell walls, multicellularity, and so on. As we learned earlier, prokaryotes were the first cells to evolve on Earth 3.5 to 4.5 millions of years ago and lacked a nucleus and cytoplasmic organelles. In the late 20<sup>th</sup> century, scientists compared sequences of small-subunit ribosomal RNA, which resulted in a more fundamental way to group organisms on Earth. Based on the differences in the structure of the cell membranes and in rRNA, Carl Woese and his colleagues proposed the three domain system. The domain Bacteria comprises all organisms in the kingdom Eubacteria (bacteria), the domain Archaea comprises the rest of the prokaryotes, and the domain Eukarya comprises all eukaryotes, including protists, fungi, plants, and animals. Prokaryotes exhibit great diversity in form and function and are abundant and ubiquitous. In addition to inhabiting moderate environments like the human digestive system, prokaryotes are found in extreme conditions (**extremophiles**), from boiling hot springs to the Great Salt Lake and to frozen environments in Antarctica.

Because prokaryotes inhabit many different environments, they have evolved multiple strategies for meeting their energy demands, including chemosynthesis, photosynthesis, anaerobic cellular respiration, and aerobic cellular respiration. Hot springs and hydrothermal vents may have been the environments in which life began, and there is fossil evidence of the presence of microbial mats about 3.5 billion years ago. During the first two billion years of Earth's history, the atmosphere lacked sufficient quantities of oxygen, and only anaerobic organisms were able to live. Cyanobacteria evolved from early phototrophs and began the oxygenation of the atmosphere. The increase in oxygen concentration allows the evolution of other life forms with other metabolic processes. Most prokaryotes prefer to live in communities, often forming biofilms.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 2.35][APLO 2.36][APLO 2.37]

Prokaryotes are ubiquitous. They cover every imaginable surface where there is sufficient moisture, and they live on and inside of other living things. In the typical human body, prokaryotic cells outnumber human body cells by about ten to one. They comprise the majority of living things in all ecosystems. Some prokaryotes thrive in environments that are inhospitable for most living things. Prokaryotes recycle **nutrients**—essential substances (such as carbon and nitrogen)—and they drive the evolution of new ecosystems, some of which are natural and others man-made. Prokaryotes have been on Earth since long before multicellular life appeared.

## Prokaryotes, the First Inhabitants of Earth

When and where did life begin? What were the conditions on Earth when life began? Prokaryotes were the first forms of life on Earth, and they existed for billions of years before plants and animals appeared. The Earth and its moon are thought to be about 4.54 billion years old. This estimate is based on evidence from radiometric dating of meteorite material together with other substrate material from Earth and the moon. Early Earth had a very different atmosphere (contained less molecular oxygen) than it does today and was subjected to strong radiation; thus, the first organisms would have flourished where they were more protected, such as in ocean depths or beneath the surface of the Earth. At this time too, strong volcanic activity was common on Earth, so it is likely that these first organisms—the first prokaryotes—were adapted to very high temperatures. Early Earth was prone to geological upheaval and volcanic eruption, and was subject to bombardment by mutagenic radiation from the sun. The first organisms were prokaryotes that could withstand these harsh conditions.

### ***Microbial Mats***

Microbial mats or large biofilms may represent the earliest forms of life on Earth; there is fossil evidence of their presence starting about 3.5 billion years ago. A **microbial mat** is a multi-layered sheet of prokaryotes (**Figure 22.2**) that includes mostly bacteria, but also archaea. Microbial mats are a few centimeters thick, and they typically grow where different types of materials interface, mostly on moist surfaces. The various types of prokaryotes that comprise them carry out different metabolic pathways, and that is the reason for their various colors. Prokaryotes in a microbial mat are held together by a glue-like sticky substance that they secrete called extracellular matrix.

The first microbial mats likely obtained their energy from chemicals found near hydrothermal vents. A **hydrothermal vent** is a breakage or fissure in the Earth's surface that releases geothermally heated water. With the evolution of photosynthesis about 3 billion years ago, some prokaryotes in microbial mats came to use a more widely available energy source—sunlight—whereas others were still dependent on chemicals from hydrothermal vents for energy and food.

**Figure 22.2** This (a) microbial mat, about one meter in diameter, grows over a hydrothermal vent in the Pacific Ocean in a region known as the “Pacific Ring of Fire.” The mat helps retain microbial nutrients. Chimneys such as the one indicated by the arrow allow gases to escape. (b) In this micrograph, bacteria are visualized using fluorescence microscopy. (credit a: modification of work by Dr. Bob Embley, NOAA PMEL, Chief Scientist; credit b: modification of work by Ricardo Murga, Rodney Donlan, CDC; scale-bar data from Matt Russell)

### Stromatolites

Fossilized microbial mats represent the earliest record of life on Earth. A **stromatolite** is a sedimentary structure formed when minerals are precipitated out of water by prokaryotes in a microbial mat (Figure 22.3). Stromatolites form layered rocks made of carbonate or silicate. Although most stromatolites are artifacts from the past, there are places on Earth where stromatolites are still forming. For example, growing stromatolites have been found in the Anza-Borrego Desert State Park in San Diego County, California.

**Figure 22.3** (a) These living stromatolites are located in Shark Bay, Australia. (b) These fossilized stromatolites, found in Glacier National Park, Montana, are nearly 1.5 billion years old. (credit a: Robert Young; credit b: P. Carrara, NPS)

### The Ancient Atmosphere

Evidence indicates that during the first two billion years of Earth’s existence, the atmosphere was **anoxic**, meaning that there was no molecular oxygen. Therefore, only those organisms that can grow without oxygen—**anaerobic** organisms—were able to live. Autotrophic organisms that convert solar energy into chemical energy are called **phototrophs**, and they appeared within one billion years of the formation of Earth. Then, **cyanobacteria**, also known as blue-green algae, evolved from these simple phototrophs one billion years later. Cyanobacteria (Figure 22.4) began the oxygenation of the atmosphere. Increased atmospheric oxygen allowed the development of more efficient O<sub>2</sub>-utilizing catabolic pathways. It also opened up the land to increased colonization, because some O<sub>2</sub> is converted into O<sub>3</sub> (ozone) and ozone effectively absorbs the ultraviolet light that would otherwise cause lethal mutations in DNA. Ultimately, the increase in O<sub>2</sub> concentrations allowed the evolution of other life forms.

**Figure 22.4** This hot spring in Yellowstone National Park flows toward the foreground. Cyanobacteria in the spring are green, and as water flows down the gradient, the intensity of the color increases as cell density increases. The water is cooler at the edges of the stream than in the center, causing the edges to appear greener. (credit: Graciela Brellés-Mariño)

## science practices CONNECTION for AP<sup>®</sup> Courses

Early Earth was inhospitable to most life as we know it today, with a substantial amount of geological upheaval, volcanic activity, and an anoxic atmosphere (which means it lacked oxygen). Therefore, the origin of life on Earth is of great interest to scientists.

One of the earliest hypotheses of how life originated on Earth was by panspermia, which dates back to the 5<sup>th</sup> century BC. Panspermia is the idea that life is distributed to different parts of the universe on objects such as meteoroids and asteroids. If this were to occur, organic compounds and microorganisms would be able to survive the extreme conditions of space.

However, in the 1960s, scientists Stanley Miller and Harold Urey conducted laboratory experiments that showed it was possible for organic compounds, including amino acids, to be formed under certain conditions from inorganic molecules and energy, both of which would have been present in the early conditions of Earth. Subsequently, fossilized evidence of microbial mats by deep sea hydrothermal vents that dates back 3.5 billion years was discovered. Consequently, there are now several hypotheses regarding how life could have evolved on Earth.

### Activity

Perform internet research using reliable webpages containing current scientific evidence supporting the ideas that 1) life originated on Earth, and 2) that life arrived on Earth from an extraterrestrial object, such as an asteroid or comet. Then decide which idea has more supporting evidence. Be able to justify your conclusion.

### Think About It

If organic compounds, which eventually formed organisms, could have formed both extraterrestrially and on Earth, why would it be less complicated, and thus more likely, that life formed on Earth?

### Think About It

Even though Miller and Urey showed that organic molecules could be produced from conditions of early Earth, why are there still different hypotheses about how life could have originated on Earth?

## Microbes Are Adaptable: Life in Moderate and Extreme Environments

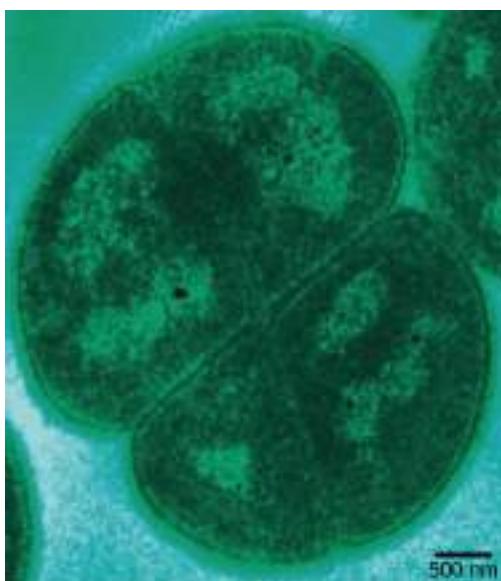

Some organisms have developed strategies that allow them to survive harsh conditions. Prokaryotes thrive in a vast array of environments: Some grow in conditions that would seem very normal to us, whereas others are able to thrive and grow under conditions that would kill a plant or animal. Almost all prokaryotes have a cell wall, a protective structure that allows them to survive in both hyper- and hypo-osmotic conditions. Some soil bacteria are able to form endospores that resist heat and drought, thereby allowing the organism to survive until favorable conditions recur. These adaptations, along with others, allow bacteria to be the most abundant life form in all terrestrial and aquatic ecosystems.

Other bacteria and archaea are adapted to grow under extreme conditions and are called **extremophiles**, meaning “lovers of extremes.” Extremophiles have been found in all kinds of environments: the depth of the oceans, hot springs, the Arctic and the Antarctic, in very dry places, deep inside Earth, in harsh chemical environments, and in high radiation environments ([Figure 22.5](#)), just to mention a few. These organisms give us a better understanding of prokaryotic diversity and open up the possibility of finding new prokaryotic species that may lead to the discovery of new therapeutic drugs or have industrial applications. Because they have specialized adaptations that allow them to live in extreme conditions, many extremophiles cannot survive in moderate environments. There are many different groups of extremophiles: They are identified based on the conditions in which they grow best, and several habitats are extreme in multiple ways. For example, a soda lake is both salty and alkaline, so organisms that live in a soda lake must be both alkaliphiles and halophiles ([Table 22.1](#)). Other extremophiles, like **radioresistant** organisms, do not prefer an extreme environment (in this case, one with high levels of radiation), but have adapted to survive in it ([Figure 22.5](#)).

### Extremophiles and Their Preferred Conditions

| Extremophile Type | Conditions for Optimal Growth               |
|-------------------|---------------------------------------------|
| Acidophiles       | pH 3 or below                               |
| Alkaliphiles      | pH 9 or above                               |
| Thermophiles      | Temperature 60–80 °C (140–176 °F)           |
| Hyperthermophiles | Temperature 80–122 °C (176–250 °F)          |
| Psychrophiles     | Temperature of -15-10 °C (5-50 °F) or lower |
| Halophiles        | Salt concentration of at least 0.2 M        |
| Osmophiles        | High sugar concentration                    |

**Table 22.1**

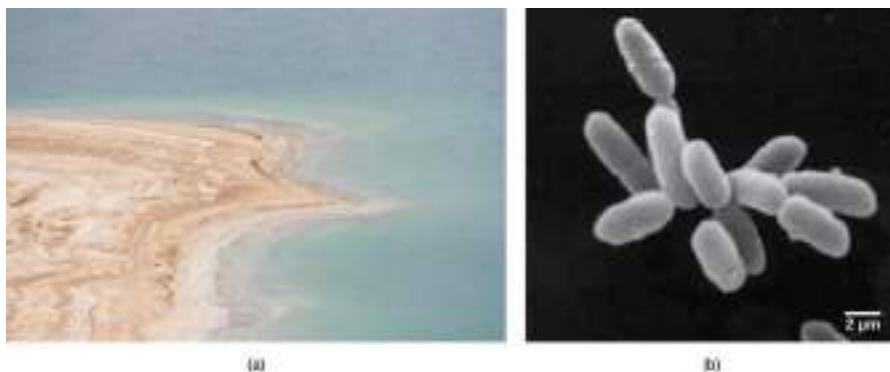

**Figure 22.5** *Deinococcus radiodurans*, visualized in this false color transmission electron micrograph, is a prokaryote that can tolerate very high doses of ionizing radiation. It has developed DNA repair mechanisms that allow it to reconstruct its chromosome even if it has been broken into hundreds of pieces by radiation or heat. (credit: modification of work by Michael Daly; scale-bar data from Matt Russell)

### Prokaryotes in the Dead Sea

One example of a very harsh environment is the Dead Sea, a hypersaline basin that is located between Jordan and Israel. Hypersaline environments are essentially concentrated seawater. In the Dead Sea, the sodium concentration is 10 times higher than that of seawater, and the water contains high levels of magnesium (about 40 times higher than in seawater) that would be toxic to most living things. Iron, calcium, and magnesium, elements that form divalent ions ( $\text{Fe}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{Mg}^{2+}$ ), produce what is commonly referred to as “hard” water. Taken together, the high concentration of divalent cations<sup>[1]</sup>, the acidic pH (6.0), and the intense solar radiation flux make the Dead Sea a unique, and uniquely hostile, ecosystem (Figure 22.6).

What sort of prokaryotes do we find in the Dead Sea? The extremely salt-tolerant bacterial mats include *Halobacterium*, *Haloferax volcanii* (which is found in other locations, not only the Dead Sea), *Halorubrum sodomense*, and *Halobaculum gomorrense*, and the archaea *Haloarcula marismortui*, among others.

**Figure 22.6** (a) The Dead Sea is hypersaline. Nevertheless, salt-tolerant bacteria thrive in this sea. (b) These halobacteria cells can form salt-tolerant bacterial mats. (credit a: Julien Menichini; credit b: NASA; scale-bar data from Matt Russell)

### Unculturable Prokaryotes and the Viable-but-Non-Culturable State

Microbiologists typically grow prokaryotes in the laboratory using an appropriate culture medium containing all the nutrients needed by the target organism. The medium can be liquid, broth, or solid. After an incubation time at the right temperature, there should be evidence of microbial growth (Figure 22.7). The process of culturing bacteria is complex

1. Bodaker, I., Itai, S., Suzuki, M.T., Feingersch, R., Rosenberg, M., Maguire, M.E., Shimshon, B., and others. Comparative community genomics in the Dead Sea: An increasingly extreme environment. *The ISME Journal* 4 (2010): 399–407, doi:10.1038/ismej.2009.141. published online 24 December 2009.

and is one of the greatest discoveries of modern science. German physician Robert Koch is credited with discovering the techniques for pure culture, including staining and using growth media. His assistant Julius Petri invented the Petri dish whose use persists in today's laboratories. Koch worked primarily with the *Mycobacterium tuberculosis* bacterium that causes tuberculosis and developed postulates to identify disease-causing organisms that continue to be widely used in the medical community. Koch's postulates include that an organism can be identified as the cause of disease when it is present in all infected samples and absent in all healthy samples, and it is able to reproduce the infection after being cultured multiple times. Today, cultures remain a primary diagnostic tool in medicine and other areas of molecular biology.

**Figure 22.7** In these agar plates, the growth medium is supplemented with red blood cells. Blood agar becomes transparent in the presence of hemolytic *Streptococcus*, which destroys red blood cells and is used to diagnose *Streptococcus* infections. The plate on the left is inoculated with non-hemolytic *Staphylococcus* (large white colonies), and the plate on the right is inoculated with hemolytic *Streptococcus* (tiny clear colonies). If you look closely at the right plate, you can see that the agar surrounding the bacteria has turned clear. (credit: Bill Branson, NCI)

Some prokaryotes, however, cannot grow in a laboratory setting. In fact, over 99 percent of bacteria and archaea are unculturable. For the most part, this is due to a lack of knowledge as to what to feed these organisms and how to grow them; they have special requirements for growth that remain unknown to scientists, such as needing specific micronutrients, pH, temperature, pressure, co-factors, or co-metabolites. Some bacteria cannot be cultured because they are obligate intracellular parasites and cannot be grown outside a host cell.

In other cases, culturable organisms become unculturable under stressful conditions, even though the same organism could be cultured previously. Those organisms that cannot be cultured but are not dead are in a **viable-but-non-culturable** (VBNC) state. The VBNC state occurs when prokaryotes respond to environmental stressors by entering a dormant state that allows their survival. The criteria for entering into the VBNC state are not completely understood. In a process called **resuscitation**, the prokaryote can go back to "normal" life when environmental conditions improve.

Is the VBNC state an unusual way of living for prokaryotes? In fact, most of the prokaryotes living in the soil or in oceanic waters are non-culturable. It has been said that only a small fraction, perhaps one percent, of prokaryotes can be cultured under laboratory conditions. If these organisms are non-culturable, then how is it known whether they are present and alive? Microbiologists use molecular techniques, such as the polymerase chain reaction (PCR), to amplify selected portions of DNA of prokaryotes, demonstrating their existence. Recall that PCR can make billions of copies of a DNA segment in a process called amplification.

## The Ecology of Biofilms

Until a couple of decades ago, microbiologists used to think of prokaryotes as isolated entities living apart. This model, however, does not reflect the true ecology of prokaryotes, most of which prefer to live in communities where they can interact. A **biofilm** is a microbial community (**Figure 22.8**) held together in a gummy-textured matrix that consists primarily of polysaccharides secreted by the organisms, together with some proteins and nucleic acids. Biofilms grow attached to surfaces. Some of the best-studied biofilms are composed of prokaryotes, although fungal biofilms have also been described as well as some composed of a mixture of fungi and bacteria.

Biofilms are present almost everywhere: they can cause the clogging of pipes and readily colonize surfaces in industrial settings. In recent, large-scale outbreaks of bacterial contamination of food, biofilms have played a major role. They also colonize household surfaces, such as kitchen counters, cutting boards, sinks, and toilets, as well as places on the human body, such as the surfaces of our teeth.

Interactions among the organisms that populate a biofilm, together with their protective exopolysaccharidic (EPS) environment, make these communities more robust than free-living, or planktonic, prokaryotes. The sticky substance that holds bacteria together also excludes most antibiotics and disinfectants, making biofilm bacteria harder than their

planktonic counterparts. Overall, biofilms are very difficult to destroy because they are resistant to many common forms of sterilization.

**visual CONNECTION**

**Figure 22.8** Five stages of biofilm development are shown. During stage 1, initial attachment, bacteria adhere to a solid surface via weak van der Waals interactions. During stage 2, irreversible attachment, hairlike appendages called pili permanently anchor the bacteria to the surface. During stage 3, maturation I, the biofilm grows through cell division and recruitment of other bacteria. An extracellular matrix composed primarily of polysaccharides holds the biofilm together. During stage 4, maturation II, the biofilm continues to grow and takes on a more complex shape. During stage 5, dispersal, the biofilm matrix is partly broken down, allowing some bacteria to escape and colonize another surface. Micrographs of a *Pseudomonas aeruginosa* biofilm in each of the stages of development are shown. (credit: D. Davis, Don Monroe, PLoS)

## 22.2 | Structure of Prokaryotes

In this section, you will explore the following questions:

- What are similarities in the structures of the prokaryotes, Archaea and Bacteria?
- What are examples of structural differences between Archaea and Bacteria?

### Connection for AP<sup>®</sup> Courses

Domains Archaea and Bacteria contain single-celled organisms lacking a nucleus and other membrane-bound organelles. The two groups have substantial biochemical and structural differences. Most have a cell wall external to the plasma cell membrane, the composition of which can vary among groups, and many have additional structures such as flagella and pili. Prokaryotes also have ribosomes, where protein synthesis occurs. For the purpose of AP<sup>®</sup>, you do not have to memorize the various groups of bacteria. You should, however, be able to distinguish between prokaryotes and eukaryotes and know the domains.

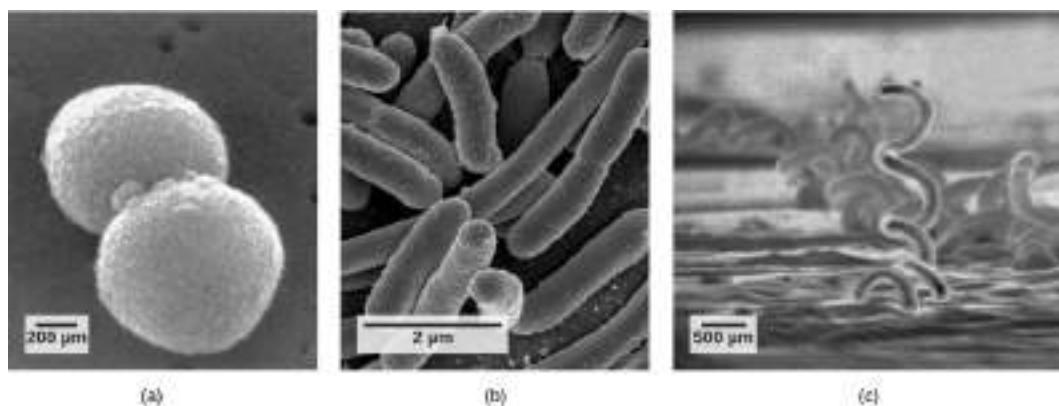

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 and Big Idea 3 of the AP<sup>®</sup> Biology Curriculum Framework. The AP<sup>®</sup> Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP<sup>®</sup> Biology course, an inquiry-based laboratory experience, instructional activities, and AP<sup>®</sup> exam questions. A learning objective merges required content with one or more of the seven science practices.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 2.5][APLO 2.13][APLO 2.14][APLO 4.9]

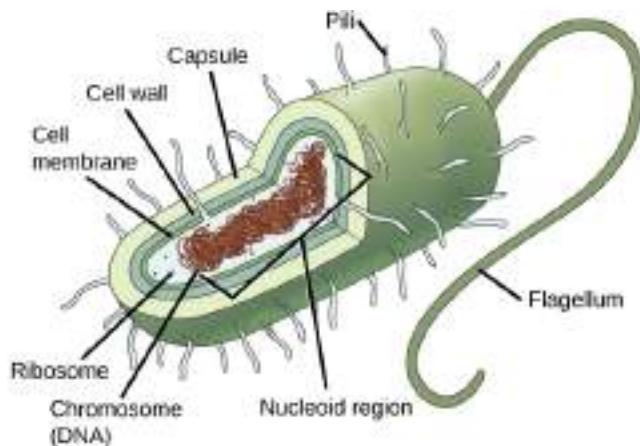

There are many differences between prokaryotic and eukaryotic cells. However, all cells have four common structures: the plasma membrane, which functions as a barrier for the cell and separates the cell from its environment; the cytoplasm, a jelly-like substance inside the cell; nucleic acids, the genetic material of the cell; and ribosomes, where protein synthesis takes place. Prokaryotes come in various shapes, but many fall into three categories: cocci (spherical), bacilli (rod-shaped), and spirilli (spiral-shaped) ([Figure 22.9](#)).

**Figure 22.9** Prokaryotes fall into three basic categories based on their shape, visualized here using scanning electron microscopy: (a) cocci, or spherical (a pair is shown); (b) bacilli, or rod-shaped; and (c) spirilli, or spiral-shaped. (credit a: modification of work by Janice Haney Carr, Dr. Richard Facklam, CDC; credit c: modification of work by Dr. David Cox; scale-bar data from Matt Russell)

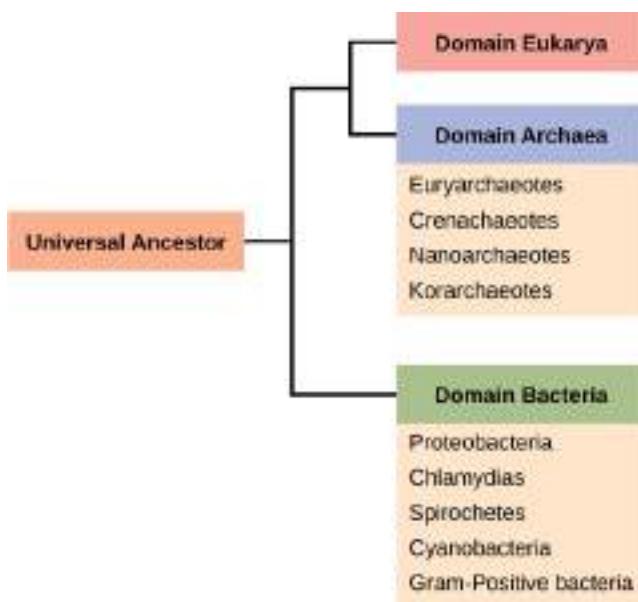

## The Prokaryotic Cell

Recall that prokaryotes (Figure 22.10) are unicellular organisms that lack organelles or other internal membrane-bound structures. Therefore, they do not have a nucleus but instead generally have a single chromosome—a piece of circular, double-stranded DNA located in an area of the cell called the nucleoid. Most prokaryotes have a cell wall outside the plasma membrane.

**Figure 22.10** The features of a typical prokaryotic cell are shown.

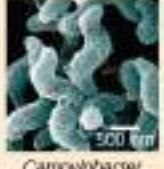

Recall that prokaryotes are divided into two different domains, Bacteria and Archaea, which together with Eukarya, comprise the three domains of life (Figure 22.11).

**Figure 22.11** Bacteria and Archaea are both prokaryotes but differ enough to be placed in separate domains. An ancestor of modern Archaea is believed to have given rise to Eukarya, the third domain of life. Archaeal and bacterial phyla are shown; the evolutionary relationship between these phyla is still open to debate.

The composition of the cell wall differs significantly between the domains Bacteria and Archaea. The composition of their cell walls also differs from the eukaryotic cell walls found in plants (cellulose) or fungi and insects (chitin). The cell wall functions as a protective layer, and it is responsible for the organism's shape. Some bacteria have an outer **capsule** outside the cell wall. Other structures are present in some prokaryotic species, but not in others (Table 22.2). For example, the capsule found in some species enables the organism to attach to surfaces, protects it from dehydration and attack by phagocytic cells, and makes pathogens more resistant to our immune responses. Some species also have flagella (singular, flagellum) used for locomotion, and **pili** (singular, pilus) used for attachment to surfaces. Plasmids, which consist of extra-chromosomal DNA, are also present in many species of bacteria and archaea.

Characteristics of phyla of Bacteria are described in [Figure 22.12](#) and [Figure 22.13](#); Archaea are described in [Figure 22.14](#).

| Bacteria of Phylum Proteobacteria                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                      |

Stetter; credit “korarchaeota”: modification of work by Office of Science of the U.S. Dept. of Energy; scale-bar data from Matt Russell)

### The Plasma Membrane

The plasma membrane is a thin lipid bilayer (6 to 8 nanometers) that completely surrounds the cell and separates the inside from the outside. Its selectively permeable nature keeps ions, proteins, and other molecules within the cell and prevents them from diffusing into the extracellular environment, while other molecules may move through the membrane. Recall that the general structure of a cell membrane is a phospholipid bilayer composed of two layers of lipid molecules. In archaeal cell membranes, isoprene (phytanyl) chains linked to glycerol replace the fatty acids linked to glycerol in bacterial membranes. Some archaeal membranes are lipid monolayers instead of bilayers (Figure 22.14).

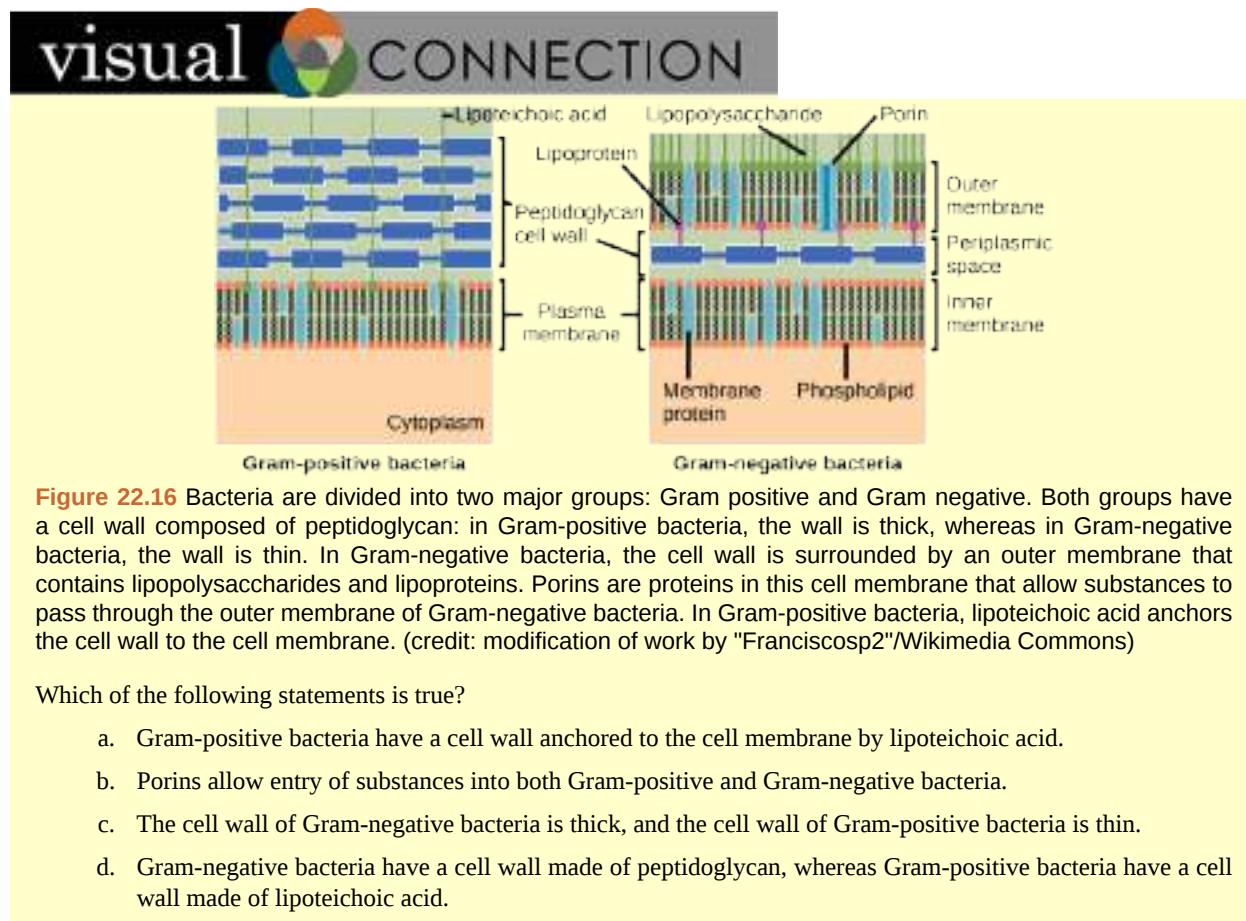

**Figure 22.15** Archaeal phospholipids differ from those found in Bacteria and Eukarya in two ways. First, they have branched phytanyl sidechains instead of linear ones. Second, an ether bond instead of an ester bond connects the lipid to the glycerol.

### The Cell Wall

The cytoplasm of prokaryotic cells has a high concentration of dissolved solutes. Therefore, the osmotic pressure within the cell is relatively high. The cell wall is a protective layer that surrounds some cells and gives them shape and rigidity. It is located outside the cell membrane and prevents osmotic lysis (bursting due to increasing volume). The chemical composition of the cell walls varies between archaea and bacteria, and also varies between bacterial species.

Bacterial cell walls contain **peptidoglycan**, composed of polysaccharide chains that are cross-linked by unusual peptides containing both L- and D-amino acids including D-glutamic acid and D-alanine. Proteins normally have only L-amino acids; as a consequence, many of our antibiotics work by mimicking D-amino acids and therefore have specific effects on bacterial cell wall development. There are more than 100 different forms of peptidoglycan. **S-layer** (surface layer) proteins are also present on the outside of cell walls of both archaea and bacteria.

Bacteria are divided into two major groups: **Gram positive** and **Gram negative**, based on their reaction to Gram staining. Note that all Gram-positive bacteria belong to one phylum; bacteria in the other phyla (Proteobacteria, Chlamydiae, Spirochetes, Cyanobacteria, and others) are Gram-negative. The Gram staining method is named after its inventor, Danish scientist Hans Christian Gram (1853–1938). The different bacterial responses to the staining procedure are ultimately due to cell wall structure. Gram-positive organisms typically lack the outer membrane found in Gram-negative organisms (Figure 22.15). Up to 90 percent of the cell wall in Gram-positive bacteria is composed of peptidoglycan, and most of the rest is composed of acidic substances called **teichoic acids**. Teichoic acids may be covalently linked to lipids in the plasma membrane to form lipoteichoic acids. Lipoteichoic acids anchor the cell wall to the cell membrane. Gram-negative bacteria have a relatively thin cell wall composed of a few layers of peptidoglycan (only 10 percent of the total cell wall), surrounded by an outer envelope containing lipopolysaccharides (LPS) and lipoproteins. This outer envelope is sometimes referred to as a second lipid bilayer. The chemistry of this outer envelope is very different, however, from that of the typical lipid bilayer that forms plasma membranes.

**Figure 22.16** Bacteria are divided into two major groups: Gram positive and Gram negative. Both groups have a cell wall composed of peptidoglycan: in Gram-positive bacteria, the wall is thick, whereas in Gram-negative bacteria, the wall is thin. In Gram-negative bacteria, the cell wall is surrounded by an outer membrane that contains lipopolysaccharides and lipoproteins. Porins are proteins in this cell membrane that allow substances to pass through the outer membrane of Gram-negative bacteria. In Gram-positive bacteria, lipoteichoic acid anchors the cell wall to the cell membrane. (credit: modification of work by "Franciscosp2"/Wikimedia Commons)

Which of the following statements is true?

- Gram-positive bacteria have a cell wall anchored to the cell membrane by lipoteichoic acid.
- Porins allow entry of substances into both Gram-positive and Gram-negative bacteria.
- The cell wall of Gram-negative bacteria is thick, and the cell wall of Gram-positive bacteria is thin.
- Gram-negative bacteria have a cell wall made of peptidoglycan, whereas Gram-positive bacteria have a cell wall made of lipoteichoic acid.

Archaeal cell walls do not have peptidoglycan. There are four different types of Archaeal cell walls. One type is composed of **pseudopeptidoglycan**, which is similar to peptidoglycan in morphology but contains different sugars in the polysaccharide chain. The other three types of cell walls are composed of polysaccharides, glycoproteins, or pure protein.

### Structural Differences and Similarities between Bacteria and Archaea

| Structural Characteristic | Bacteria               | Archaea                          |
|---------------------------|------------------------|----------------------------------|
| Cell type                 | Prokaryotic            | Prokaryotic                      |
| Cell morphology           | Variable               | Variable                         |
| Cell wall                 | Contains peptidoglycan | Does not contain peptidoglycan   |
| Cell membrane type        | Lipid bilayer          | Lipid bilayer or lipid monolayer |
| Plasma membrane lipids    | Fatty acids            | Phytanyl groups                  |

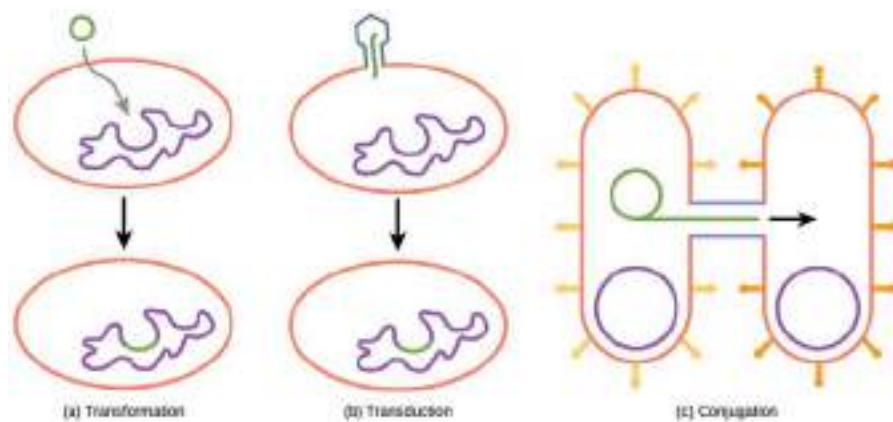

**Table 22.2**

### Reproduction

Reproduction in prokaryotes is asexual and usually takes place by binary fission. Recall that the DNA of a prokaryote exists as a single, circular chromosome. Prokaryotes do not undergo mitosis. Rather the chromosome is replicated and the two resulting copies separate from one another, due to the growth of the cell. The prokaryote, now enlarged, is pinched inward at its equator and the two resulting cells, which are clones, separate. Binary fission does not provide an opportunity for genetic recombination or genetic diversity, but prokaryotes can share genes by three other mechanisms.

In **transformation**, the prokaryote takes in DNA found in its environment that is shed by other prokaryotes. If a nonpathogenic bacterium takes up DNA for a toxin gene from a pathogen and incorporates the new DNA into its own chromosome, it too may become pathogenic. In **transduction**, bacteriophages, the viruses that infect bacteria, sometimes also move short pieces of chromosomal DNA from one bacterium to another. Transduction results in a recombinant organism. Archaea are not affected by bacteriophages but instead have their own viruses that translocate genetic material from one individual to another. In **conjugation**, DNA is transferred from one prokaryote to another by means of a pilus, which brings the organisms into contact with one another. The DNA transferred can be in the form of a plasmid or as a hybrid, containing both plasmid and chromosomal DNA. These three processes of DNA exchange are shown in **Figure 22.17**.

Reproduction can be very rapid: a few minutes for some species. This short generation time coupled with mechanisms of genetic recombination and high rates of mutation result in the rapid evolution of prokaryotes, allowing them to respond to environmental changes (such as the introduction of an antibiotic) very quickly.

**Figure 22.17** Besides binary fission, there are three other mechanisms by which prokaryotes can exchange DNA. In (a) transformation, the cell takes up prokaryotic DNA directly from the environment. The DNA may remain separate as plasmid DNA or be incorporated into the host genome. In (b) transduction, a bacteriophage injects DNA into the cell that contains a small fragment of DNA from a different prokaryote. In (c) conjugation, DNA is transferred from one cell to another via a mating bridge that connects the two cells after the sex pilus draws the two bacteria close enough to form the bridge.

# evolution CONNECTION

## The Evolution of Prokaryotes

How do scientists answer questions about the evolution of prokaryotes? Unlike with animals, artifacts in the fossil record of prokaryotes offer very little information. Fossils of ancient prokaryotes look like tiny bubbles in rock. Some scientists turn to genetics and to the principle of the molecular clock, which holds that the more recently two species have diverged, the more similar their genes (and thus proteins) will be. Conversely, species that diverged long ago will have more genes that are dissimilar.

Scientists at the NASA Astrobiology Institute and at the European Molecular Biology Laboratory collaborated<sup>[2]</sup> to analyze the molecular evolution of 32 specific proteins common to 72 species of prokaryotes. The model they derived from their data indicates that three important groups of bacteria—Actinobacteria, *Deinococcus*, and Cyanobacteria (which the authors call *Terrabacteria*)—were the first to colonize land. (Recall that *Deinococcus* is a genus of prokaryote—a bacterium—that is highly resistant to ionizing radiation.) Cyanobacteria are photosynthesizers, while Actinobacteria are a group of very common bacteria that include species important in decomposition of organic wastes.

The timelines of divergence suggest that bacteria (members of the domain Bacteria) diverged from common ancestral species between 2.5 and 3.2 billion years ago, whereas archaea diverged earlier: between 3.1 and 4.1 billion years ago. Eukarya later diverged off the Archaean line. Stromatolites are some of the oldest fossilized organisms on Earth at around 3.5 million years ago. There is evidence that these prokaryotes were also some of the first photosynthesizers on Earth. In fact, bacterial prokaryotes were likely responsible for the first accumulation of oxygen in our atmosphere through photosynthesis. The group *Terrabacteria* possessed many adaptations for living on land, such as resistance to drying. Some of these adaptations were also related to photosynthesis, such as compounds that protect cells from excess light. These early prokaryotic pathways related to photosynthesis were the foundation for photosynthesis in eukaryotic cells. This is evidenced by the similarity in structure and function between some photosynthetic prokaryotes and eukaryotic chloroplasts.

## Think About It

What features and metabolic processes do all cells, both prokaryotes and eukaryotes, have in common? How do prokaryotes and eukaryotes differ?

## 22.3 | Prokaryotic Metabolism

In this section, you will explore the following questions:

- What are examples of macronutrients needs by prokaryotes, and what is their importance?
- How do prokaryotes obtain free energy and carbon for life processes?
- What are the roles of prokaryotes in the carbon and nitrogen cycles?

## Connection for AP® Courses

Because prokaryotes are metabolically diverse organisms, they can flourish in many different environments using a wide

2. Battistuzzi, FU, Feijao, A, and Hedges, SB. A genomic timescale of prokaryote evolution: Insights into the origin of methanogenesis, phototrophy, and the colonization of land. *BioMed Central: Evolutionary Biology* 4 (2004): 44, doi:10.1186/1471-2148-4-44.

range of energy and carbon sources. Some are decomposers that are essential to the cycling of nutrients in ecosystems, for example, carbon and nitrogen cycles. (Later, we will explore in more depth the role of these cycles in ecosystems.) Many bacteria form symbiotic relationships with other organisms; for example, nitrogen-fixing bacteria live on the roots of legumes. Other bacteria are disease-causing pathogens or parasites.

Like all cells, prokaryotes require macronutrients (including carbon, hydrogen, nitrogen, oxygen, phosphorus, and sulfur) and micronutrients, such as metallic elements from growth and enzyme function.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

 [APLO 4.7][APLO 4.10][APLO 4.23][APLO 2.28]

## Needs of Prokaryotes

The diverse environments and ecosystems on Earth have a wide range of conditions in terms of temperature, available nutrients, acidity, salinity, and energy sources. Prokaryotes are very well equipped to make their living out of a vast array of nutrients and conditions. To live, prokaryotes need a source of energy, a source of carbon, and some additional nutrients.

### Macronutrients

Cells are essentially a well-organized assemblage of macromolecules and water. Recall that macromolecules are produced by the polymerization of smaller units called monomers. For cells to build all of the molecules required to sustain life, they need certain substances, collectively called **nutrients**. When prokaryotes grow in nature, they obtain their nutrients from the environment. Nutrients that are required in large amounts are called macronutrients, whereas those required in smaller or trace amounts are called micronutrients. Just a handful of elements are considered macronutrients—carbon, hydrogen,

oxygen, nitrogen, phosphorus, and sulfur. (A mnemonic for remembering these elements is the acronym *CHONPS*.)

Why are these macronutrients needed in large amounts? They are the components of organic compounds in cells, including water. Carbon is the major element in all macromolecules: carbohydrates, proteins, nucleic acids, lipids, and many other compounds. Carbon accounts for about 50 percent of the composition of the cell. Nitrogen represents 12 percent of the total dry weight of a typical cell and is a component of proteins, nucleic acids, and other cell constituents. Most of the nitrogen available in nature is either atmospheric nitrogen ( $N_2$ ) or another inorganic form. Diatomic ( $N_2$ ) nitrogen, however, can be converted into an organic form only by certain organisms, called nitrogen-fixing organisms. Both hydrogen and oxygen are part of many organic compounds and of water. Phosphorus is required by all organisms for the synthesis of nucleotides and phospholipids. Sulfur is part of the structure of some amino acids such as cysteine and methionine, and is also present in several vitamins and coenzymes. Other important macronutrients are potassium (K), magnesium (Mg), calcium (Ca), and sodium (Na). Although these elements are required in smaller amounts, they are very important for the structure and function of the prokaryotic cell.

### **Micronutrients**

In addition to these macronutrients, prokaryotes require various metallic elements in small amounts. These are referred to as micronutrients or trace elements. For example, iron is necessary for the function of the cytochromes involved in electron-transport reactions. Some prokaryotes require other elements—such as boron (B), chromium (Cr), and manganese (Mn)—primarily as enzyme cofactors.

### **The Ways in Which Prokaryotes Obtain Energy**

Prokaryotes can use different sources of energy to assemble macromolecules from smaller molecules. **Phototrophs** (or phototrophic organisms) obtain their energy from sunlight. **Chemotrophs** (or chemosynthetic organisms) obtain their energy from chemical compounds. Chemotrophs that can use organic compounds as energy sources are called chemoorganotrophs. Those that can also use inorganic compounds as energy sources are called chemolithotrophs.

### **The Ways in Which Prokaryotes Obtain Carbon**

Prokaryotes not only can use different sources of energy but also different sources of carbon compounds. Recall that organisms that are able to fix inorganic carbon are called autotrophs. Autotrophic prokaryotes synthesize organic molecules from carbon dioxide. In contrast, heterotrophic prokaryotes obtain carbon from organic compounds. To make the picture more complex, the terms that describe how prokaryotes obtain energy and carbon can be combined. Thus, photoautotrophs use energy from sunlight, and carbon from carbon dioxide and water, whereas chemoheterotrophs obtain energy and carbon from an organic chemical source. Chemolitoautotrophs obtain their energy from inorganic compounds, and they build their complex molecules from carbon dioxide. The table below (Table 22.3) summarizes carbon and energy sources in prokaryotes.

### **Carbon and Energy Sources in Prokaryotes**

| Energy Sources |                    | Carbon Sources      |                   |
|----------------|--------------------|---------------------|-------------------|
| Light          | Chemicals          | Carbon dioxide      | Organic compounds |
| Phototrophs    | Chemotrophs        | Autotrophs          | Heterotrophs      |
|                | Organic chemicals  | Inorganic chemicals |                   |
|                | Chemo-organotrophs | Chemolithotrophs    |                   |

**Table 22.3**

### **Role of Prokaryotes in Ecosystems**

Prokaryotes are ubiquitous: There is no niche or ecosystem in which they are not present. Prokaryotes play many roles in the environments they occupy. The roles they play in the carbon and nitrogen cycles are vital to life on Earth.

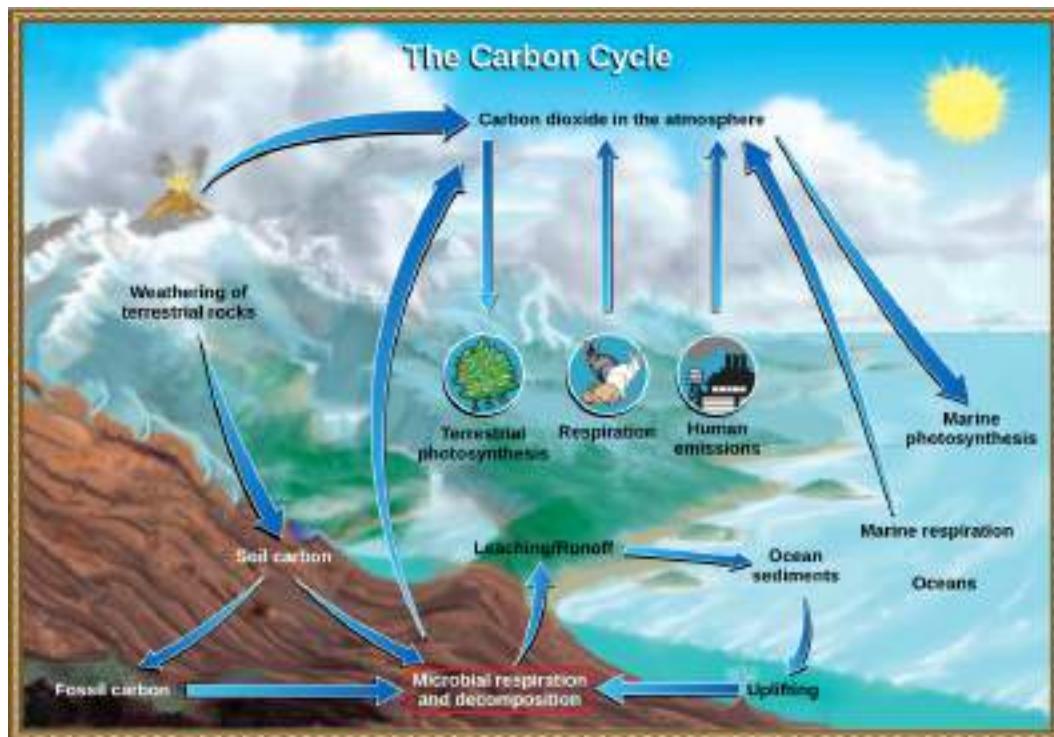

#### **Prokaryotes and the Carbon Cycle**

Carbon is one of the most important macronutrients, and prokaryotes play an important role in the carbon cycle (Figure 22.18). Carbon is cycled through Earth's major reservoirs: land, the atmosphere, aquatic environments, sediments and rocks, and biomass. The movement of carbon is via carbon dioxide, which is removed from the atmosphere by land plants and marine prokaryotes, and is returned to the atmosphere via the respiration of chemoorganotrophic organisms, including prokaryotes, fungi, and animals. Although the largest carbon reservoir in terrestrial ecosystems is in rocks and sediments,

that carbon is not readily available.

A large amount of available carbon is found in land plants. Plants, which are producers, use carbon dioxide from the air to synthesize carbon compounds. Related to this, one very significant source of carbon compounds is humus, which is a mixture of organic materials from dead plants and prokaryotes that have resisted decomposition. Consumers such as animals use organic compounds generated by producers and release carbon dioxide to the atmosphere. Then, bacteria and fungi, collectively called **decomposers**, carry out the breakdown (decomposition) of plants and animals and their organic compounds. The most important contributor of carbon dioxide to the atmosphere is microbial decomposition of dead material (dead animals, plants, and humus) that undergo respiration.

In aqueous environments and their anoxic sediments, there is another carbon cycle taking place. In this case, the cycle is based on one-carbon compounds. In anoxic sediments, prokaryotes, mostly archaea, produce methane ( $\text{CH}_4$ ). This methane moves into the zone above the sediment, which is richer in oxygen and supports bacteria called methane oxidizers that oxidize methane to carbon dioxide, which then returns to the atmosphere.

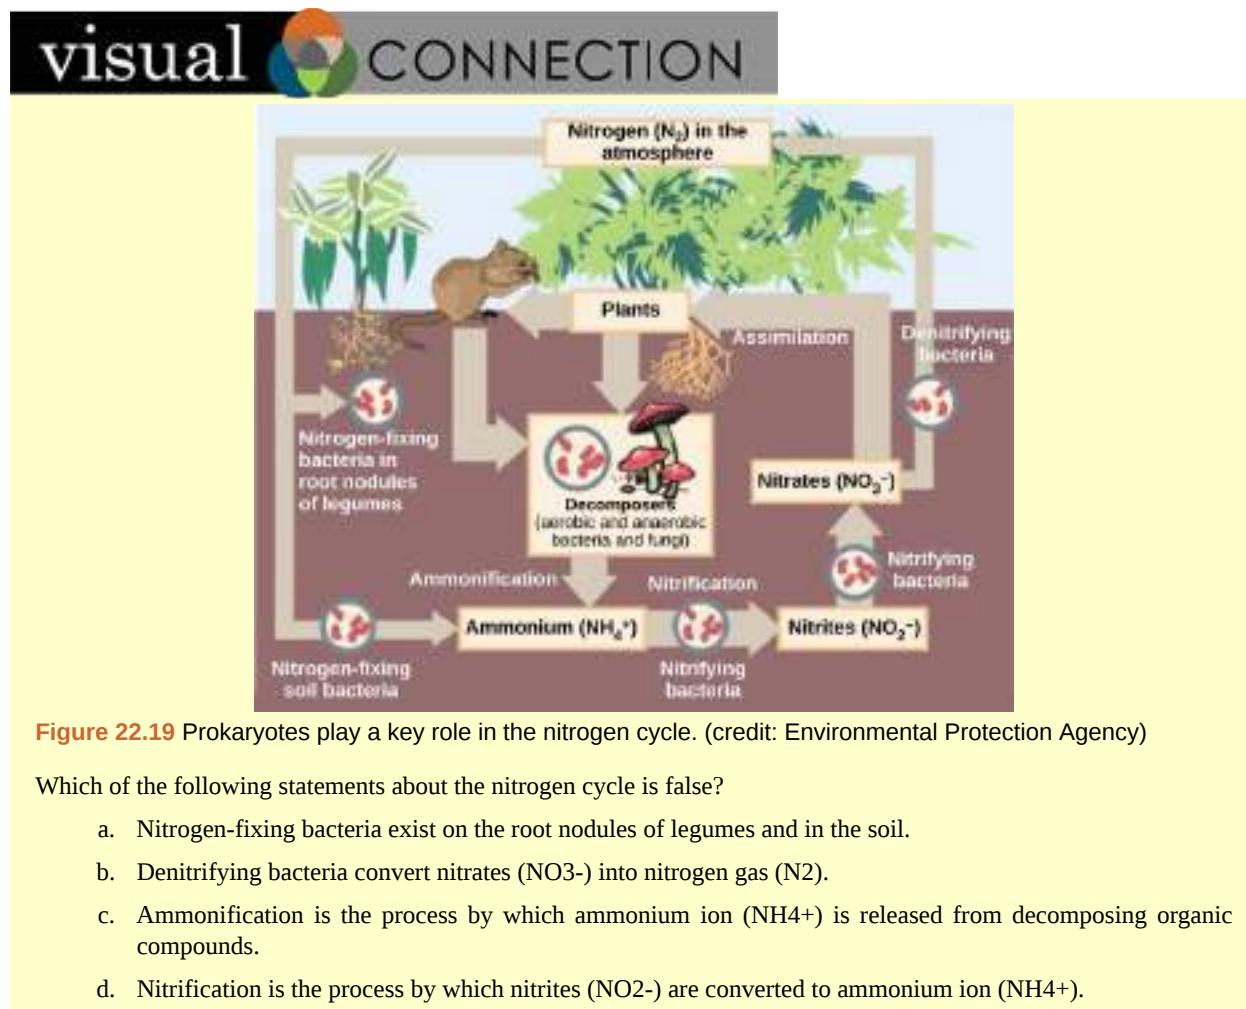

**Figure 22.18** Prokaryotes play a significant role in continuously moving carbon through the biosphere. (credit: modification of work by John M. Evans and Howard Perlman, USGS)

### Prokaryotes and the Nitrogen Cycle

Nitrogen is a very important element for life because it is part of proteins and nucleic acids. It is a macronutrient, and in nature, it is recycled from organic compounds to ammonia, ammonium ions, nitrate, nitrite, and nitrogen gas by myriad processes, many of which are carried out only by prokaryotes. As illustrated in [Figure 22.19](#), prokaryotes are key to the nitrogen cycle. The largest pool of nitrogen available in the terrestrial ecosystem is gaseous nitrogen from the air, but this nitrogen is not usable by plants, which are primary producers. Gaseous nitrogen is transformed, or “fixed” into more readily available forms such as ammonia through the process of **nitrogen fixation**. Ammonia can be used by plants or converted to other forms.

Another source of ammonia is **ammonification**, the process by which ammonia is released during the decomposition of nitrogen-containing organic compounds. Ammonia released to the atmosphere, however, represents only 15 percent of the total nitrogen released; the rest is as  $\text{N}_2$  and  $\text{N}_2\text{O}$ . Ammonia is catabolized anaerobically by some prokaryotes, yielding  $\text{N}_2$  as the final product. **Nitrification** is the conversion of ammonium to nitrite and nitrate. Nitrification in soils is carried out by bacteria belonging to the genera *Nitrosomas*, *Nitrobacter*, and *Nitrospira*. The bacteria performs the reverse process, the reduction of nitrate from the soils to gaseous compounds such as  $\text{N}_2\text{O}$ ,  $\text{NO}$ , and  $\text{N}_2$ , a process called **denitrification**.

## science practices CONNECTION for AP® Courses

### Think About It

Prokaryotes inhabit many diverse environments. Think about the conditions (temperature, light, pressure, and organic and inorganic materials) that you may find in a deep-sea hydrothermal vent. What types of prokaryotes, in terms of their metabolic needs (autotrophs, phototrophs, chemotrophs, and so on) would expect to find there? What features of these prokaryotes would make it possible for them to inhabit such an extreme environment?

## 22.4 | Bacterial Diseases in Humans

In this section, you will explore the following questions:

- What are examples of bacterial diseases that caused historically important plagues and epidemics?
- What are links between bacteria, especially in biofilms, and foodborne diseases?
- How can the overuse of antibiotics create “super bugs” such as MRSA?

## Connection for AP® Courses

Although many bacteria participate in mutualistic relationships with their hosts, others exist in parasitic relationships, causing disease. Many bacteria have evolved resistance to antibiotics, and scientists are developing new antibiotics that are effective against infections caused by emergent diseases. Examples of bacteria-caused infections include pneumonia, plague, typhoid, and Lyme disease. Although some diseases have been eradicated, the emergence of new infections, such as MRSA, provides evidence that evolution is an ongoing process. Epidemiologists study how disease affects a population.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 and Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 3.3][APLO 3.27][APLO 2.8][APLO 2.9][APLO 2.24][APLO 4.14][APLO 4.21]

Devastating pathogen-borne diseases and plagues, both viral and bacterial in nature, have affected humans since the beginning of human history. The true cause of these diseases was not understood at the time, and some people thought that diseases were a spiritual punishment. Over time, people came to realize that staying apart from afflicted persons, and disposing of the corpses and personal belongings of victims of illness, reduced their own chances of getting sick.

Epidemiologists study how diseases affect a population. An **epidemic** is a disease that occurs in an unusually high number of individuals in a population at the same time. A **pandemic** is a widespread, usually worldwide, epidemic. An **endemic disease** is a disease that is constantly present, usually at low incidence, in a population.

## Long History of Bacterial Disease

There are records about infectious diseases as far back as 3000 B.C. A number of significant pandemics caused by bacteria have been documented over several hundred years. Some of the most memorable pandemics led to the decline of cities and nations.

In the 21<sup>st</sup> century, infectious diseases remain among the leading causes of death worldwide, despite advances made in medical research and treatments in recent decades. A disease spreads when the pathogen that causes it is passed from one person to another. For a pathogen to cause disease, it must be able to reproduce in the host's body and damage the host in some way.

### The Plague of Athens

In 430 B.C., the Plague of Athens killed one-quarter of the Athenian troops that were fighting in the great Peloponnesian War and weakened Athens' dominance and power. The plague impacted people living in overcrowded Athens as well as troops aboard ships that had to return to Athens. The source of the plague may have been identified recently when researchers from the University of Athens were able to use DNA from teeth recovered from a mass grave. The scientists identified nucleotide sequences from a pathogenic bacterium, *Salmonella enterica* serovar Typhi (Figure 22.20), which causes typhoid fever.<sup>[3]</sup> This disease is commonly seen in overcrowded areas and has caused epidemics throughout recorded history.

**Figure 22.20** *Salmonella enterica* serovar Typhi, the causative agent of Typhoid fever, is a Gram-negative, rod-shaped gamma protobacterium. Typhoid fever, which is spread through feces, causes intestinal hemorrhage, high fever, delirium and dehydration. Today, between 16 and 33 million cases of this re-emerging disease occur annually, resulting in over 200,000 deaths. Carriers of the disease can be asymptomatic. In a famous case in the early 1900s, a cook named Mary Mallon unknowingly spread the disease to over fifty people, three of whom died. Other *Salmonella* serotypes cause food poisoning. (credit: modification of work by NCI, CDC)

### Bubonic Plagues

From 541 to 750, an outbreak of what was likely a bubonic plague (the Plague of Justinian), eliminated one-quarter to one-half of the human population in the eastern Mediterranean region. The population in Europe dropped by 50 percent during this outbreak. Bubonic would strike Europe more than once.

One of the most devastating pandemics was the **Black Death** (1346 to 1361) that is believed to have been another outbreak of bubonic plague caused by the bacterium *Yersinia pestis*. It is thought to have originated initially in China and spread along the Silk Road, a network of land and sea trade routes, to the Mediterranean region and Europe, carried by rat fleas living on black rats that were always present on ships. The Black Death reduced the world's population from an estimated 450 million to about 350 to 375 million. Bubonic plague struck London hard again in the mid-1600s (Figure 22.21). In modern times, approximately 1,000 to 3,000 cases of plague arise globally each year. Although contracting bubonic plague before antibiotics meant almost certain death, the bacterium responds to several types of modern antibiotics, and mortality rates from plague are now very low.

3. Papagrigorakis MJ, Synodinos PN, and Yapijkas C. Ancient typhoid epidemic reveals possible ancestral strain of *Salmonella enterica* serovar Typhi. *Infect Genet Evol* 7 (2007): 126–7, Epub 2006 Jun.

**Figure 22.21** The (a) Great Plague of London killed an estimated 200,000 people, or about twenty percent of the city's population. The causative agent, the (b) bacterium *Yersinia pestis*, is a Gram-negative, rod-shaped bacterium from the class Gamma Proteobacteria. The disease is transmitted through the bite of an infected flea, which is infected by a rodent. Symptoms include swollen lymph nodes, fever, seizure, vomiting of blood, and (c) gangrene. (credit b: Rocky Mountain Laboratories, NIAID, NIH; scale-bar data from Matt Russell; credit c: Textbook of Military Medicine, Washington, D.C., U.S. Dept. of the Army, Office of the Surgeon General, Borden Institute)

Watch a [video](http://openstaxcollege.org/l/black_death) ([http://openstaxcollege.org/l/black\\_death](http://openstaxcollege.org/l/black_death)) on the modern understanding of the Black Death—bubonic plague in Europe during the 14<sup>th</sup> century.

How were researchers able to use modern science to determine the agent of disease for the bubonic plague of the 14th century?

- The amino acid sequence of proteins, extracted from the samples taken from skeletons buried in a cemetery from the 14th century, was constructed and compared to that of modern strain of the bacterium *Y. enterocolitica* and found a close match.
- The genomic sequence of the DNA, extracted from the samples taken from skeletons buried in a cemetery from the 14th century, was constructed and compared to that of modern strain of the bacterium *Y. enterocolitica* and found a close match.
- The gene sequence of 16S rRNA, extracted from the samples taken from skeletons buried in a cemetery from the 14th century, was constructed and compared to that of modern strain of the bacterium *Y. pestis* and found a close match.
- The genomic sequence of the DNA, extracted from the samples taken from skeletons buried in a cemetery from the 14th century, was constructed and compared to that of modern strain of the bacterium *Y. pestis* and found a close match.

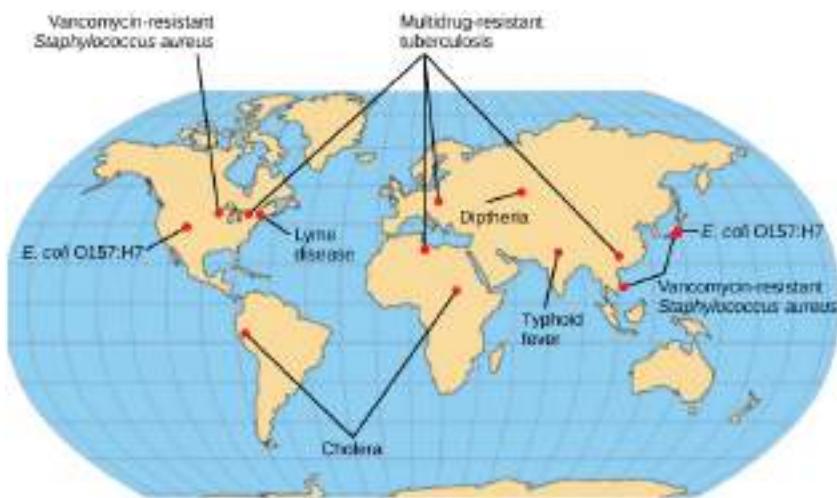

### Migration of Diseases to New Populations

Over the centuries, Europeans tended to develop genetic immunity to endemic infectious diseases, but when European conquerors reached the western hemisphere, they brought with them disease-causing bacteria and viruses, which triggered epidemics that completely devastated populations of Native Americans, who had no natural resistance to many European diseases. It has been estimated that up to 90 percent of Native Americans died from infectious diseases after the arrival of Europeans, making conquest of the New World a foregone conclusion.

### Emerging and Re-emerging Diseases

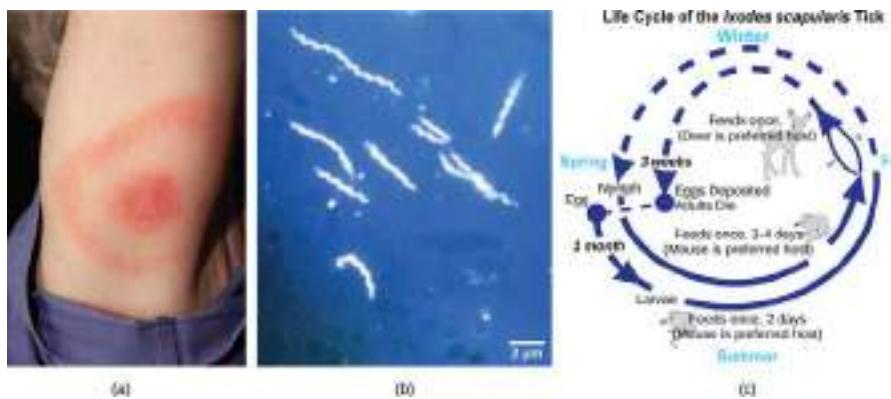

The distribution of a particular disease is dynamic. Therefore, changes in the environment, the pathogen, or the host

population can dramatically impact the spread of a disease. According to the World Health Organization (WHO) an **emerging disease** (Figure 22.22) is one that has appeared in a population for the first time, or that may have existed previously but is rapidly increasing in incidence or geographic range. This definition also includes re-emerging diseases that were previously under control. Approximately 75 percent of recently emerging infectious diseases affecting humans are zoonotic diseases, **zoonoses**, diseases that primarily infect animals and are transmitted to humans; some are of viral origin and some are of bacterial origin. Brucellosis is an example of a prokaryotic zoonosis that is re-emerging in some regions, and necrotizing fasciitis (commonly known as flesh-eating bacteria) has been increasing in virulence for the last 80 years for unknown reasons.

**Figure 22.22** The map shows regions where bacterial diseases are emerging or reemerging. (credit: modification of work by NIH)

Some of the present emerging diseases are not actually new, but are diseases that were catastrophic in the past (Figure 22.23). They devastated populations and became dormant for a while, just to come back, sometimes more virulent than before, as was the case with bubonic plague. Other diseases, like tuberculosis, were never eradicated but were under control in some regions of the world until coming back, mostly in urban centers with high concentrations of immunocompromised people. The WHO has identified certain diseases whose worldwide re-emergence should be monitored. Among these are two viral diseases (dengue fever and yellow fever), and three bacterial diseases (diphtheria, cholera, and bubonic plague). The war against infectious diseases has no foreseeable end.

**Figure 22.23** Lyme disease often, but not always, results in (a) a characteristic bullseye rash. The disease is caused by a (b) Gram-negative spirochete bacterium of the genus *Borrelia*. The bacteria (c) infect ticks, which in turn infect mice. Deer are the preferred secondary host, but the ticks also may feed on humans. Untreated, the disease causes chronic disorders in the nervous system, eyes, joints, and heart. The disease is named after Lyme, Connecticut, where an outbreak occurred in 1995 and has subsequently spread. The disease is not new, however. Genetic evidence suggests that Ötzi the Iceman, a 5,300-year-old mummy found in the Alps, was infected with *Borrelia*. (credit a: James Gathany, CDC; credit b: CDC; scale-bar data from Matt Russell)

## Biofilms and Disease

Recall that biofilms are microbial communities that are very difficult to destroy. They are responsible for diseases such as

infections in patients with cystic fibrosis, Legionnaires' disease, and otitis media. They produce dental plaque and colonize catheters, prostheses, transcutaneous and orthopedic devices, contact lenses, and internal devices such as pacemakers. They also form in open wounds and burned tissue. In healthcare environments, biofilms grow on hemodialysis machines, mechanical ventilators, shunts, and other medical equipment. In fact, 65 percent of all infections acquired in the hospital (nosocomial infections) are attributed to biofilms. Biofilms are also related to diseases contracted from food because they colonize the surfaces of vegetable leaves and meat, as well as food-processing equipment that isn't adequately cleaned.

Biofilm infections develop gradually; sometimes, they do not cause symptoms immediately. They are rarely resolved by host defense mechanisms. Once an infection by a biofilm is established, it is very difficult to eradicate, because biofilms tend to be resistant to most of the methods used to control microbial growth, including antibiotics. Biofilms respond poorly or only temporarily to antibiotics; it has been said that they can resist up to 1,000 times the antibiotic concentrations used to kill the same bacteria when they are free-living or planktonic. An antibiotic dose that large would harm the patient; therefore, scientists are working on new ways to get rid of biofilms.

## Antibiotics: Are We Facing a Crisis?

The word *antibiotic* comes from the Greek *anti* meaning "against" and *bios* meaning "life." An **antibiotic** is a chemical, produced either by microbes or synthetically, that is hostile to the growth of other organisms. Today's news and media often address concerns about an antibiotic crisis. Are the antibiotics that easily treated bacterial infections in the past becoming obsolete? Are there new "superbugs"—bacteria that have evolved to become more resistant to our arsenal of antibiotics? Is this the beginning of the end of antibiotics? All these questions challenge the healthcare community.

One of the main causes of resistant bacteria is the abuse of antibiotics. The imprudent and excessive use of antibiotics has resulted in the natural selection of resistant forms of bacteria. The antibiotic kills most of the infecting bacteria, and therefore only the resistant forms remain. These resistant forms reproduce, resulting in an increase in the proportion of resistant forms over non-resistant ones. Another major misuse of antibiotics is in patients with colds or the flu, for which antibiotics are useless. Another problem is the excessive use of antibiotics in livestock. The routine use of antibiotics in animal feed promotes bacterial resistance as well. In the United States, 70 percent of the antibiotics produced are fed to animals. These antibiotics are given to livestock in low doses, which maximize the probability of resistance developing, and these resistant bacteria are readily transferred to humans.

Visit [this site](http://openstaxcollege.org/l/antibiotics) (<http://openstaxcollege.org/l/antibiotics>) to learn more about the problem of routine antibiotic administration to livestock and antibiotic-resistant bacteria.

In your own words, what is the problem with administering antibiotics to livestock when they are not in need of them?

- Development of antibiotic-susceptible bacteria that can be transferred to humans, and their presence makes treatment of disease with antibiotics (in animals or humans) much more difficult.
- Development of antibiotic-resistant bacteria that cannot be transferred to humans, and their presence makes treatment of disease with antibiotics (in animals or humans) much more difficult.
- Development of antibiotic-resistant bacteria that can be transferred to humans, and their presence makes treatment of disease with antibiotics (in animals or humans) much more difficult.
- Development of antibiotic-susceptible bacteria that cannot be transferred to humans, and their presence makes treatment of disease with antibiotics (in animals or humans) much more difficult.

### One of the Superbugs: MRSA

The imprudent use of antibiotics has paved the way for bacteria to expand populations of resistant forms. For example, *Staphylococcus aureus*, often called "staph," is a common bacterium that can live in the human body and is usually easily treated with antibiotics. A very dangerous strain, however, **methicillin-resistant *Staphylococcus aureus* (MRSA)**

has made the news over the past few years ([Figure 22.24](#)). This strain is resistant to many commonly used antibiotics, including methicillin, amoxicillin, penicillin, and oxacillin. MRSA can cause infections of the skin, but it can also infect the bloodstream, lungs, urinary tract, or sites of injury. While MRSA infections are common among people in healthcare facilities, they have also appeared in healthy people who haven't been hospitalized but who live or work in tight populations (like military personnel and prisoners). Researchers have expressed concern about the way this latter source of MRSA targets a much younger population than those residing in care facilities. *The Journal of the American Medical Association* reported that, among MRSA-afflicted persons in healthcare facilities, the average age is 68, whereas people with "community-associated MRSA" (CA-MRSA) have an average age of 23.<sup>[4]</sup>

**Figure 22.24** This scanning electron micrograph shows methicillin-resistant *Staphylococcus aureus* bacteria, commonly known as MRSA. *S. aureus* is not always pathogenic, but can cause diseases such as food poisoning and skin and respiratory infections. (credit: modification of work by Janice Haney Carr; scale-bar data from Matt Russell)

In summary, the medical community is facing an antibiotic crisis. Some scientists believe that after years of being protected from bacterial infections by antibiotics, we may be returning to a time in which a simple bacterial infection could again devastate the human population. Researchers are developing new antibiotics, but it takes many years to of research and clinical trials, plus financial investments in the millions of dollars, to generate an effective and approved drug.

## Foodborne Diseases

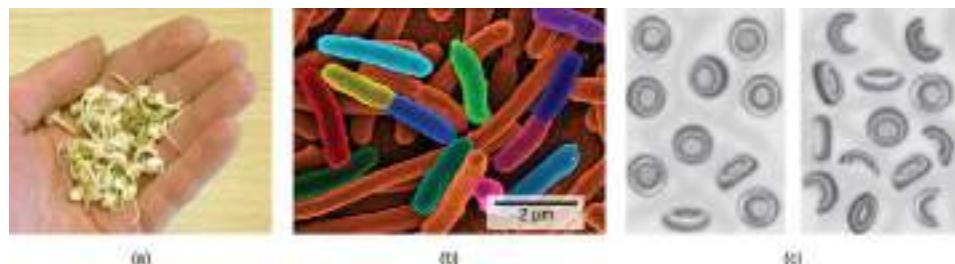

Prokaryotes are everywhere: They readily colonize the surface of any type of material, and food is not an exception. Most of the time, prokaryotes colonize food and food-processing equipment in the form of a biofilm. Outbreaks of bacterial infection related to food consumption are common. A **foodborne disease** (colloquially called "food poisoning") is an illness resulting from the consumption the pathogenic bacteria, viruses, or other parasites that contaminate food. Although the United States has one of the safest food supplies in the world, the U.S. Centers for Disease Control and Prevention (CDC) has reported that "76 million people get sick, more than 300,000 are hospitalized, and 5,000 Americans die each year from foodborne illness."

The characteristics of foodborne illnesses have changed over time. In the past, it was relatively common to hear about sporadic cases of **botulism**, the potentially fatal disease produced by a toxin from the anaerobic bacterium *Clostridium botulinum*. Some of the most common sources for this bacterium were non-acidic canned foods, homemade pickles, and processed meat and sausages. The can, jar, or package created a suitable anaerobic environment where *Clostridium* could grow. Proper sterilization and canning procedures have reduced the incidence of this disease.

While people may tend to think of foodborne illnesses as associated with animal-based foods, most cases are now linked to produce. There have been serious, produce-related outbreaks associated with raw spinach in the United States and with vegetable sprouts in Germany, and these types of outbreaks have become more common. The raw spinach outbreak in 2006 was produced by the bacterium *E. coli* serotype O157:H7. A **serotype** is a strain of bacteria that carries a set of similar antigens on its cell surface, and there are often many different serotypes of a bacterial species. Most *E. coli* are not particularly dangerous to humans, but serotype O157:H7 can cause bloody diarrhea and is potentially fatal.

All types of food can potentially be contaminated with bacteria. Recent outbreaks of *Salmonella* reported by the CDC occurred in foods as diverse as peanut butter, alfalfa sprouts, and eggs. A deadly outbreak in Germany in 2010 was caused by *E. coli* contamination of vegetable sprouts ([Figure 22.25](#)). The strain that caused the outbreak was found to be a new serotype not previously involved in other outbreaks, which indicates that *E. coli* is continuously evolving.

4. Naimi, TS, LeDell, KH, Como-Sabetti, K, et al. Comparison of community- and health care-associated methicillin-resistant *Staphylococcus aureus* infection. *JAMA* 290 (2003): 2976–84, doi: 10.1001/jama.290.22.2976.

**Figure 22.25** (a) Vegetable sprouts grown at an organic farm were the cause of an (b) *E. coli* outbreak that killed 32 people and sickened 3,800 in Germany in 2011. The strain responsible, *E. coli* O104:H4, produces Shiga toxin, a substance that inhibits protein synthesis in the host cell. The toxin (c) destroys red blood cells resulting in bloody diarrhea. Deformed red blood cells clog the capillaries of the kidney, which can lead to kidney failure, as happened to 845 patients in the 2011 outbreak. Kidney failure is usually reversible, but some patients experience kidney problems years later. (credit c: NIDDK, NIH)

## career CONNECTION

### Epidemiologist

Epidemiology is the study of the occurrence, distribution, and determinants of health and disease in a population. It is, therefore, part of public health. An epidemiologist studies the frequency and distribution of diseases within human populations and environments.

Epidemiologists collect data about a particular disease and track its spread to identify the original mode of transmission. They sometimes work in close collaboration with historians to try to understand the way a disease evolved geographically and over time, tracking the natural history of pathogens. They gather information from clinical records, patient interviews, surveillance, and any other available means. That information is used to develop strategies, such as vaccinations (**Figure 22.26**), and design public health policies to reduce the incidence of a disease or to prevent its spread. Epidemiologists also conduct rapid investigations in case of an outbreak to recommend immediate measures to control it.

An epidemiologist has a bachelor's degree, plus a master's degree in public health (MPH). Many epidemiologists are also physicians (and have an M.D.), or they have a Ph.D. in an associated field, such as biology or microbiology.

**Figure 22.26** Vaccinations can slow the spread of communicable diseases. (credit: modification of work by Daniel Paquet)

### Think About It

How can a strain of bacteria that was previously sensitive to an antibiotic become resistant to the same antibiotic? Why has this become a major global problem?

## 22.5 | Beneficial Prokaryotes

In this section, you will explore the following questions:

- What is the need for nitrogen fixation and how is it accomplished?
- What are examples of foods for which prokaryotes are used in processing?
- What is bioremediation and how do prokaryotes play a role in this process?

### Connection for AP® Courses

We commonly think of pathogens when we think of prokaryotes, focusing on their relationship with disease. However, most prokaryotes do not cause disease and they play a wide range of other roles in ecosystems. Nitrogen needed to synthesize proteins and nucleic acids is often the most limiting element in ecosystems and bacteria are able to “fix” nitrogen into forms that can be used by eukaryotes. Microbes also are used to remove pollutants from environments, a process called **bioremediation**. Microbes that call us home are necessary for our survival. They help us digest our food, produce crucial nutrients, protect us from pathogenic microbes, and help train our immune system to function correctly. In addition, without prokaryotes we wouldn’t have cheese, bread, wine, beer, and yogurt.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 2.6][APLO 2.28][APLO 2.42][APLO 4.9][APLO 4.1]

Not all prokaryotes are pathogenic. On the contrary, pathogens represent only a very small percentage of the diversity of the microbial world. In fact, our life would not be possible without prokaryotes. Just think about the role of prokaryotes in biogeochemical cycles.

## Cooperation between Bacteria and Eukaryotes: Nitrogen Fixation

Nitrogen is a very important element to living things, because it is part of nucleotides and amino acids that are the building blocks of nucleic acids and proteins, respectively. Nitrogen is usually the most limiting element in terrestrial ecosystems, with atmospheric nitrogen, N<sub>2</sub>, providing the largest pool of available nitrogen. However, eukaryotes cannot use atmospheric, gaseous nitrogen to synthesize macromolecules. Fortunately, nitrogen can be “fixed,” meaning it is converted into ammonia (NH<sub>3</sub>) either biologically or abiotically. Abiotic nitrogen fixation occurs as a result of lightning or by industrial processes.

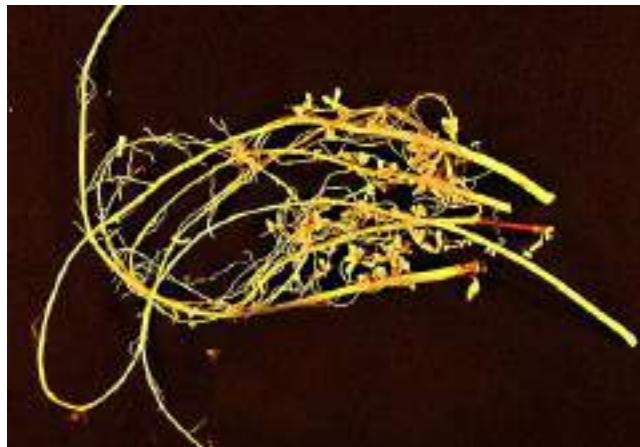

**Biological nitrogen fixation** (BNF) is exclusively carried out by prokaryotes: soil bacteria, cyanobacteria, and *Frankia* spp. (filamentous bacteria interacting with actinorhizal plants such as alder, bayberry, and sweet fern). After photosynthesis, BNF is the second most important biological process on Earth. The equation representing the process is as follows

where Pi stands for inorganic phosphate. The total fixed nitrogen through BNF is about 100 to 180 million metric tons per year. Biological processes contribute 65 percent of the nitrogen used in agriculture.

Cyanobacteria are the most important nitrogen fixers in aquatic environments. In soil, members of the genus *Clostridium* are examples of free-living, nitrogen-fixing bacteria. Other bacteria live symbiotically with legume plants, providing the most important source of BNF. Symbionts may fix more nitrogen in soils than free-living organisms by a factor of 10. Soil bacteria, collectively called rhizobia, are able to symbiotically interact with legumes to form **nodules**, specialized structures where nitrogen fixation occurs (Figure 22.27). Nitrogenase, the enzyme that fixes nitrogen, is inactivated by oxygen, so the nodule provides an oxygen-free area for nitrogen fixation to take place. This process provides a natural and inexpensive plant fertilizer, as it reduces atmospheric nitrogen to ammonia, which is easily usable by plants. The use of legumes is an excellent alternative to chemical fertilization and is of special interest to sustainable agriculture, which seeks to minimize the use of chemicals and conserve natural resources. Through symbiotic nitrogen fixation, the plant benefits from using an endless source of nitrogen: the atmosphere. Bacteria benefit from using photosynthates (carbohydrates produced during photosynthesis) from the plant and having a protected niche. Additionally, the soil benefits from being naturally fertilized. Therefore, the use of rhizobia as biofertilizers is a sustainable practice.

Why are legumes so important? Some, like soybeans, are key sources of agricultural protein. Some of the most important grain legumes are soybean, peanuts, peas, chickpeas, and beans. Other legumes, such as alfalfa, are used to feed cattle.

**Figure 22.27** Soybean (*Glycine max*) is a legume that interacts symbiotically with the soil bacterium *Bradyrhizobium japonicum* to form specialized structures on the roots called nodules where nitrogen fixation occurs. (credit: USDA)

## Early Biotechnology: Cheese, Bread, and Yogurt

According to the United Nations Convention on Biological Diversity, **biotechnology** is “any technological application that uses biological systems, living organisms, or derivatives thereof, to make or modify products or processes for specific use.”<sup>5</sup> The concept of “specific use” involves some sort of commercial application. Genetic engineering, artificial selection, antibiotic production, and cell culture are current topics of study in biotechnology. However, humans have used prokaryotes before the term biotechnology was even coined. In addition, some of the goods and services are as simple as cheese, bread, and yogurt, which employ both bacteria and other microbes, such as yeast, a fungus.

5. <http://www.cbd.int/convention/articles/?a=cbd-02>, United Nations Convention on Biological Diversity: Article 2: Use of Terms.

Cheese production began around 4,000–7,000 years ago when humans began to breed animals and process their milk. Fermentation in this case preserves nutrients: Milk will spoil relatively quickly, but when processed as cheese, it is more stable. Evidence suggests that cultured milk products, like yogurt, have existed for at least 4,000 years.

## Using Prokaryotes to Clean up Our Planet: Bioremediation

Microbial **bioremediation** is the use of prokaryotes (or microbial metabolism) to remove pollutants. Bioremediation has been used to remove agricultural chemicals (pesticides, fertilizers) that leach from soil into groundwater and the subsurface. Certain toxic metals and oxides, such as selenium and arsenic compounds, can also be removed from water by bioremediation. The reduction of  $\text{SeO}_4^{2-}$  to  $\text{SeO}_3^{2-}$  and to  $\text{Se}^0$  (metallic selenium) is a method used to remove selenium ions from water. Mercury is an example of a toxic metal that can be removed from an environment by bioremediation. As an active ingredient of some pesticides, mercury is used in industry and is also a by-product of certain processes, such as battery production. Methyl mercury is usually present in very low concentrations in natural environments, but it is highly toxic because it accumulates in living tissues. Several species of bacteria can carry out the biotransformation of toxic mercury into nontoxic forms. These bacteria, such as *Pseudomonas aeruginosa*, can convert  $\text{Hg}^{+2}$  into  $\text{Hg}^0$ , which is nontoxic to humans.

One of the most useful and interesting examples of the use of prokaryotes for bioremediation purposes is the cleanup of oil spills. The importance of prokaryotes to petroleum bioremediation has been demonstrated in several oil spills in recent years, such as the Exxon Valdez spill in Alaska (1989) (Figure 22.28), the Prestige oil spill in Spain (2002), the spill into the Mediterranean from a Lebanon power plant (2006), and more recently, the Deepwater Horizon oil spill in the Gulf of Mexico (2010). To clean up these spills, bioremediation is promoted by the addition of inorganic nutrients that help bacteria to grow. Hydrocarbon-degrading bacteria feed on hydrocarbons in the oil droplet, breaking down the hydrocarbons. Some species, such as *Alcanivorax borkumensis*, produce surfactants that solubilize the oil, whereas other bacteria degrade the oil into carbon dioxide. In the case of oil spills in the ocean, ongoing, natural bioremediation tends to occur, inasmuch as there are oil-consuming bacteria in the ocean prior to the spill. In addition to naturally occurring oil-degrading bacteria, humans select and engineer bacteria that possess the same capability with increased efficacy and spectrum of hydrocarbon compounds that can be processed. Under ideal conditions, it has been reported that up to 80 percent of the nonvolatile components in oil can be degraded within one year of the spill. Other oil fractions containing aromatic and highly branched hydrocarbon chains are more difficult to remove and remain in the environment for longer periods of time.

**Figure 22.28** (a) Cleaning up oil after the Valdez spill in Alaska, workers hosed oil from beaches and then used a floating boom to corral the oil, which was finally skimmed from the water surface. Some species of bacteria are able to solubilize and degrade the oil. (b) One of the most catastrophic consequences of oil spills is the damage to fauna. (credit a: modification of work by NOAA; credit b: modification of work by GOLUBENKOV, NGO: Saving Taman)

## everyday CONNECTION for AP<sup>®</sup> Courses

A particularly fascinating example of our normal flora relates to our digestive systems. People who take high doses of antibiotics tend to lose many of their normal gut bacteria, allowing a naturally antibiotic-resistant species called *Clostridium difficile* to overgrow and cause severe gastric problems, especially chronic diarrhea. Obviously, trying to treat this problem with antibiotics only makes it worse. However, it has been successfully treated by giving the patients fecal transplants from healthy donors to reestablish the normal intestinal microbial community. Scientists are also discovering that the absence of certain key microbes from our intestinal tract may set us up for a variety of problems including obesity, insulin resistance, and autoimmune disorders. Pictured here is a scanning electron micrograph of *Clostridium difficile*, a Gram-positive, rod-shaped bacterium that causes severe diarrhea. Infection commonly occurs after the normal gut fauna is eradicated by antibiotics.

**Figure 22.29** (credit: modification of work by CDC, HHS; scale-bar data from Matt Russell)

What treatment is possible for people who have too much *C. difficile* in their digestive system?

- By taking antibiotics like metronidazole as treatment.
- They can have a fecal transplant from a healthy donor.
- They can have urine transplant from a healthy donor.
- By taking probiotic supplements to restore microbial intestinal community.

## science practices CONNECTION for AP<sup>®</sup> Courses

### Think About It

One of your classmates claims that prokaryotes are always detrimental and pathogenic. How would you explain to him that his claim is incorrect?

## KEY TERMS

**acidophile** organism with optimal growth pH of three or below

**alkaliphile** organism with optimal growth pH of nine or above

**ammonification** process by which ammonia is released during the decomposition of nitrogen-containing organic compounds

**anaerobic** refers to organisms that grow without oxygen

**anoxic** without oxygen

**antibiotic** biological substance that, in low concentration, is antagonistic to the growth of prokaryotes

**biofilm** microbial community that is held together by a gummy-textured matrix

**biological nitrogen fixation** conversion of atmospheric nitrogen into ammonia exclusively carried out by prokaryotes

**bioremediation** use of microbial metabolism to remove pollutants

**biotechnology** any technological application that uses living organisms, biological systems, or their derivatives to produce or modify other products

**Black Death** devastating pandemic that is believed to have been an outbreak of bubonic plague caused by the bacterium *Yersinia pestis*

**botulism** disease produced by the toxin of the anaerobic bacterium *Clostridium botulinum*

**CA-MRSA** MRSA acquired in the community rather than in a hospital setting

**capsule** external structure that enables a prokaryote to attach to surfaces and protects it from dehydration

**chemotroph** organism that obtains energy from chemical compounds

**conjugation** process by which prokaryotes move DNA from one individual to another using a pilus

**cyanobacteria** bacteria that evolved from early phototrophs and oxygenated the atmosphere; also known as blue-green algae

**decomposer** organism that carries out the decomposition of dead organisms

**denitrification** transformation of nitrate from soil to gaseous nitrogen compounds such as N<sub>2</sub>O, NO and N<sub>2</sub>

**emerging disease** disease making an initial appearance in a population or that is increasing in incidence or geographic range

**endemic disease** disease that is constantly present, usually at low incidence, in a population

**epidemic** disease that occurs in an unusually high number of individuals in a population at the same time

**extremophile** organism that grows under extreme or harsh conditions

**foodborne disease** any illness resulting from the consumption of contaminated food, or of the pathogenic bacteria, viruses, or other parasites that contaminate food

**Gram negative** bacterium whose cell wall contains little peptidoglycan but has an outer membrane

**Gram positive** bacterium that contains mainly peptidoglycan in its cell walls

**halophile** organism that requires a salt concentration of at least 0.2 M

**hydrothermal vent** fissure in Earth's surface that releases geothermally heated water

**hyperthermophile** organism that grows at temperatures between 80–122 °C

**microbial mat** multi-layered sheet of prokaryotes that may include bacteria and archaea

**MRSA** (methicillin-resistant *Staphylococcus aureus*) very dangerous *Staphylococcus aureus* strain resistant to multiple antibiotics

**nitrification** conversion of ammonium into nitrite and nitrate in soils

**nitrogen fixation** process by which gaseous nitrogen is transformed, or “fixed” into more readily available forms such as ammonia

**nodule** novel structure on the roots of certain plants (legumes) that results from the symbiotic interaction between the plant and soil bacteria, is the site of nitrogen fixation

**nutrient** essential substances for growth, such as carbon and nitrogen

**osmophile** organism that grows in a high sugar concentration

**pandemic** widespread, usually worldwide, epidemic disease

**peptidoglycan** material composed of polysaccharide chains cross-linked to unusual peptides

**phototroph** organism that is able to make its own food by converting solar energy to chemical energy

**pilus** surface appendage of some prokaryotes used for attachment to surfaces including other prokaryotes

**pseudopeptidoglycan** component of archaea cell walls that is similar to peptidoglycan in morphology but contains different sugars

**psychrophile** organism that grows at temperatures of –15 °C or lower

**radioresistant** organism that grows in high levels of radiation

**resuscitation** process by which prokaryotes that are in the VBNC state return to viability

**S-layer** surface-layer protein present on the outside of cell walls of archaea and bacteria

**serotype** strain of bacteria that carries a set of similar antigens on its cell surface, often many in a bacterial species

**stromatolite** layered sedimentary structure formed by precipitation of minerals by prokaryotes in microbial mats

**teichoic acid** polymer associated with the cell wall of Gram-positive bacteria

**thermophile** organism that lives at temperatures between 60–80 °C

**transduction** process by which a bacteriophage moves DNA from one prokaryote to another

**transformation** process by which a prokaryote takes in DNA found in its environment that is shed by other prokaryotes

**viable-but-non-culturable (VBNC) state** survival mechanism of bacteria facing environmental stress conditions

**zoonosis** disease that primarily infects animals that is transmitted to humans

## CHAPTER SUMMARY

### 22.1 Prokaryotic Diversity

Prokaryotes existed for billions of years before plants and animals appeared. Hot springs and hydrothermal vents may have been the environments in which life began. Microbial mats are thought to represent the earliest forms of life on Earth, and there is fossil evidence of their presence about 3.5 billion years ago. A microbial mat is a multi-layered sheet of prokaryotes that grows at interfaces between different types of material, mostly on moist surfaces. During the first 2 billion years, the atmosphere was anoxic and only anaerobic organisms were able to live. Cyanobacteria evolved from early

phototrophs and began the oxygenation of the atmosphere. The increase in oxygen concentration allowed the evolution of other life forms. Fossilized microbial mats are called stromatolites and consist of laminated organo-sedimentary structures formed by precipitation of minerals by prokaryotes. They represent the earliest fossil record of life on Earth.

Bacteria and archaea grow in virtually every environment. Those that survive under extreme conditions are called extremophiles (extreme lovers). Some prokaryotes cannot grow in a laboratory setting, but they are not dead. They are in the viable-but-non-cultivable (VBNC) state. The VBNC state occurs when prokaryotes enter a dormant state in response to environmental stressors. Most prokaryotes are social and prefer to live in communities where interactions take place. A biofilm is a microbial community held together in a gummy-textured matrix.

## 22.2 Structure of Prokaryotes

Prokaryotes (domains Archaea and Bacteria) are single-celled organisms lacking a nucleus. They have a single piece of circular DNA in the nucleoid area of the cell. Most prokaryotes have a cell wall that lies outside the boundary of the plasma membrane. Some prokaryotes may have additional structures such as a capsule, flagella, and pili. Bacteria and Archaea differ in the lipid composition of their cell membranes and the characteristics of the cell wall. In archaeal membranes, phytanyl units, rather than fatty acids, are linked to glycerol. Some archaeal membranes are lipid monolayers instead of bilayers.

The cell wall is located outside the cell membrane and prevents osmotic lysis. The chemical composition of cell walls varies between species. Bacterial cell walls contain peptidoglycan. Archaean cell walls do not have peptidoglycan, but they may have pseudopeptidoglycan, polysaccharides, glycoproteins, or protein-based cell walls. Bacteria can be divided into two major groups: Gram positive and Gram negative, based on the Gram stain reaction. Gram-positive organisms have a thick cell wall, together with teichoic acids. Gram-negative organisms have a thin cell wall and an outer envelope containing lipopolysaccharides and lipoproteins.

## 22.3 Prokaryotic Metabolism

Prokaryotes are the most metabolically diverse organisms; they flourish in many different environments with various carbon energy and carbon sources, variable temperature, pH, pressure, and water availability. Nutrients required in large amounts are called macronutrients, whereas those required in trace amounts are called micronutrients or trace elements. Macronutrients include C, H, O, N, P, S, K, Mg, Ca, and Na. In addition to these macronutrients, prokaryotes require various metallic elements for growth and enzyme function. Prokaryotes use different sources of energy to assemble macromolecules from smaller molecules. Phototrophs obtain their energy from sunlight, whereas chemotrophs obtain energy from chemical compounds.

Prokaryotes play roles in the carbon and nitrogen cycles. Carbon is returned to the atmosphere by the respiration of animals and other chemoorganotrophic organisms. Consumers use organic compounds generated by producers and release carbon dioxide into the atmosphere. The most important contributor of carbon dioxide to the atmosphere is microbial decomposition of dead material. Nitrogen is recycled in nature from organic compounds to ammonia, ammonium ions, nitrite, nitrate, and nitrogen gas. Gaseous nitrogen is transformed into ammonia through nitrogen fixation. Ammonia is anaerobically catabolized by some prokaryotes, yielding  $N_2$  as the final product. Nitrification is the conversion of ammonium into nitrite. Nitrification in soils is carried out by bacteria. Denitrification is also performed by bacteria and transforms nitrate from soils into gaseous nitrogen compounds, such as  $N_2O$ , NO, and  $N_2$ .

## 22.4 Bacterial Diseases in Humans

Devastating diseases and plagues have been among us since early times. There are records about microbial diseases as far back as 3000 B.C. Infectious diseases remain among the leading causes of death worldwide. Emerging diseases are those rapidly increasing in incidence or geographic range. They can be new or re-emerging diseases (previously under control). Many emerging diseases affecting humans, such as brucellosis, are zoonoses. The WHO has identified a group of diseases whose re-emergence should be monitored: Those caused by bacteria include bubonic plague, diphtheria, and cholera.

Biofilms are considered responsible for diseases such as bacterial infections in patients with cystic fibrosis, Legionnaires' disease, and otitis media. They produce dental plaque; colonize catheters, prostheses, transcutaneous, and orthopedic devices; and infect contact lenses, open wounds, and burned tissue. Biofilms also produce foodborne diseases because they colonize the surfaces of food and food-processing equipment. Biofilms are resistant to most of the methods used to control microbial growth. The excessive use of antibiotics has resulted in a major global problem, since resistant forms of bacteria have been selected over time. A very dangerous strain, methicillin-resistant *Staphylococcus aureus* (MRSA), has wreaked havoc recently. Foodborne diseases result from the consumption of contaminated food, pathogenic bacteria, viruses, or parasites that contaminate food.

## 22.5 Beneficial Prokaryotes

Pathogens are only a small percentage of all prokaryotes. In fact, our life would not be possible without prokaryotes. Nitrogen is usually the most limiting element in terrestrial ecosystems; atmospheric nitrogen, the largest pool of available nitrogen, is unavailable to eukaryotes. Nitrogen can be “fixed,” or converted into ammonia ( $\text{NH}_3$ ) either biologically or abiotically. Biological nitrogen fixation (BNF) is exclusively carried out by prokaryotes. After photosynthesis, BNF is the second most important biological process on Earth. The most important source of BNF is the symbiotic interaction between soil bacteria and legume plants.

Microbial bioremediation is the use of microbial metabolism to remove pollutants. Bioremediation has been used to remove agricultural chemicals that leach from soil into groundwater and the subsurface. Toxic metals and oxides, such as selenium and arsenic compounds, can also be removed by bioremediation. Probably one of the most useful and interesting examples of the use of prokaryotes for bioremediation purposes is the cleanup of oil spills.

Human life is only possible due to the action of microbes, both those in the environment and those species that call us home. Internally, they help us digest our food, produce crucial nutrients for us, protect us from pathogenic microbes, and help train our immune systems to function correctly.

## REVIEW QUESTIONS

1. Which is the best evidence that prokaryotes evolved about 3 billion years ago?
  - a. Scientists believe photosynthesis evolved about 3.0 billion years ago.
  - b. There is fossil evidence of mammalian forms going back about 4.0 billion years.
  - c. Earth and its moon are thought to be about 4.5 billion years old.
  - d. There is fossil evidence of microbial mats—large multi-layered sheets of prokaryotes—starting about 3.5 billion years ago.
2. Which statement describing the environment of early Earth is false?
  - a. The atmosphere contained much less molecular oxygen.
  - b. Strong volcanic activity was common.
  - c. It was subject to mutagenic radiation from the Sun.
  - d. There was little to no geologic activity.
3. Which type of extremophile grows optimally at temperatures of  $-15$  to  $10$  °C or lower?
  - a. alkaliphiles
  - b. thermophiles
  - c. hyperthermophiles
  - d. psychrophiles
4. Which is an example of a relatively moderate environmental condition to which some prokaryotes are adapted and can survive as spores?
  - a. extremely low temperature
  - b. hypersalinity
  - c. high doses of radiation
  - d. normal drought
5. Over \_\_\_\_\_ percent of bacteria and archaea cannot be successfully cultured in a laboratory setting.
  - a. 9
  - b. 19
  - c. 91
  - d. 99
6. The most substantial difficulty in culturing prokaryotes in laboratory settings is related to \_\_\_\_\_.
  - a. the lack of knowledge about their needs for growth
  - b. growth requirements that are too difficult to meet
  - c. inefficient methods for resuscitation of viable but nonculturable (VBNC) organisms
  - d. the expense of techniques such as polymerase chain reaction (PCR)
7. Which of the following represents the earliest forms of life on Earth?
  - a. hydrothermal vent
  - b. microbial mat
  - c. meteorite
  - d. stromatolite
8. Which best summarizes the conditions of early Earth at the time that life first evolved?

- a. The atmosphere of early Earth was very different from today's atmosphere, but most other conditions (such as geologic upheaval and volcanic activity) were very much the same.
- b. The atmosphere of early Earth was very much like today's atmosphere, but many other conditions (such as geologic upheaval and volcanic activity) were very different.
- c. Early Earth had a very different atmosphere, was subject to extreme radiation, and had a lot of geologic upheaval and volcanic activity.
- d. Early Earth had a very different atmosphere and was subject to extreme radiation, but there was very little geologic upheaval or volcanic activity.
- 9.** Halophiles prefer conditions in which there is a \_\_\_\_\_.  
a. high sugar concentration  
b. salt concentration of at least 0.2 M  
c. pH of 3 or below  
d. high level of radiation
- 10.** The presence of a membrane-enclosed nucleus is a characteristic of \_\_\_\_\_.  
a. prokaryotic cells  
b. eukaryotic cells  
c. all cells  
d. viruses
- 11.** All prokaryotic and eukaryotic cells have four structures in common: the plasma membrane, the cytoplasm, nucleic acid, and \_\_\_\_\_.  
a. the cell wall  
b. ribosomes  
c. the nucleus  
d. organelles
- 12.** Which statement comparing the prokaryotes Bacteria and Archaea is false?  
a. The cytoplasm of both bacterial and archaean prokaryotic cells has a high concentration of dissolved solutes.  
b. Osmotic pressure in both types of prokaryotic cells is relatively high.  
c. The domains Bacteria and Archaea differ in the use of fatty acids versus phytanyl groups in their cell membranes.  
d. The domains Bacteria and Archaea have very similar cell wall structure.
- 13.** Pseudopeptidoglycan is a characteristic of the walls of some \_\_\_\_\_.  
a. eukaryotic cells  
b. bacterial prokaryotic cells  
c. archaean prokaryotic cells  
d. bacterial and archaean prokaryotic cells
- 14.** The cell wall, a feature of most prokaryotes, is \_\_\_\_\_.  
a. interior to the cell membrane  
b. exterior to the cell membrane  
c. a part of the cell membrane  
d. interior or exterior, depending on the particular cell
- 15.** Which statement summarizes what is known about macronutrient needs of prokaryotes?  
a. Boron is required in small amounts by some prokaryotic organisms.  
b. Manganese is required in small amounts by some prokaryotic organisms.  
c. Iron is required in small amounts by some prokaryotic organisms.  
d. Sulfur is needed in large amounts by prokaryotic organisms. It is part of the structure of some amino acids and is also present in some vitamins and coenzymes.
- 16.** Which statement about the importance of particular nutrients is false?  
a. Carbon is a macronutrient and major element in all macromolecules.  
b. Nitrogen is a macronutrient and necessary component of proteins and nucleic acids.  
c. Hydrogen is a macronutrient and key component of many organic compounds, including water.  
d. Iron is a macronutrient necessary for the function of cytochromes.
- 17.** What are prokaryotes that obtain their energy from chemical compounds called?  
a. phototrophs  
b. autotrophs  
c. chemotrophs  
d. heterotrophs
- 18.** What uses organic compounds as both an energy source and as a carbon source?  
a. chemolithotrophs  
b. photoautotrophs  
c. photoheterotrophs  
d. chemoorganotrophs
- 19.** A primary role of many prokaryotes in the carbon cycle is that of \_\_\_\_\_.  
a. decomposers  
b. primary producers  
c. primary consumers  
d. secondary consumers

- a. producers
  - b. decomposers
  - c. fixers
  - d. synthesizers
20. Ammonification is the process by which \_\_\_\_.
- a. ammonia is released during the decomposition of nitrogen-containing organic compounds
  - b. ammonium is converted to nitrite and nitrate in soils
  - c. nitrate from soil is transformed to gaseous nitrogen compounds
  - d. gaseous nitrogen is fixed to yield ammonia
21. Which is a macronutrient needed by prokaryotes?
- a. phosphorus
  - b. iron
  - c. chromium
  - d. boron
22. A disease that is constantly present in a population is called \_\_\_\_.
- a. pandemic
  - b. endemic
  - c. emerging
  - d. re-emerging
23. Which set of terms names diseases caused by bacteria?
- a. diphtheria, bubonic plague, yellow fever
  - b. yellow fever, dengue fever, bubonic plague
  - c. bubonic plague, diphtheria, cholera
  - d. cholera, diphtheria, dengue fever
24. Which of the following health issues is caused by biofilm colonization?
- a. dental plaque
  - b. dry scalp
  - c. skin rash
  - d. prosthetic discomfort
25. Which of the statements about the loci of biofilm-related disease is false?
- a. Biofilms are related to foodborne illnesses because they colonize food surfaces and food-processing equipment.
  - b. In healthcare environments, biofilms grow on ventilators, shunts, and other medical equipment.
  - c. Biofilms tend to colonize medical devices such as prostheses, contact lenses, and catheters.
  - d. Biofilms form in open wounds, burned tissue, or internal medical devices such as pacemakers.
26. Which best describes the crisis related to antibiotics?
- a. It is becoming too expensive to manufacture effective antibiotics.
  - b. It takes too much time to develop effective antibiotics; infections spread before treatment is available.
  - c. Bacteria are increasingly resistant to antibiotics used to treat and eradicate infections.
  - d. People are increasingly allergic to antibiotics commonly used in treatment.
27. Which statement about the cause of resistant bacteria is false?
- a. The excessive use of antibiotics has resulted in the natural selection of resistant forms of bacteria.
  - b. Antibiotics are used by patients with colds or the flu, the treatment for which antibiotics are useless.
  - c. There is excessive use of antibiotics in livestock and in animal feed.
  - d. Antibiotics are used by patients of different ages and the fact that their ages differ increases resistance.
28. Which statement about diseases is false?
- a. An epidemic is a disease that occurs in a high number of individuals in a population at a time.
  - b. A pandemic is a widespread, usually worldwide, epidemic.
  - c. An endemic disease is a disease that is constantly present, usually at high incidence, in a population.
  - d. An emerging disease is a disease that has appeared in a population for the first time.
29. Which statement best explains which organisms need nitrogen fixation and why?

- a. Prokaryotes cannot use gaseous nitrogen to synthesize macromolecules, so it must be converted into ammonia.
- b. Prokaryotes cannot use ammonia to synthesize macromolecules, so it must be converted into gaseous nitrogen.
- c. Eukaryotes cannot use ammonia to synthesize macromolecules, so it must be converted into gaseous nitrogen.
- d. Eukaryotes cannot use gaseous nitrogen to synthesize macromolecules, so it must be converted into ammonia.
- 30.** Which statement about nitrogen fixation is false?
- It can be accomplished abiotically, as a result of lightning.
  - It can be accomplished abiotically, as a result of industrial processes.
  - It can be accomplished biologically, by algae.
  - It can be accomplished biologically, by cyanobacteria.
- 31.** Which are three foods for which prokaryotes are used in their processing?
- cheese, yogurt, and milk
  - cheese, yogurt, and bread
  - wine, bread, and butter
  - milk, wine, and beer
- 32.** What was the initial benefit for humans in processing foods with prokaryotes?
- a. The foods taste better.
- b. Nutrients are preserved.
- c. The food is less stable.
- d. Nutrients were safer.
- 33.** Which best defines bioremediation?
- the use of microbial metabolism to clean up oil spills
  - the use of microbial metabolism to ferment food
  - the use of microbial metabolism to remove pollutants
  - the use of microbial metabolism to fix nitrogen
- 34.** Which statement about bioremediation is false?
- It includes removing agricultural chemicals.
  - It includes removing industrial by-products.
  - It includes cleaning up oil spills.
  - It includes cleaning up ammonia in soil.
- 35.** Nitrogen is an essential element that is widely available in the atmosphere. Because eukaryotes cannot use nitrogen in its gaseous form, they benefit from prokaryotes' conversion of gaseous nitrogen to \_\_\_\_.
- nitrates, a form of nitrogen they can use
  - phosphate, a different essential element they can use
  - ammonia, a form of nitrogen they can use
  - hydrogen, a different essential element they can use

## CRITICAL THINKING QUESTIONS

- 36.** Explain the relationship between Earth's ancient atmosphere and the evolution of some of the first life forms on Earth. Use the terms anaerobic and phototrophic, and explain the effect of cyanobacteria on the atmosphere.

- a. Phototrophic organisms appeared during the first two billion years of Earth's existence. Anaerobic organisms appeared within one billion years of Earth's formation. From these organisms evolved the cyanobacteria which produce oxygen as a by-product of photosynthesis, leading to the oxygenation of the atmosphere.
- b. For the first two billion years of Earth's existence, the atmosphere had no molecular oxygen. Thus, the first organisms were anaerobic. Cyanobacteria appeared within one billion years of Earth's formation. From these evolved the phototrophic organisms which produce oxygen as a by-product of photosynthesis, leading to the oxygenation of the atmosphere.
- c. For the first two billion years of Earth's existence, the atmosphere had no molecular oxygen. Thus, the first organisms were anaerobic. Phototrophic organisms appeared within one billion years of Earth's formation. From these organisms evolved the cyanobacteria, which produce oxygen as a by-product of photosynthesis, leading to the oxygenation of the atmosphere.
- d. For the first two billion years of Earth's existence, the atmosphere had no molecular oxygen. Thus, the first organisms were anaerobic. Cyanobacteria which produce oxygen as a by-product of photosynthesis, leading to the oxygenation of the atmosphere, appeared within one billion years of Earth's formation. From these organisms evolved phototrophic organisms.
- 37.** Extremophiles are considered an important area for research in the development of therapeutic drugs or industrial applications. Why do you think this is so?
- a. Extremophiles can be altered genetically in vitro to allow them to live in extreme conditions and this capability of alteration can be used to help humans. For example, some water-resistant prokaryotes have developed DNA repair mechanisms. Also, they could be developed and used in the treatment of human disease.
- b. Extremophiles have specialized adaptations that allow them to live in extreme conditions. These adaptations can be mobilized to help humans. For example, some water-resistant prokaryotes have developed DNA repair mechanisms. Also, they could be developed and used in the treatment of human disease.
- c. Extremophiles can be altered genetically in vitro to allow them to live in extreme conditions and this capability of alteration can be used to help humans. For example, some radiation-resistant prokaryotes have developed DNA repair mechanisms. Also, they could be developed and used in the treatment of human disease.
- d. Extremophiles have specialized adaptations that allow them to live in extreme conditions. These adaptations can be mobilized to help humans. For example, some radiation-resistant prokaryotes have developed DNA repair mechanisms. Also, they could be developed and used in the treatment of human disease.
- 38.** Describe briefly how you would detect the presence of a non culturable prokaryote in an environmental sample.
- a. Recombinant DNA techniques are used to detect the presence of a non-culturable prokaryote in an environmental sample. Polymerase chain reaction is used to amplify selected portions of prokaryotic DNA.
- b. Molecular biology techniques are used to detect the presence of a non-culturable prokaryote in an environmental sample. Electrophoresis is used to amplify selected portions of prokaryotic DNA.
- c. Molecular biology techniques are used to detect the presence of a non-culturable prokaryote in an environmental sample. Polymerase chain reaction is used to amplify selected portions of prokaryotic DNA.
- d. Recombinant DNA techniques are used to detect the presence of a non-culturable prokaryote in an environmental sample. Electrophoresis is used to amplify selected portions of prokaryotic DNA.
- 39.** Why do scientists believe that the first organisms on Earth were extremophiles?

- a. Earth's early environment was full of extreme places with much oxygen in the atmosphere, no ozone to shield Earth's surface from mutagenic radiation, much geologic upheaval and volcanic activity. Extremophiles are bacteria and archaea that are adapted to grow in extreme environments.
- b. Earth's early environment was full of extreme places with little oxygen in the atmosphere, no ozone to shield Earth's surface from mutagenic radiation, much geologic upheaval and volcanic activity. Extremophiles are bacteria and archaea that are adapted to grow in extreme environments.
- c. Earth's early environment was full of extreme places with little oxygen in the atmosphere, no ozone to shield Earth's surface from mutagenic radiation, less geologic upheaval and volcanic activity. Extremophiles are bacteria and archaea that are adapted to grow in extreme environments.
- d. For the first two billion years of Earth's existence, the atmosphere had no molecular oxygen.

**40. Describe a typical prokaryotic cell.**

- a. It has a cell wall enclosing cell membrane, cytoplasm, ribosomes and nucleoid region with genetic material. It may have a protective capsule, flagellum, pili and plasmids.
- b. It has a cell wall enclosing cell membrane, cytoplasm, ribosomes and nucleus containing genetic material. It may have a protective capsule, flagellum, pili and plasmids.
- c. It has a cell wall enclosing nuclear membrane, cytoplasm, ribosomes and nucleoid region with genetic material. It may have a protective capsule, flagellum, pili and plasmids.
- d. It has a cell wall enclosing nuclear membrane, cytoplasm, mitochondria, vacuoles and nucleoid region with genetic material. It may have a protective capsule, flagellum, pili and plasmids.

**41. Explain the statement that both Archaea and Bacteria have the same basic structures, but these structures are built from different chemical components.**

- a. Typical cells in Archaea and Bacteria contain a cell wall, cell membrane, nucleoid region, ribosomes, and often a capsule, flagellum, and pili. However, these are sometimes made from different chemical compounds. Cell walls of Bacteria contain peptidoglycan while Archaea do not. Plasma membrane lipids of Bacteria are fatty acids while those of Archaea are phytanyl groups.
- b. Typical cells in Archaea and Bacteria contain a cell wall, cell membrane, nucleoid region and often a capsule, flagellum, and pili but in some instances different chemical compounds make them. Cell walls of Bacteria contain peptidoglycan while Archaea do not. Bacteria contain 70S ribosomes while Archaea contain 80S ribosomes.
- c. Typical cells in Archaea and Bacteria contain a cell wall, nuclear membranes, nucleoid region and often a capsule, flagellum, and pili but in some instances different chemical compounds make them. Cell walls of Bacteria contain peptidoglycan while Archaea do not. Plasma membrane lipids of bacteria are fatty acids, while the plasma membrane lipids of Archaea are phytanyl groups.
- d. Typical cells in Archaea and Bacteria contain a cell wall, cell membrane, nucleoid region and often a capsule, flagellum, and pili but in some instances different chemical compounds make them. Cell walls of Bacteria contain peptidoglycan while Archaea do not. Plasma membrane lipids of Bacteria are phytanyl groups, while the plasma membrane lipids of Archaea are fatty acids.

**42. Three basic prokaryotic categories are cocci, spirilli, and bacilli. Describe the basic structural features of each category.**

- a. These three prokaryote groups have similar basic structural features. They typically have cell walls enclosing nuclear membranes, cytoplasm, ribosomes, mitochondria and nucleoid region with genetic material. They may have a protective capsule, flagellum, pili and plasmids.
- b. Coccii and spirilli have similar basic structural features. They typically have cell walls enclosing cell membranes, a flagellum for locomotion and pili for attachment. Bacilli are rod shaped which contain ribosomes and a nucleoid region with genetic material.
- c. These three prokaryote groups have similar basic structural features. They typically have cell walls enclosing cell membranes, cytoplasm, ribosomes and a nucleoid region with chromosomes. They may have a protective capsule, flagellum, pili and plasmids.
- d. Bacilli and spirilli have similar basic structural features. They typically have cell walls enclosing nuclear membranes, a flagellum for locomotion and pili for attachment. Coccii are spherical containing ribosomes and a nucleoid region with genetic material.

**43.** Which macronutrient do you think is most important? What evidence can you offer to support your choice?

- a. Carbon because it represents 12 percent of the total dry weight of a typical cell and is a component of all macromolecules.
- b. Oxygen because it is necessary and is a major component for all macromolecules. It also accounts for 50% of the total composition of a cell.
- c. Carbon because it is necessary and is a major component for all macromolecules. It also accounts for 50% of the total composition of a cell.
- d. Nitrogen because it is necessary and is a major component for all macromolecules. It also accounts for 50% of the total composition of a cell.

**44.** A bacterium requires only a particular amino acid as an organic nutrient and lives in a completely lightless environment. What mode of nutrition (free energy and carbon) does it use? Justify your response.

- a. Chemoheterotroph, as it must rely on chemical sources of energy living in a lightless environment and a heterotroph if it uses organic compounds for its carbon source.
- b. Chemoorganotroph, as it must rely on chemical sources of energy living in a lightless environment and an organotroph if it uses organic compounds other than carbon dioxide for its carbon source.
- c. Chemolithoautotroph, as it must rely on chemical sources of energy living in a lightless environment and an autotroph if it uses organic compounds other than carbon dioxide for its carbon source.
- d. Chemoheterotroph, as it must rely on chemical sources of energy living in a lightless environment and a heterotroph if it uses organic compounds other than carbon dioxide for its carbon source.

**45.** Assuming that you could synthesize all of the nitrogen-containing compounds needed if you had nitrogen, what might you eat for a typical meal if you could fix nitrogen like some prokaryotes?

- a. My meal might be fruits or vegetables and water as nitrogen is present in the highest amount in water.
- b. My meal might be fruits or vegetables, water and air as atmospheric nitrogen could be simply absorbed.
- c. My meal might be fruits or vegetables, cheese, meat, water, and air as atmospheric nitrogen could be simply absorbed.
- d. My meal might be cheese or meat, water, and air as atmospheric nitrogen could be simply absorbed.

**46.** Which are more important: macronutrients or micronutrients? Explain your reasoning.

- a. Neither are important, as cells can survive as well as carry out essential functions without both types of nutrients.
- b. Micronutrients, even though they are required in lesser amounts, without them cells cannot survive and carry out functional processes.
- c. Macronutrients, as they are required in larger amounts by cells and thus are more essential than micronutrients.
- d. Neither is more important as both types of nutrients are absolutely necessary for prokaryotic cell structure and function.

**47.** Identify and discuss a bacterial disease that caused a historically important plague or epidemic. What is the modern distribution of this disease?

- a. Bubonic plague caused by *Yersinia pestis* was a pandemic that occurred in the 14th century. In modern times, there are only about 100 cases of bubonic plague each year. The bacterium responds well to modern antibiotics.
- b. Bubonic plague caused by *Yersinia enterocolitica* was a pandemic that occurred in the 14th century. In modern times, there are about 1,000 to 3,000 cases of bubonic plague each year. The bacterium responds well to modern antibiotics.
- c. Pneumonic plague caused by *Yersinia pestis* was a pandemic that occurred in the 14th century. In modern times, there are about 1,000 to 3,000 cases of pneumonic plague each year. The bacterium responds well to modern antibiotics.
- d. Bubonic plague caused by *Yersinia pestis* was a pandemic that occurred in the 14th century. In modern times, there are about 1,000 to 3,000 cases of bubonic plague each year. The bacterium responds well to modern antibiotics.

**48.** Have foodborne illnesses related to biofilms changed over time? Explain.

- a. Yes, better sterilization and canning procedures have reduced the incidence of botulism. Most cases of foodborne illness now are related to small-scale food production.
- b. No, better sterilization and canning procedures have reduced the incidence of botulism. Most cases of foodborne illness now are related to small-scale food production.
- c. No, better sterilization and canning procedures have increased the incidence of botulism. Most cases of foodborne illnesses now are related to large-scale food production.
- d. Yes, better sterilization and canning procedures have reduced the incidence of botulism. Most cases of foodborne illnesses now are related to large-scale food production.

**49.** What is the relationship between MRSA and the problem of antibiotic resistance?

- a. Indiscriminate use of antibiotics results in the population growth of resistant bacteria like MRSA.
- b. Infrequent use of antibiotics results in the population growth of resistant bacteria like MRSA.
- c. Indiscriminate use of antibiotics results in the population decline of resistant bacteria like MRSA.
- d. Infrequent use of antibiotics results in the population stability of resistant bacteria like MRSA.

**50.** What was the Plague of Athens? What is the modern distribution of this disease?

- a. The Plague of Athens was a disease caused by *Yersinia pestis* that killed one-quarter of Athenian troops in 430 BC. Between 10 and 15 million cases of typhoid fever occur today, resulting in over 10,000 deaths annually.
- b. The Plague of Athens was a disease caused by *Salmonella entericaserovar typhi* that killed one-quarter of Athenian troops in 430 BC. Between 5 and 10 million cases of typhoid fever occur today, resulting in over 20,000 deaths annually.
- c. The Plague of Athens was a disease caused by *Yersinia pestis* that killed one-quarter of Athenian troops in 430 BC. Between 16 and 33 million cases of typhoid fever occur today, resulting in over 200,000 deaths annually.
- d. The Plague of Athens was a disease caused by *Salmonella entericaserovar typhi* that killed one-quarter of Athenian troops in 430 BC. Between 16 and 33 million cases of typhoid fever occur today, resulting in over 200,000 deaths annually.

**51.** Identify three beneficial results of symbiotic nitrogen fixation.

- a. Plants benefit from an endless supply of nitrogen; soils benefit from being naturally fertilized; and bacteria benefit from using potassium from plants.
- b. Plants benefit from a limited supply of nitrogen; soils benefit from being naturally fertilized, and bacteria benefit from using photosynthates from plants.
- c. Plants benefit from an endless supply of carbon; soils benefit from being naturally fertilized; and bacteria benefit from using photosynthates from plants.
- d. Plants benefit from an endless supply of nitrogen; soils benefit from being naturally fertilized; and bacteria benefit from using photosynthates from plants.

**52.** Why is the processing of foods with prokaryotes considered an example of early biotechnology?

- a. Prokaryotes have been used to only make specific food products like cheese, wine, bread, beer and yogurt since before the term biotechnology was coined.
- b. Prokaryotes have been used to make and alter specific food products like cheese, wine, single cell proteins, beer and yogurt since before the term biotechnology was coined.
- c. As prokaryotes have been used to make and alter specific food products like cheese, wine, bread, beer and yogurt since before the term biotechnology was coined.
- d. As prokaryotes have been used to alter specific food products like cheese, wine, bread, beer and yogurt since before the term biotechnology was coined.

**53.** On what does the success of bioremediation of oil spills depend?

- a. Success depends on the presence of only aromatic and highly branched hydrocarbon chain compounds and the temperature.
- b. Success depends on the presence of less nonvolatile and more aromatic and highly branched hydrocarbon chain compounds and the temperature.
- c. Success depends on the type of oil compounds, the presence of naturally-occurring oil-solubilizing prokaryotes in the ocean, and the type of water body.
- d. Success depends on the type of oil compounds, the presence of naturally-occurring oil-solubilizing prokaryotes in the ocean and the temperature.

## TEST PREP FOR AP® COURSES

**55.** Which of the following pieces of evidence is the BEST support for the alternative scenario of early life formation, in which organic compounds on early Earth formed near submerged volcanoes?

- a. Some prokaryotes that live near deep-sea vents today use hydrogen as an energy source.
- b. Fossilized stromatolites that are 3.5 billion years old are found near deep-sea vents.
- c. Extremophiles that exist today live in a variety of extreme environments, including those that are high in salinity.
- d. The chemical composition of water around deep-sea vents is the same as it was on early Earth.

**56.** Stanley Miller and Harold Urey conducted experiments which demonstrated that several organic compounds could be formed spontaneously by simulating the conditions of Earth's early atmosphere. When Miller

**54.** Why is the relationship between sustainable agriculture and nitrogen fixers called a mutualism?

- a. Due to agrobacterium which are nitrogen fixers, plants benefit from an endless supply of nitrogen; soils benefit from being naturally fertilized and bacteria benefit from using photosynthates from plants.
- b. Due to rhizobia, which are nitrogen fixers, plants benefit from an endless supply of nitrogen; soils benefit from being naturally fertilized and bacteria benefit from using photosynthates from plants.
- c. Due to rhizobia, which are nitrogen fixers, plants benefit from an endless supply of nitrogen; soils benefit from being naturally fertilized and bacteria benefit from using potassium from plants.
- d. Due to rhizobia, which are nitrogen fixers, plants benefit from a limited supply of nitrogen; soils benefit from being naturally fertilized and bacteria benefit from using potassium from plants.

and Urey repeated their experiment without the electrical discharge, no organic compounds were found. Hypothesize what might explain this result. Consider your answer in the context of the conditions of early Earth.

- a. The lack of organic compounds without the sparks indicates that organic components are formed from biotic components.
- b. The first trial of the experiment must have been done incorrectly.
- c. Abiotic molecules can only develop into organic molecules in the presence of oxygen, so oxygen should be added.
- d. Lightning, or some form of energy, is needed for the inorganic molecules in the atmosphere to interact with each other. This indicates that a similar energy source was present on early Earth which stimulates the interaction and development.

**57.** Laboratory experiments have demonstrated that the abiotic synthesis of organic molecules in condition similar to those of early Earth is possible. Which of the following provides additional support for the idea of abiotic synthesis of organic compounds?

- a. Analysis of the chemical composition of meteorites sometimes yields amino acids.
- b. A hydrothermal vent in the Sea of Cortés releases hydrogen sulfide and iron sulfide.
- c. Researchers have dripped solutions of amino acids onto hot surfaces to produce amino acid polymers.
- d. Some present-day prokaryotes live and reproduce in very extreme and unforgiving environments, such as the Arctic.

**58.** Which of the following cell types does **Figure 22.10** illustrate?

- a. Plant cell
- b. Animal cell
- c. Bacterial cell
- d. Fungal cell

**59.** Which option best describes the function and presence of cell organelles among prokaryotes and eukaryotes?

- a. Ribosomes are the sites of protein synthesis found in prokaryotic and eukaryotic cells. Cell wall is a protective layer, typical in prokaryotic cells and in some eukaryotes. Chromosomal DNA, the genetic material of the cell is present in a nucleoid region in prokaryotes while enclosed in a nucleus in eukaryotes.
- b. Ribosomes are the sites of protein synthesis found in prokaryotic and eukaryotic cells. The cell wall is a protective layer found in some prokaryotic and eukaryotic cells. Chromosomal DNA is the genetic material of the cell present in a nucleoid region in prokaryotes while in eukaryotes, it is enclosed in a nucleus.
- c. Ribosomes are sites of ATP production found in both prokaryotic and eukaryotic cells. The cell wall is a protective layer, typically found in prokaryotic cells and in some eukaryotes. Chromosomal DNA is present in a nucleoid region while enclosed in a nucleus in eukaryotes. It is the genetic material of the cell.
- d. Ribosomes are the sites of protein synthesis found in prokaryotic and eukaryotic cells. The cell wall is a protective layer, typically found in prokaryotic cells and in some eukaryotes. Chromosomal DNA, the genetic material of the cell is present in a nucleus in prokaryotes while it is enclosed in a nucleoid region in eukaryotes.

**60.** A nonpathogenic bacterium acquires resistance to antibiotics. Which of the following scenarios describing

how this strain could pose a health risk to people is false?

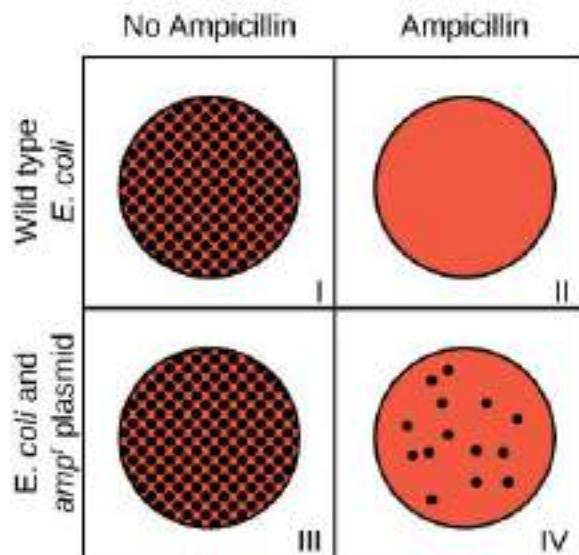

- a. Genes for antibiotic resistance are transferred from the nonpathogenic bacterium to a pathogenic bacterium via transduction.
- b. Genes for antibiotic resistance are transferred from the nonpathogenic bacterium to a pathogenic bacterium via transformation.
- c. Genes for antibiotic resistance are transferred from the nonpathogenic bacterium to a pathogenic bacterium via conjugation.
- d. Genes for antibiotic resistance are transferred from the nonpathogenic bacterium to a pathogenic bacterium via binary fission.

**61.** In a rapidly changing environment, which prokaryotic population would you hypothesize likely to be more successful: one that included individuals capable of conjugation or one that did not?

- a. A population including individuals capable of conjugation would be more successful because all of its members would form recombinant cells having new gene combinations advantageous in a new environment.
- b. A population including individuals capable of conjugation would be more successful as some members could form recombinant cells having new gene combinations advantageous in a new environment.
- c. A population including individuals not capable of conjugation would be more successful as the members undergoing conjugation would form new recombinant cells having gene combinations lethal in the new environment.
- d. A population including individuals not capable of conjugation would be more successful because conjugation will result in an increase in genetic diversity of the prokaryotic population which will be disadvantageous in a new population.

**62.** Plates that have only ampicillin-resistant bacteria growing include which of the following?

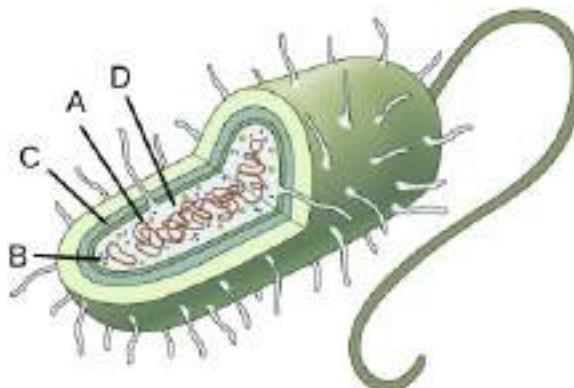

### Nutrient Agar Plates

63. Given your understanding of the experiment and of bacterial genetic recombination, explain why there are fewer colonies on plate IV than on plate III.
- a. I only  
b. III only  
c. IV only  
d. I and II

- a. All *E. coli* cells were not successfully transformed on plate IV.
- b. The nutrient agar medium inhibited the growth of some bacteria on plate IV.
- c. All *E. coli* cells were successfully transformed on plate IV.
- d. The bacteria in plate III were naturally resistant to ampicillin.

64. Which of the labeled structures in the diagram allows you to positively identify the cell as a prokaryote?

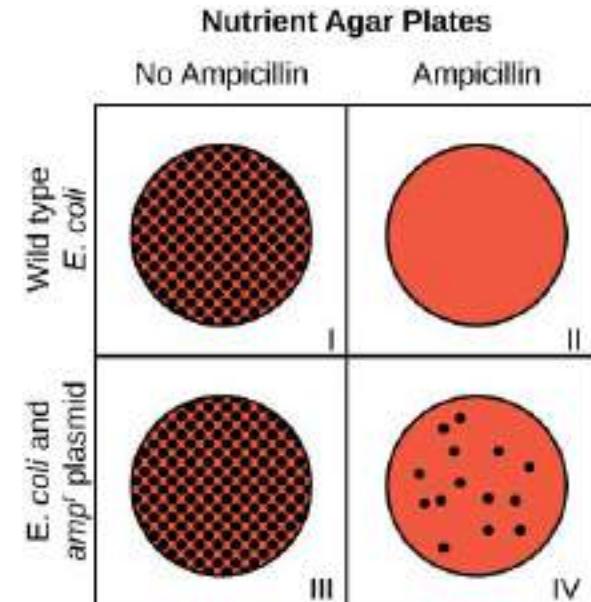

- a. A, circular DNA
- b. B, ribosome
- c. C, cell wall
- d. D, cytoplasm

65. A bacterial species that is a methanogen is discovered. If you wanted to build on this discovery to better understand the evolution of mechanisms related to the ability to capture, store, and use free energy in prokaryotes, which question would you pose to answer?

- a. Have metabolic pathways evolved separately in Bacteria and Archaea?
- b. Should all methanogens be classed as Archaea in evolutionary phylogeny?
- c. Have methanogens evolved to live in both moderate and extreme environments?
- d. Did the methanogenic bacteria species also evolve as a strict anaerobe?

66. What is another question you might pose to learn more about the structural features that allow for the capture, storage, and use of free energy by archaean methanogens?

- a. Do archaean methanogens differ from other Archaea structurally, and if so, in what way? Is one or more of these structural differences related to these methanogens' ability to use H<sub>2</sub> to oxidize CO<sub>2</sub>?
- b. Do archaean methanogens differ from other Bacteria structurally, and if so, in what way? Is one or more of these structural differences related to these methanogens' ability to use CO<sub>2</sub> to oxidize H<sub>2</sub>?
- c. Do archaean methanogens differ from other Archaea structurally, and if so, in what way? Is one or more of these structural differences related to these methanogens' ability to use CO<sub>2</sub> to oxidize H<sub>2</sub>?
- d. Do archaean methanogens differ from other Archaea structurally, and if so, in what way? Is one or more of these structural differences related to these methanogens' ability to use H<sub>2</sub>O to oxidize H<sub>2</sub>?
- 67.** Which set of phrases related to nutritional and metabolic adaptations best fits the organisms described?
- chemoautotrophs, obligate anaerobes
  - chemoautotrophs, facultative anaerobes
  - chemoheterotrophs, facultative anaerobes
  - chemoheterotrophs, obligate anaerobes
- 68.** In an experiment, researchers grew plant seedlings in soils to which one of two strains of bacteria were added. A control group had no bacteria added to the soil. The seedlings' uptake of the nutrient potassium increased dramatically in the soil with Strain 1 and decreased dramatically in the soil with Strain 2. What specific and broad inferences about the relationship between the bacteria, the seedlings, and available nutrients can you make?
- a. The Strain 2 bacteria increased the availability of potassium in the soil and this nutrient was needed and used by the seedlings in the soil. The Strain 1 bacteria decreased the availability of potassium in the soil.
- b. The soil with Strain 1 bacteria must have had more potassium in comparison to soil with Strain 2 bacteria. The seedlings took up more potassium in Soil 1 than in 2 due to this.
- c. The Strain 1 bacteria increased the availability of potassium in the soil and this nutrient was needed and used by the seedlings in the soil. The Strain 2 bacteria decreased the availability of potassium in the soil.
- d. The Strain 1 bacteria decreased the availability of potassium in the soil and this nutrient was needed and used by the seedlings in the soil. The Strain 2 bacteria increased the availability of potassium in the soil.
- 69.** In a hypothetical research situation, scientists discover bacterial endospores in silt at the bottom of a marsh that has been contaminated with a pollutant for 25 years. The silt of the marsh was deposited in annual layers. The age of the endospores can be estimated, then, by identifying the layer of silt in which the endospores are found. In flask A, researchers place 20-year-old endospores along with growth medium and the pollutant. In flask B, researchers place 100-year-old endospores along with growth medium and the pollutant. Which statement describes the results you would expect to see in the growth of the flasks?
- The growth in flask A will exceed that of flask B.
  - The growth in flask B will exceed that of flask A.
  - The growth each flask will be about equal.
  - There will be little to no growth in each flask.
- 70.** In a hypothetical research situation, scientists discover bacterial endospores in silt at the bottom of a marsh that has been contaminated with a pollutant for 25 years. The silt of the marsh was deposited in annual layers. The age of the endospores can be estimated, then, by identifying the layer of silt in which the endospores are found. In flask A, researchers place 20-year-old endospores along with growth medium and the pollutant. In flask B, researchers place 100-year-old endospores along with growth medium and the pollutant. Explain why you would expect to see more growth in one particular flask than in the other.

- a. Because endospores formed 20 years ago would be more dormant compared to endospores formed 100 years ago, before the marsh was polluted.
- b. Because endospores formed 20 years ago would be less adapted to polluted conditions compared to endospores formed 100 years ago, before the marsh was polluted.
- c. Because endospores formed 20 years ago would be more adapted to polluted conditions compared to endospores formed 100 years ago, before the marsh was polluted.
- d. Because endospores formed 20 years ago would be less dormant compared to endospores formed 100 years ago, before the marsh was polluted.

**71.** In a hypothetical research situation, scientists discover bacterial endospores in silt at the bottom of a marsh that has been contaminated with a pollutant for 25 years. The silt of the marsh was deposited in annual layers. The age of the endospores can be estimated, then, by identifying the layer of silt in which the endospores are found. In flask A, researchers place 20-year-old endospores along with growth medium and the pollutant. In flask B, researchers place 100-year-old endospores along with growth medium and the pollutant. Suppose the researchers observe the flasks for a while, continuing to replenish growth medium and pollutant as necessary. Which statement describes the results you would expect to see in the growth of the flasks after some time?

- a. The growth in flask A will continue to exceed that of flask B.
- b. The growth in flask B will exceed continue to exceed that of flask A.
- c. Eventually, the difference in the growth in each flask will lessen.
- d. Eventually, will be little to no growth in each flask.

**72.** In a hypothetical research situation, scientists discover bacterial endospores in silt at the bottom of a marsh that has been contaminated with a pollutant for 25 years. The silt of the marsh was deposited in annual layers. The age of the endospores can be estimated, then, by identifying the layer of silt in which the endospores are found. In flask A, researchers place 20-year-old endospores along with growth medium and the pollutant. In flask B, researchers place 100-year-old endospores along with growth medium and the pollutant. Suppose the researchers observe the flasks for a while, continuing to replenish growth medium and pollutant as necessary. If the difference in the growth in each flask lessened after some time, which statement explains why?

- a. Because the endospores formed 100 years ago, before the marsh was polluted, they would evolve resistance to the pollutant fairly quickly. The bacteria in flask B would then grow more prolifically, and the difference in population size of each flask would lessen.
- b. Because the endospores formed 20 years ago would lose their resistance to the pollutant. The bacteria in flask A would die, and the difference in population size of each flask would lessen.
- c. Because the endospores formed 100 years ago, before the marsh was polluted, they would lose their resistance to the pollutant. The bacteria in flask B would then grow more prolifically, and the difference in population size of each flask would lessen.
- d. Because the endospores formed 20 years ago would evolve resistance to the pollutant fairly quickly. The bacteria in flask A would die, and the difference in population size of each flask would lessen.

**73.** How does resistance spread in bacteria?

- a. By undergoing genetic recombination through conjugation, transduction, and transformation.
- b. By undergoing reproduction through binary fission.
- c. By undergoing genetic recombination through conjugation and transformation only.
- d. Reproduction among bacteria through any mechanism results in the spread of antibiotic resistance genes.

**74.** Health officials worldwide are concerned about antibiotic resistance in bacteria that cause disease. In patients infected with nonresistant strains of the bacterium that causes tuberculosis, antibiotics can relieve symptoms fast—in as short of a time as a few weeks. However, it takes much longer to stop infection entirely, and patients may discontinue treatment once symptoms are abated. In a hypothetical study, researchers found a much higher incidence of recurrent tuberculosis infection in patients who discontinued treatment once symptoms were relieved, but before the planned course of treatment was complete. Which statement best explains this result?

- a. The wrong course of antibiotics was used on the patient, so the infection was never treated.
- b. Not all of the bacteria were killed, and the remaining ones reproduced and bring back the symptoms of infection.
- c. The antibiotics were not prescribed for a long enough time to treat the infection.
- d. The infection was actually viral in nature, and so the antibiotics were a useless treatment.

**75.** Human intestines are home to hundreds of species of

bacteria. One of these, *Bacteroides thetaiotaomicron*, has the capability of digesting complex plant materials that human enzymes cannot digest. Its presence in the human guts makes a significant contribution to human metabolic processes. Which term best describes the relationship between humans and *B. thetaiotaomicron*?

- a. commensalistic
- b. mutualistic
- c. parasitic
- d. pathogenic

**76.** If you suddenly and dramatically changed your diet, how might this affect the diversity of prokaryotic species that live in your intestine?

- a. The diversity would not get altered and would remain the same.
- b. Species abundance and relative distribution may increase.
- c. Species abundance and relative distribution may get affected.
- d. Species abundance and relative distribution may decrease.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**78.** That the uniformity of cell size in prokaryotes is independent of the conditions of cell growth has long been a puzzle. Suppose that cells grew for a random period of time and then divided. The largest and smallest, by sometimes dividing to make even larger or smaller cells, would be expected to broaden the distribution of cell sizes, as shown in the diagram on the left for a time,  $t_2$ , after a time  $t_1$ . Competing claims are made to explain the fact, however, that the distribution does not broaden: 1) There is a “timer” that initiates cell division, and 2) there is a volume threshold that, when reached, initiates cell division. Recently (Amir, *Phys. Rev. Lett.*, 2014), a third model was suggested: From the end of the last cell division to the next, the cell volume increases by a constant value.

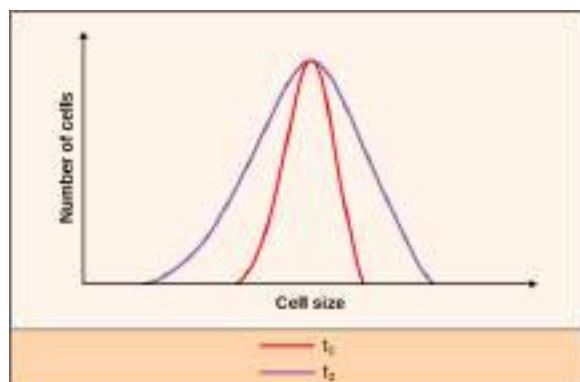

Figure 22.30

**77.** More than 100 bacterial species live on the surface of the human body. Bacteria cover portions of human skin in concentrations of up to 8 million cells per square centimeter. In particular, human sebaceous glands support the growth of the bacterium *Propionibacterium acnes*, which uses oil from the glands for food. Two strains of *P. acnes* are associated with the development of acne on human skin, but other strains are associated with healthy skin. Which statement best describes the relationship between humans and *P. acnes*?

- a. In some cases it is commensal and in others it is parasitic.
- b. In some cases it is mutualistic and in others it is commensalistic.
- c. It is almost always parasitic.
- d. It is almost always mutualistic.

**A. Justify the claim** of the third model by i) rejecting the two alternative claims, using the fact that growth rate depends on the availability of resources and considering that regulation of expression at a critical volume would require measurement of total volume by the cell, and ii) arguing that adding a constant volume before each cell division would narrow the cell size distribution.

**B. Design a plan** to test both the most recent model and the timer model.

**79.** Gram-negative bacteria have an inner cytoplasmic membrane separated by a peptidoglycan layer from a second outer membrane. In addition, transport proteins called efflux pumps span this double membrane and actively eliminate chemicals such as antibiotics that pass through porins on the outer membrane. These efflux pumps can confer multi-drug resistance, a situation that is threatening human health.

**A. Explain** how combining a drug that disrupts ATP synthesis in bacteria with antibiotics is a possible strategy for the treatment of bacterial infections caused by antibiotic-resistant gram-negative bacteria.

ATP synthesis in prokaryotes is accomplished by a protein that connects the extracellular space to the cytoplasm. In gram-negative bacteria, the proton gradient that supplies the free energy to convert ADP into ATP is established across the inner membrane.

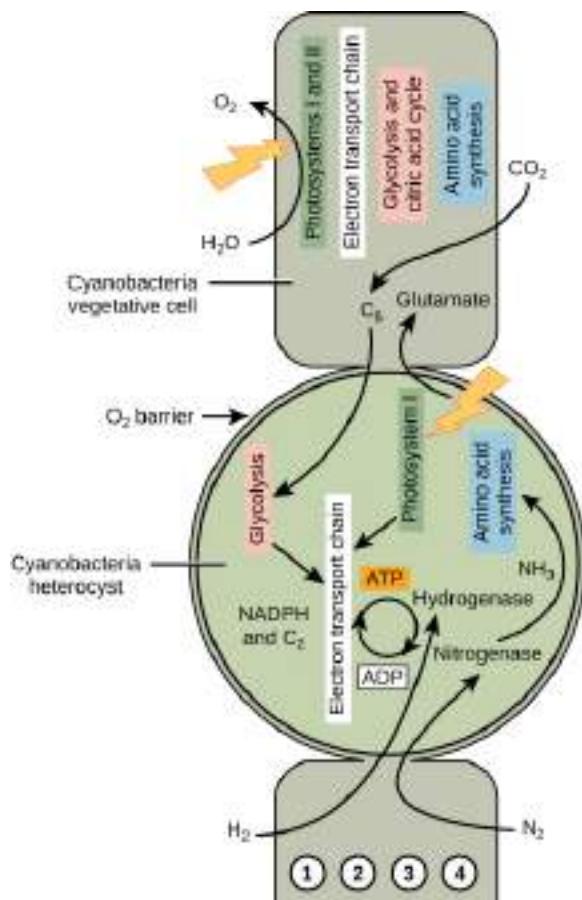

**B. Predict** differences in the interactions of eukaryotic and prokaryotic cells with a drug molecule that successfully targets ATP synthesis and provide reasoning for your

predictions.

In gram-positive bacteria, ATP synthesis is accomplished by a protein that spans the single membrane and the outer cell wall. During the production of yogurt and wine, which rely on gram-positive bacteria, the pH is controlled. Sodium bicarbonate secretions from the pancreas maintain the pH of the human intestine, where many beneficial methanogens are gram-positive bacteria.

**C. Explain** why homeostasis for gram-positive bacteria requires control of extracellular pH.

**80.** Cyanobacteria are single-celled organisms with the capacity to fix nitrogen,  $N_2$ . Some cyanobacteria cooperatively aggregate as filaments, and heterocysts may form at intervals along the filament between a pair of vegetative (actively growing) cells. Heterocysts are specialized cells that express certain genes when nitrogen becomes limiting. The nitrogenase complex converts the nitrogen in  $N_2$  into  $NH_3$  (ammonia). This enzyme functions only under anaerobic conditions that are, in part, enforced by an  $O_2$  barrier surrounding the cytoplasm of the heterocyst, as shown below.

**Figure 22.31**

A. Other modifications displayed in the diagram maintain an anaerobic state and synthesize ammonia from  $N_2$ . Identify four modifications of vegetative cells, either by their addition to or omission from the heterocyst. **Refine**

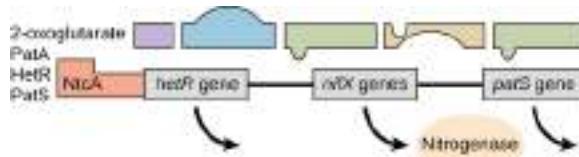

**the representation** by drawing a line between each of the three numbered circles and the feature.

B. Further **refine the representation** by providing a brief description of the role of each modification in either regulating oxygen or synthesizing ammonia.

The Krebs cycle in prokaryotes and eukaryotes differs. In prokaryotes, the Krebs cycle occurs in the cytoplasm and the intermediate 2-oxoglutarate (?-ketoglutarate) is absent.

C. **Construct a representation** of the regulation of genes encoding the nitrogen fixation system using the elements below. The irregular shapes are either metabolites or transcription factors, NtcA, HetR, and PatS. In your representation, label each shape using the names on the left in the figure below. Your representation must account for these observations:

- when nitrogen is limiting, 2-oxoglutarate concentration in the cytoplasm increases
- HetR is transcribed when 2-oxoglutarate concentrations are low
- PatS is transcribed when 2-oxoglutarate concentrations are low
- nitrogenase is transcribed when HetR concentrations are high and PatS concentrations are low
- when PatS concentrations are high, nifX genes are not transcribed

**Figure 22.32**

D. Heterocysts form along the filament separated by a fixed number of vegetative cells. Based on your model of the regulation of heterocyst development, **make and support a claim** that accounts for this pattern.

**81.** *Escherichia coli* Strain A is able to grow in a minimal medium only when supplemented with methionine and biotin. Strain B is able to grow in a minimal medium only when supplemented with threonine, leucine, and thiamine. The two strains are incubated together in a medium containing each supplement. They are then transferred to a minimal medium with no supplements, and each strain is able to grow under these conditions.

A. **Describe** the evidence that supports information exchange between Strain A and Strain B, and the mechanisms that can account for this behavior demonstrated by Lederberg and Tatum (*Nature*, 1946).

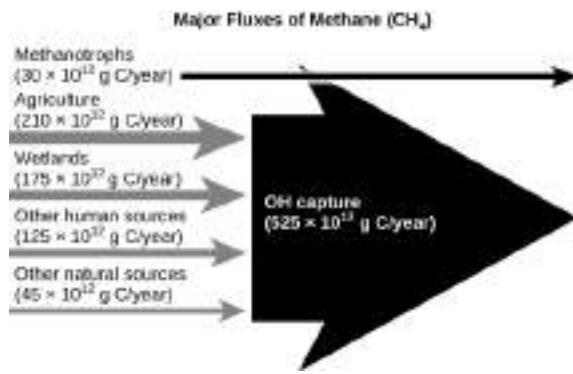

Colistin is regarded as a last-resort antibiotic in the treatment of multi-drug-resistant, gram-negative bacteria. The MCR-1 gene that confers colistin resistance was recently detected in a plasmid found in *E. coli* from the

intestines of human patients (Liu et al., *Lancet Infect. Dis.*, 2016). Colistin is cheap to produce, is often used as a feed supplement for domesticated animals (12,000 metric tons per year in 2015), and its use is increasing. Colistin is also unstable in water (Healan et al., *Antimicrob. Agents Chemother.*, 2012).

**B. Describe** the possible biological consequences of an immediate ban on the use of colistin in agriculture.

**82.** Life on Earth is sustained by four processes that are unique to prokaryotes: 1) methanogens reduce hydrogen or carbon atoms to produce methane; 2) methanotrophs combine methane with oxygen to form formaldehyde; 3) nitrogen fixation converts N<sub>2</sub> into ammonia; and 4) nitrification converts ammonia into nitrates. These processes recycle matter, maintaining the carbon (1 and 2) and nitrogen (3 and 4) cycles.

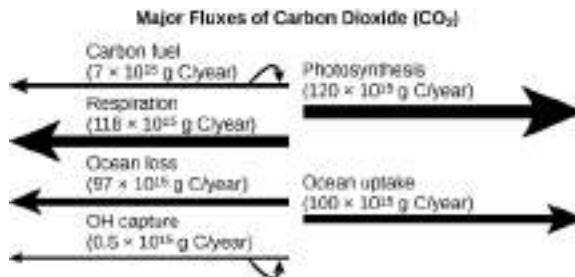

Methanogens are strictly anaerobic. Estimates of global fluxes of methane from major sources (Kirschke, *Nature Geoscience*, 2013, in units of 10<sup>12</sup> g C/year) are shown in the figure below. Agricultural sources are predominately the microbiomes of ruminants (cows, goats, etc.) and rice cultivated in shallow ponds where anoxic compost and crop residues promote methanogen growth on roots. Other major human activities that contribute to atmospheric methane levels are landfills and natural gas drilling.

**Figure 22.33**

The fate of this methane is also shown. Most reacts with OH in the lower atmosphere to make formic acid, which then decomposes into carbon dioxide and water. Methanotrophs consume the remaining methane.

Methane is a component of the carbon cycle, but it is much less significant than carbon dioxide, whose major fluxes are shown in units of 10<sup>15</sup> g C/year (NASA, 2015). Oceanic uptake and loss of CO<sub>2</sub> are primarily abiotic. Prokaryotic marine organisms account for approximately 50% of the biotic exchanges.

**Figure 22.34**

**A. Compare** quantitatively the rates of carbon cycling as methane between the biosphere and atmosphere.

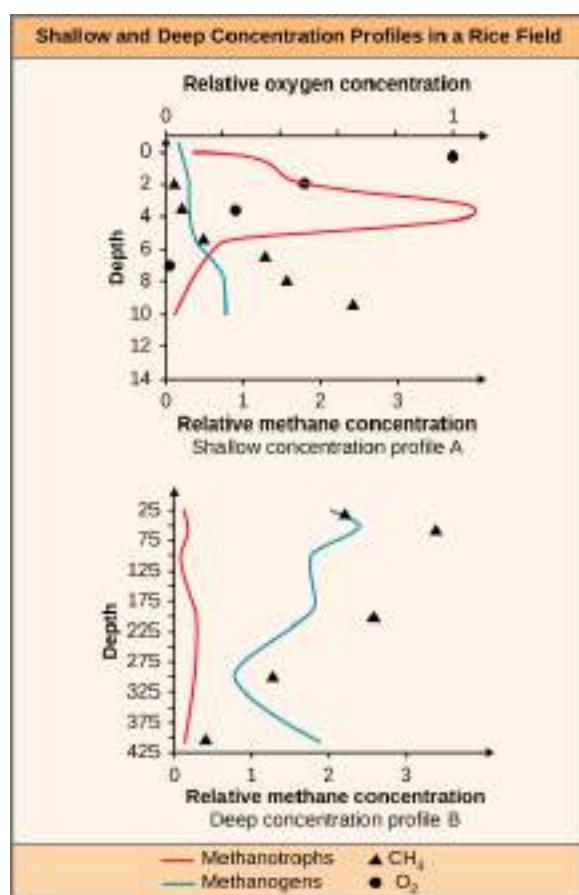

**Calculate** the percentage of methane production that is anthropocentric (due to human actions).

**B.** Assuming that the rates of carbon dioxide exchange shown in the diagram are accurate, **analyze** these data to **identify** a missing contribution to the carbon budget.

Recently, it was discovered that ruminants fed nitrooxypropanoic acid reduced their methane release from digestion by approximately 50% and increased the rate of meat production by as much as 80% (E. Duin et al., *Proc. Natl. Acad. Sci.*, 2016).

**C.** Since methane is a greenhouse gas, its release into the atmosphere further increases global temperatures. It has been claimed that a feed supplement program will reduce the effects of climate change. **Predict** the consequences of such a program and provide reasoning for your prediction.

A vertical profile of methane and oxygen below the surface of a rice paddy are shown in the graph below (Lee et al., *Front. Microbiol.*, 25, 2015). Also shown are estimates of the relative abundance of all genera of methanotrophs (red line) and methanogens (blue line) as a function of depth. Rice paddies are the largest contributor to agricultural methane production. The estimates were based on extraction and analysis of ribosomal RNA from the soil.

**Figure 22.35**

D. Justify the selection of these measurements of the concentrations of two types of microbes and the gases that are consumed or produced to the development of a quantitative understanding of the habitat range of both groups and the control of methane release from rice fields.

83. The human gut provides a habitat for approximately 100 trillion bacteria. Some sources claim that the surface area of the cells lining the small and large intestines is between 150 and 300 square meters and compare this area to that of a tennis court. Recent measurements, however, show that the surface area of the gut is closer to that of a studio apartment (Helander and Fandriks, *Jour. Gastro*, 2014) and is roughly 50 square meters.

A. Calculate the cellular surface area of the 100 trillion ( $10^{14}$ ) microbes in the typical human gut, assuming that the cells are spherical with an average radius of 0.001 mm. Use this calculated surface area to predict the relative rates of procurement of nutrients by both microbes and the host cells lining the large and small intestines.

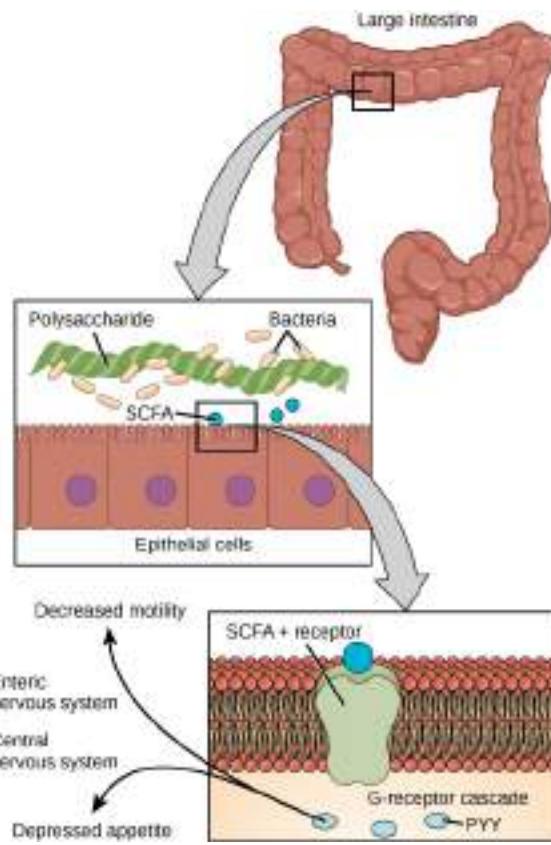

Humans compete with microbes for nutrients, but the relationship is mutually beneficial. Between 10 and 30% of ingested food remains undigested before reaching the large intestine. Some microbial waste products, particularly  $\text{H}_2$  and  $\text{CH}_4$ , are not resources for the host. But short-chain fatty acids like acetic, propionic, and butyric acids are resources that microbes extract from the

undigested fraction. The large intestine of the adult human has a length of approximately 1.5 meters with a volume between 6 and 7 liters. The total volume of gut microbes is just a few hundred milliliters.

B. Predict the length of a large intestine with equivalent recovery of resources and the same transit times through the bowel if, rather than 100 trillion organisms with a total volume of 1 L, there were 100 billion ( $10^{11}$ ) organisms, each with a volume of  $10^{-8}$  mL (the approximate volume of the epithelial cells lining the intestine).

The relationship between gut microbes and their host is more complex than simple resource recovery, as shown in the figure of the microbiome below. PYY is a hormone that works with the enteric nervous system lining the intestinal wall to cause changes in the period of contractions of muscles (motility) that push material through the intestine.

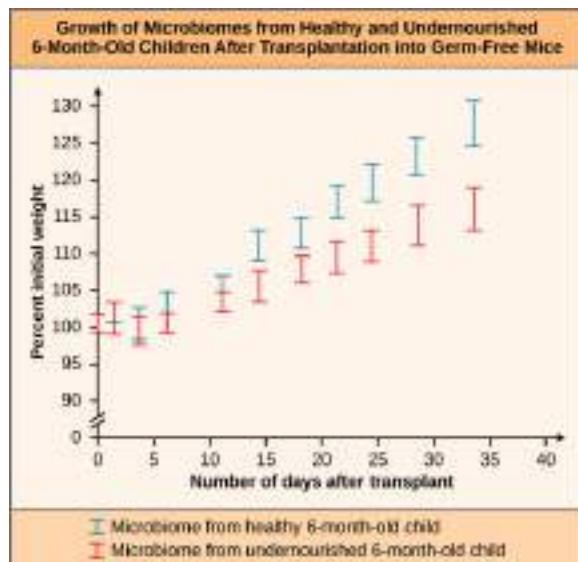

C. Based on the diagram, summarize the regulation of appetite by the microbiome and the elimination of waste by the host in terms of feedback loops and chemical signaling.

**Figure 22.36**

The microbial population of the intestine is referred to as the microbiome. Undernutrition and obesity are both symptoms of malnutrition, and populations of the microbiome vary with the type of malnutrition (Brown et al., *Nutr Clin Pract*, 2012). The microbiome of humans

can be transplanted into germ-free (GF) mice to observe the effects of diet in a controlled experiment of relatively short duration. The microbiomes of healthy and undernourished 6-month-old children were transplanted into GF mice whose growth is graphed below. Growth in both length and weight were reduced when the source of the microbiome was the undernourished child (after Blanton et al., *Science*, 2016). Both groups of mice were provided with the same nutritional resources.

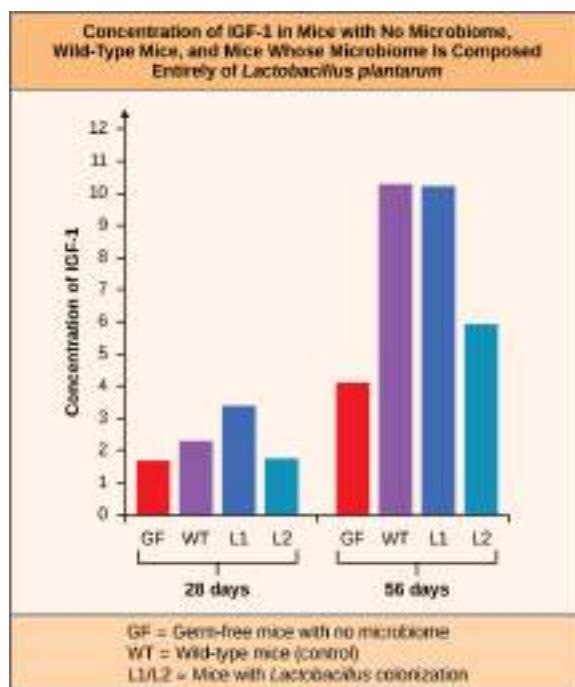

**Figure 22.37**

D. **Pose** two scientific **questions** that, when investigated, could lead to a solution for the stunting of growth caused by undernourishment in early infancy that affects millions of children.

Human growth hormone stimulates the release of insulin-like growth factor 1 (IGF-1). IGF-1 is a messenger that activates the production of bone cells called osteocytes.

The data (after Schwarzer et al., *Science*, 2016) show concentrations of this growth factor in mice with no microbiome (GF), wild-type mice whose microbiome and growth provide a control (WT), and mice whose microbiome population is composed entirely of *Lactobacillus plantarum* (two strains labeled L1 and L2). *Lactobacillus* is one of many hundred genera of microbial inhabitants of a healthy human intestine.

**Figure 22.38**

E. **Analyze** these data in terms of the potential for disruption of human bone growth due to loss or reduction in diversity of the microbiome.

# 23 | PLANT FORM AND PHYSIOLOGY

**Figure 23.1** A locust leaf consists of leaflets arrayed along a central midrib. Each leaflet is a complex photosynthetic machine, exquisitely adapted to capture sunlight and carbon dioxide. An intricate vascular system supplies the leaf with water and minerals, and exports the products of photosynthesis. (credit: modification of work by Todd Petit)

## Chapter Outline

- 23.1: The Plant Body**
- 23.2: Stems**
- 23.3: Roots**
- 23.4: Leaves**
- 23.5: Transport of Water and Solutes in Plants**
- 23.6: Plant Sensory Systems and Responses**

## Introduction

Plants are as essential to human existence as land, water, and air. Without plants, our day-to-day lives would be impossible because without oxygen from photosynthesis, aerobic life cannot be sustained. From providing food and shelter to serving as a source of medicines, oils, perfumes, and industrial products, plants provide humans with numerous valuable resources.

When you think of plants, those that first come to mind are likely to be vascular plants. These plants have tissues that conduct food and water (the word “vascular” means “having vessels”). While each vascular plant species is unique, all are made up of a plant body consisting of stems, roots, and leaves. They also all transport water, minerals, and sugars produced through photosynthesis through the plant body using the same mechanism, and they all respond to environmental factors, such as light, gravity, competition, temperature, and predation. Scientists recently discovered that two plants, the giant goldenrod and spicebush, each make five different compounds that disrupt the life cycles of insect pests. Further investigation into the chemicals could lead to a new class of pesticides.<sup>[1]</sup> You can read more about it in **ScienceNews magazine** (<http://openstaxcollege.org/l/32pest>) .

Raikhel, Yeon Ho Je, and Sang Woon Shin. “Identification of Plant Compounds that Disrupt the Insect Juvenile Hormone Receptor Complex.” PNAS 112.6 (2015) : 1733–1738; published ahead of print January 26, 2015, doi: 10.1073/pnas.1424386112

## 23.1 | The Plant Body

In this section, you will explore the following questions:

- What are differences between the shoot organ system and the root organ system?
- What are differences between meristematic tissues and permanent tissues?
- What are the three regions where plant growth occurs?
- What are the role of dermal tissues, vascular tissues, and ground tissues?
- What is the difference between simple plant tissues and complex plant tissues?

### Connection for AP® Courses

Much of the content in this chapter is not within the scope of AP®, including information about the different kinds of tissues that comprise the plant body. However, the evolution of vascular tissue made possible the transition of plants from aquatic to terrestrial environments. Xylem and phloem transport water, minerals, and sugars produced through photosynthesis through the plant body (see the **Transport of Water and Solutes in Plants** module). In addition all plant species respond to environmental factors, such as light, gravity, competition, temperature, and predation (see the **Plant Sensory Systems and Responses** module). Like animals, plants contain cells with organelles, in which specific metabolic activities occur, and specialized tissues and organs. Unlike animals, plant use energy from sunlight to synthesize sugars during photosynthesis—creating the food that supports life on this planet. Without plants, life on Earth could not exist.

With the exception of vascular tissue—which we will explore in detail in the **Transport of Water and Solutes in Plants** module—information presented in this section, and the examples highlighted, does *not* align to the content and AP® Learning Objectives outlined in the AP® Curriculum Framework.

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 2.3][APLO 2.4][APLO 2.28][APLO 4.15][APLO 4.14][APLO 4.21]

Like eukaryotes, plants contain cells with organelles in which specific metabolic activities take place. Unlike animals, however, plants use energy from sunlight to form sugars during photosynthesis. In addition, plant cells have cell walls, plastids, and a large central vacuole: structures that are not found in animal cells. Each of these cellular structures plays a specific role in plant structure and function.

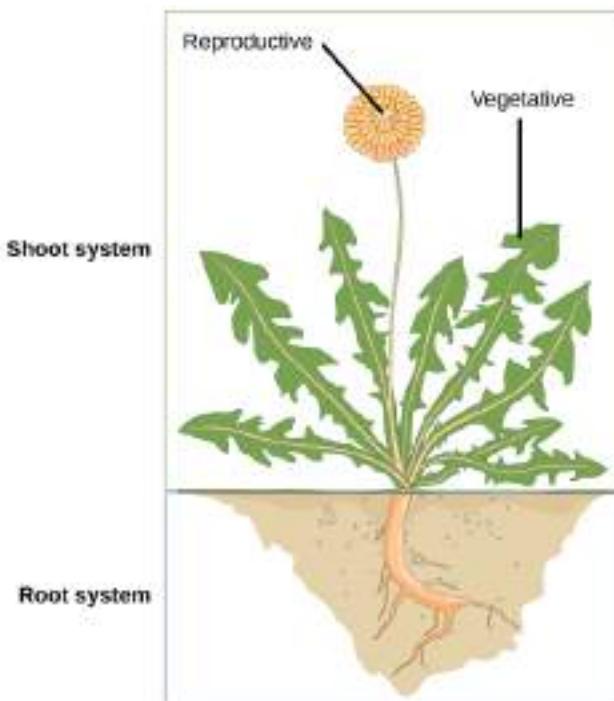

Watch **Botany Without Borders** ([http://openstaxcollege.org/l/botany\\_wo\\_bord](http://openstaxcollege.org/l/botany_wo_bord)) , a video produced by the Botanical Society of America about the importance of plants.

When the link opens to the page “Botany Without Borders” click on the menu item, “Plants Are Cool Too!” View the videoAngiosperms: The Secrets of Flowers, by Botanical Society of America (BSA) member Kate March, and answer the question below.Which group of plants dominates the landscape on Earth?

- conifers
- mosses
- ferns
- flowering plants

## Plant Organ Systems

In plants, just as in animals, similar cells working together form a tissue. When different types of tissues work together to perform a unique function, they form an organ; organs working together form organ systems. Vascular plants have two distinct organ systems: a shoot system, and a root system. The **shoot system** consists of two portions: the vegetative (non-reproductive) parts of the plant, such as the leaves and the stems, and the reproductive parts of the plant, which include flowers and fruits. The shoot system generally grows above ground, where it absorbs the light needed for photosynthesis. The **root system**, which supports the plants and absorbs water and minerals, is usually underground. **Figure 23.2** shows the organ systems of a typical plant.

**Figure 23.2** The shoot system of a plant consists of leaves, stems, flowers, and fruits. The root system anchors the plant while absorbing water and minerals from the soil.

## Plant Tissues

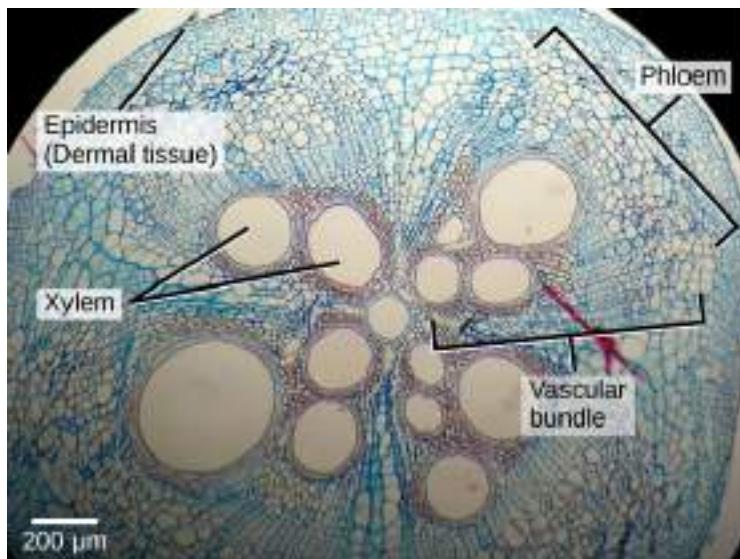

Plants are multicellular eukaryotes with tissue systems made of various cell types that carry out specific functions. Plant tissue systems fall into one of two general types: meristematic tissue, and permanent (or non-meristematic) tissue. Cells of the meristematic tissue are found in **meristems**, which are plant regions of continuous cell division and growth. **Meristematic tissue** cells are either undifferentiated or incompletely differentiated, and they continue to divide and contribute to the growth of the plant. In contrast, **permanent tissue** consists of plant cells that are no longer actively dividing.

Meristematic tissues consist of three types, based on their location in the plant. **Apical meristems** contain meristematic tissue located at the tips of stems and roots, which enable a plant to extend in length. **Lateral meristems** facilitate growth in thickness or girth in a maturing plant. **Intercalary meristems** occur only in monocots, at the bases of leaf blades and at nodes (the areas where leaves attach to a stem). This tissue enables the monocot leaf blade to increase in length from the leaf base; for example, it allows lawn grass leaves to elongate even after repeated mowing.

Meristems produce cells that quickly differentiate, or specialize, and become permanent tissue. Such cells take on specific roles and lose their ability to divide further. They differentiate into three main types: dermal, vascular, and ground tissue. **Dermal tissue** covers and protects the plant, and **vascular tissue** transports water, minerals, and sugars to different parts of the plant. **Ground tissue** serves as a site for photosynthesis, provides a supporting matrix for the vascular tissue, and helps to store water and sugars.

Secondary tissues are either simple (composed of similar cell types) or complex (composed of different cell types). Dermal tissue, for example, is a simple tissue that covers the outer surface of the plant and controls gas exchange. Vascular tissue is an example of a complex tissue, and is made of two specialized conducting tissues: xylem and phloem. Xylem tissue transports water and nutrients from the roots to different parts of the plant, and includes three different cell types: vessel

elements and tracheids (both of which conduct water), and xylem parenchyma. Phloem tissue, which transports organic compounds from the site of photosynthesis to other parts of the plant, consists of four different cell types: sieve cells (which conduct photosynthates), companion cells, phloem parenchyma, and phloem fibers. Unlike xylem conducting cells, phloem conducting cells are alive at maturity. The xylem and phloem always lie adjacent to each other (**Figure 23.3**). In stems, the xylem and the phloem form a structure called a **vascular bundle**; in roots, this is termed the **vascular stele** or **vascular cylinder**.

**Figure 23.3** This light micrograph shows a cross section of a squash (*Cucurbita maxima*) stem. Each teardrop-shaped vascular bundle consists of large xylem vessels toward the inside and smaller phloem cells toward the outside. Xylem cells, which transport water and nutrients from the roots to the rest of the plant, are dead at functional maturity. Phloem cells, which transport sugars and other organic compounds from photosynthetic tissue to the rest of the plant, are living. The vascular bundles are encased in ground tissue and surrounded by dermal tissue. (credit: modification of work by "(biophotos)"/Flickr; scale-bar data from Matt Russell)

## 23.2 | Stems

In this section, you will explore the following questions:

- What is the main function and basic structure of a plant stem?
- What are the roles of dermal tissues, vascular tissues, and ground tissues?
- What is the difference between primary growth and secondary growth in stems?
- What is the origin of annual rings in stems? How are annual rings used to approximate the age of a tree?
- What are examples of modified stems?

### Connection for AP® Courses

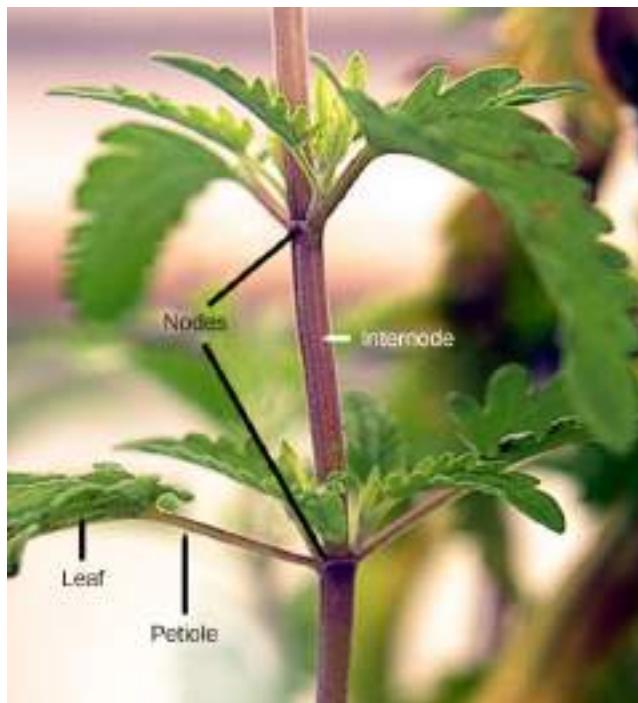

Much content described in this section is not within the scope of AP®. You are not required to memorize the different types of tissues that comprise the plant stem. However, in the **Transport of Water and Solutes in Plants** module we will explore in detail the roles vascular tissues (xylem and phloem), epidermal guard cells, **stomata**, and trichomes play in **transpiration**, the uptake of carbon dioxide and the release of oxygen and water vapor. **Trichomes**—hair-like structures on the epidermal surface—also defend leaves against predation (see the **Plant Sensory Systems and Responses** module).

Except for the concepts described in the AP® Connection, information presented in this module, and the examples highlighted, does *not* align to the content and AP® Learning Objectives outlined in the AP® Curriculum Framework.

Stems are a part of the shoot system of a plant. They may range in length from a few millimeters to hundreds of meters, and also vary in diameter, depending on the plant type. Stems are usually above ground, although the stems of some plants, such as the potato, also grow underground. Stems may be herbaceous (soft) or woody in nature. Their main function is to

provide support to the plant, holding leaves, flowers and buds; in some cases, stems also store food for the plant. A stem may be unbranched, like that of a palm tree, or it may be highly branched, like that of a magnolia tree. The stem of the plant connects the roots to the leaves, helping to transport absorbed water and minerals to different parts of the plant. It also helps to transport the products of photosynthesis, namely sugars, from the leaves to the rest of the plant.

Plant stems, whether above or below ground, are characterized by the presence of nodes and internodes (Figure 23.4). **Nodes** are points of attachment for leaves, aerial roots, and flowers. The stem region between two nodes is called an **internode**. The stalk that extends from the stem to the base of the leaf is the petiole. An **axillary bud** is usually found in the axil—the area between the base of a leaf and the stem—where it can give rise to a branch or a flower. The apex (tip) of the shoot contains the apical meristem within the **apical bud**.

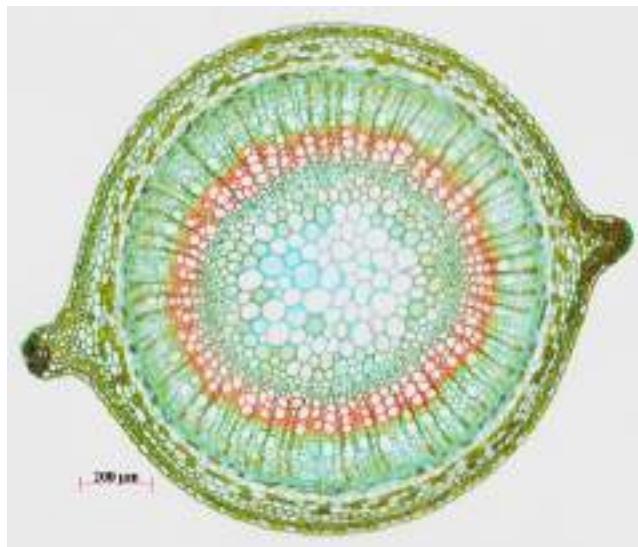

**Figure 23.4** Leaves are attached to the plant stem at areas called nodes. An internode is the stem region between two nodes. The petiole is the stalk connecting the leaf to the stem. The leaves just above the nodes arose from axillary buds.

## Stem Anatomy

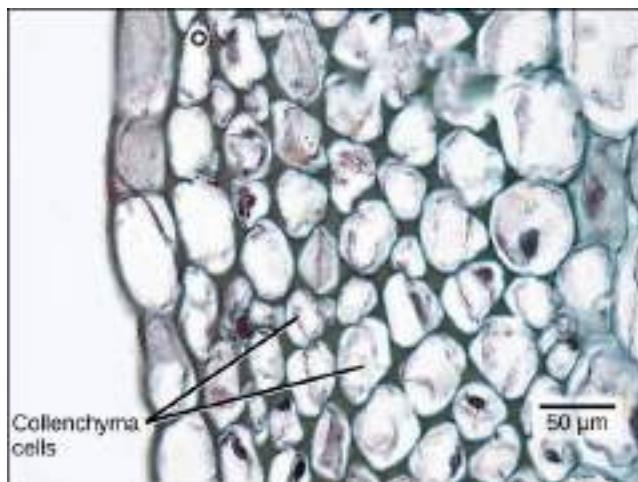

The stem and other plant organs arise from the ground tissue, and are primarily made up of simple tissues formed from three types of cells: parenchyma, collenchyma, and sclerenchyma cells.

**Parenchyma cells** are the most common plant cells (Figure 23.5). They are found in the stem, the root, the inside of the leaf, and the pulp of the fruit. Parenchyma cells are responsible for metabolic functions, such as photosynthesis, and they help repair and heal wounds. Some parenchyma cells also store starch.

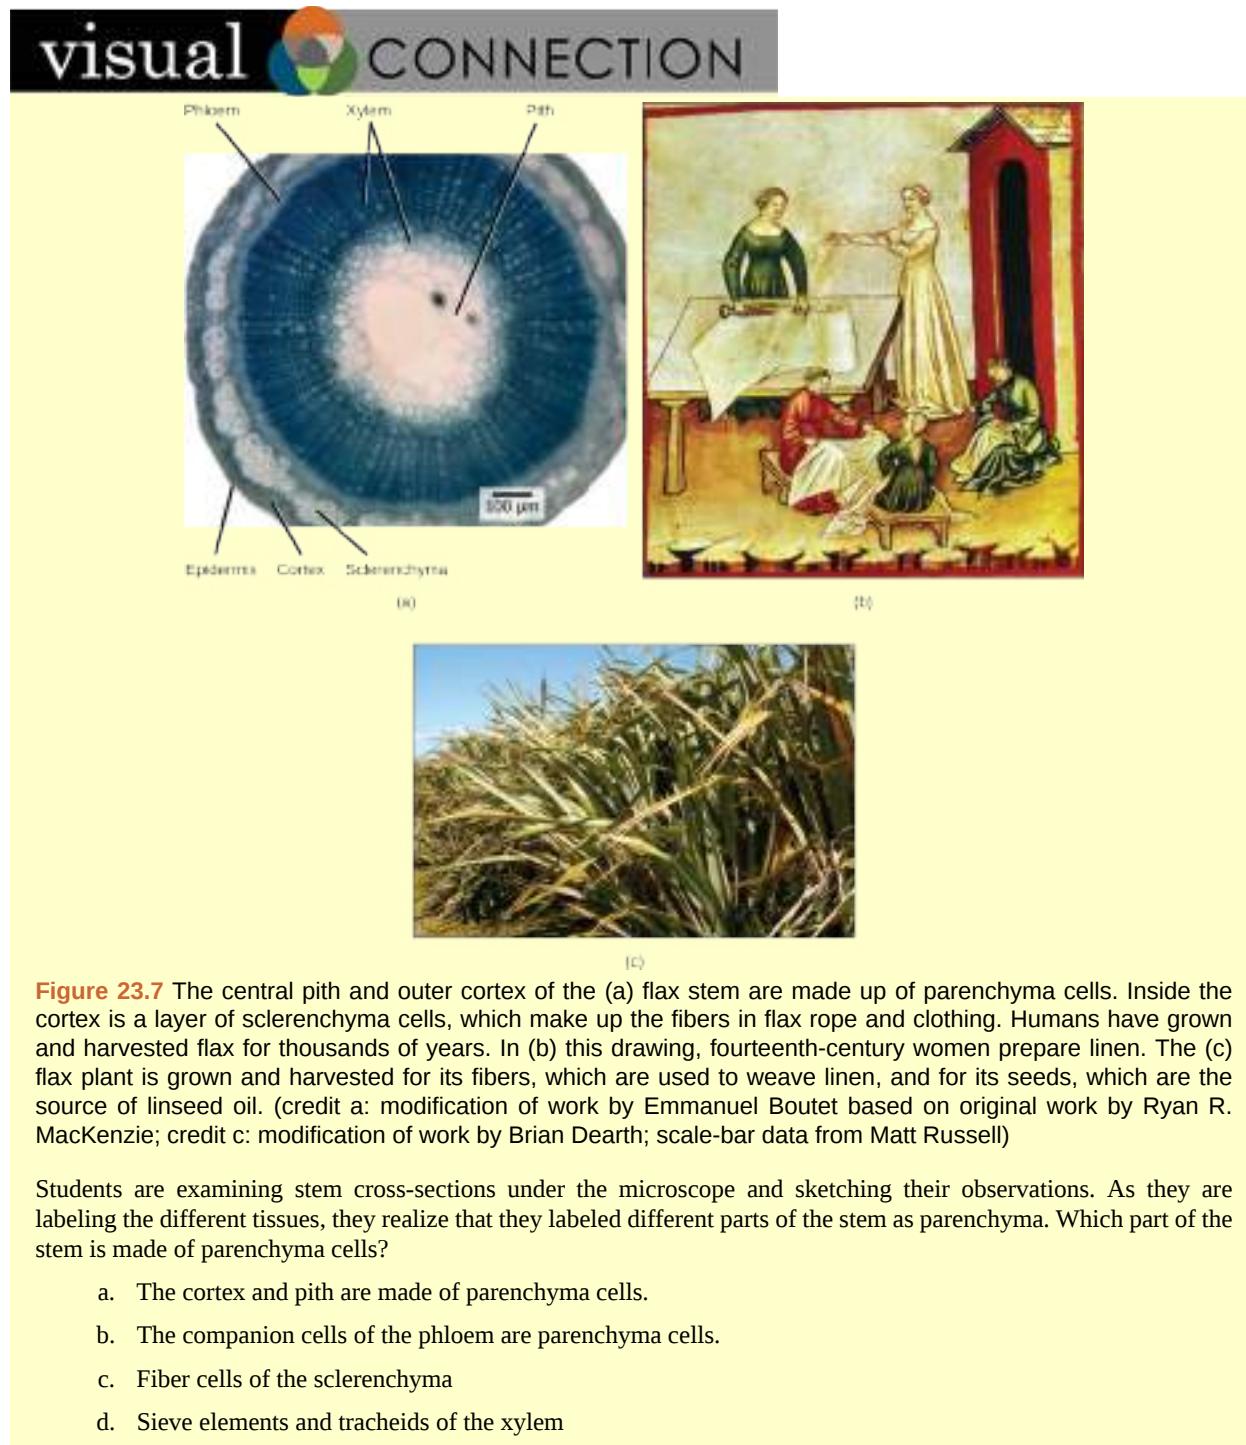

**Figure 23.5** The stem of common St John's Wort (*Hypericum perforatum*) is shown in cross section in this light micrograph. The central pith (greenish-blue, in the center) and peripheral cortex (narrow zone 3–5 cells thick just inside the epidermis) are composed of parenchyma cells. Vascular tissue composed of xylem (red) and phloem tissue (green, between the xylem and cortex) surrounds the pith. (credit: Rolf-Dieter Mueller)

**Collenchyma cells** are elongated cells with unevenly thickened walls (Figure 23.6). They provide structural support, mainly to the stem and leaves. These cells are alive at maturity and are usually found below the epidermis. The “strings” of a celery stalk are an example of collenchyma cells.

**Figure 23.6** Collenchyma cell walls are uneven in thickness, as seen in this light micrograph. They provide support to plant structures. (credit: modification of work by Carl Szczerski; scale-bar data from Matt Russell)

**Sclerenchyma cells** also provide support to the plant, but unlike collenchyma cells, many of them are dead at maturity. There are two types of sclerenchyma cells: fibers and sclereids. Both types have secondary cell walls that are thickened with deposits of lignin, an organic compound that is a key component of wood. Fibers are long, slender cells; sclereids are smaller-sized. Sclereids give pears their gritty texture. Humans use sclerenchyma fibers to make linen and rope (Figure 23.7).

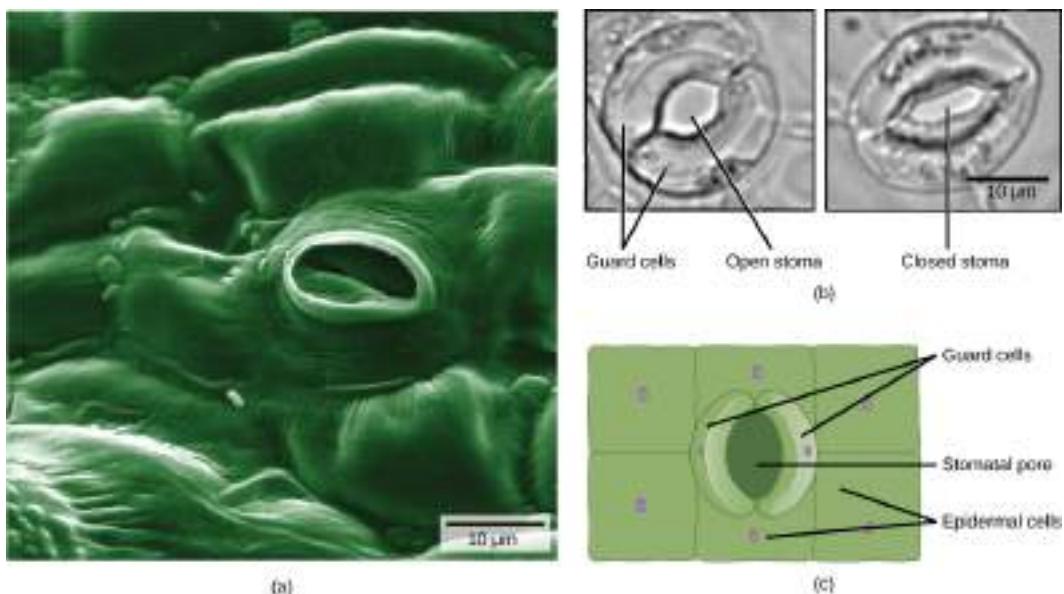

Like the rest of the plant, the stem has three tissue systems: dermal, vascular, and ground tissue. Each is distinguished by characteristic cell types that perform specific tasks necessary for the plant's growth and survival.

#### Dermal Tissue

The dermal tissue of the stem consists primarily of **epidermis**, a single layer of cells covering and protecting the underlying tissue. Woody plants have a tough, waterproof outer layer of cork cells commonly known as **bark**, which further protects the plant from damage. Epidermal cells are the most numerous and least differentiated of the cells in the epidermis. The epidermis of a leaf also contains openings known as **stomata**, through which the exchange of gases takes place (Figure

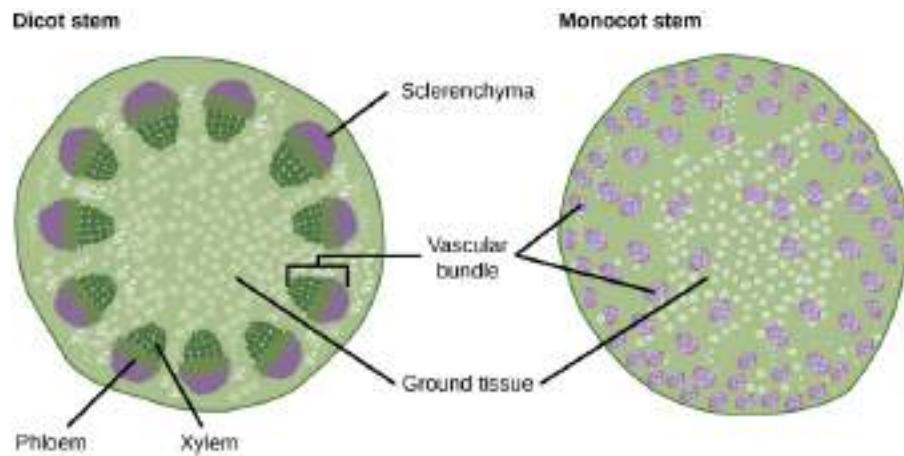

**23.8).** Two cells, known as **guard cells**, surround each leaf stoma, controlling its opening and closing and thus regulating the uptake of carbon dioxide and the release of oxygen and water vapor. Trichomes are hair-like structures on the epidermal surface. They help to reduce transpiration (the loss of water by aboveground plant parts), increase solar reflectance, and store compounds that defend the leaves against predation by herbivores.

**Figure 23.8** Openings called stomata (singular: stoma) allow a plant to take up carbon dioxide and release oxygen and water vapor. The (a) colorized scanning-electron micrograph shows a closed stoma of a dicot. Each stoma is flanked by two guard cells that regulate its (b) opening and closing. The (c) guard cells sit within the layer of epidermal cells (credit a: modification of work by Louisa Howard, Rippel Electron Microscope Facility, Dartmouth College; credit b: modification of work by June Kwak, University of Maryland; scale-bar data from Matt Russell)

### Vascular Tissue

The xylem and phloem that make up the vascular tissue of the stem are arranged in distinct strands called vascular bundles, which run up and down the length of the stem. When the stem is viewed in cross section, the vascular bundles of dicot stems are arranged in a ring. In plants that live for more than one year, the individual bundles grow together and produce the characteristic growth rings. In monocot stems, the vascular bundles are randomly scattered throughout the ground tissue (**Figure 23.9**).

**Figure 23.9** In (a) dicot stems, vascular bundles are arranged around the periphery of the ground tissue. The xylem tissue is located toward the interior of the vascular bundle, and phloem is located toward the exterior. Sclerenchyma fibers cap the vascular bundles. In (b) monocot stems, vascular bundles composed of xylem and phloem tissues are scattered throughout the ground tissue.

Xylem tissue has three types of cells: xylem parenchyma, tracheids, and vessel elements. The latter two types conduct water and are dead at maturity. **Tracheids** are xylem cells with thick secondary cell walls that are lignified. Water moves from one tracheid to another through regions on the side walls known as pits, where secondary walls are absent. **Vessel elements** are

xylem cells with thinner walls; they are shorter than tracheids. Each vessel element is connected to the next by means of a perforation plate at the end walls of the element. Water moves through the perforation plates to travel up the plant.

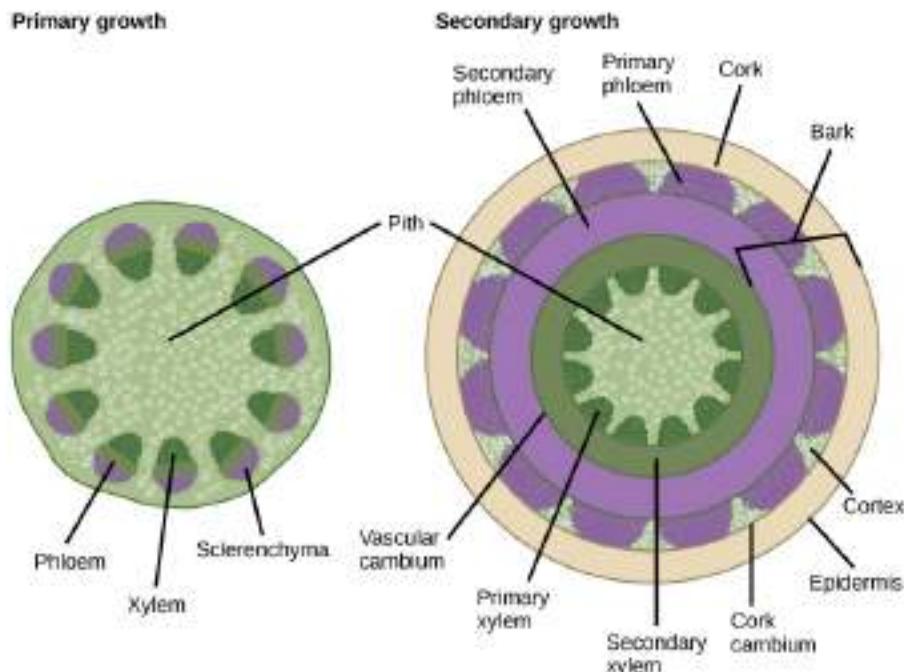

Phloem tissue is composed of sieve-tube cells, companion cells, phloem parenchyma, and phloem fibers. A series of **sieve-tube cells** (also called sieve-tube elements) are arranged end to end to make up a long sieve tube, which transports organic substances such as sugars and amino acids. The sugars flow from one sieve-tube cell to the next through perforated sieve plates, which are found at the end junctions between two cells. Although still alive at maturity, the nucleus and other cell components of the sieve-tube cells have disintegrated. **Companion cells** are found alongside the sieve-tube cells, providing them with metabolic support. The companion cells contain more ribosomes and mitochondria than the sieve-tube cells, which lack some cellular organelles.

### Ground Tissue

Ground tissue is mostly made up of parenchyma cells, but may also contain collenchyma and sclerenchyma cells that help support the stem. The ground tissue towards the interior of the vascular tissue in a stem or root is known as **pith**, while the layer of tissue between the vascular tissue and the epidermis is known as the **cortex**.

## Growth in Stems

Growth in plants occurs as the stems and roots lengthen. Some plants, especially those that are woody, also increase in thickness during their life span. The increase in length of the shoot and the root is referred to as **primary growth**, and is the result of cell division in the shoot apical meristem. **Secondary growth** is characterized by an increase in thickness or girth of the plant, and is caused by cell division in the lateral meristem. **Figure 23.10** shows the areas of primary and secondary growth in a plant. Herbaceous plants mostly undergo primary growth, with hardly any secondary growth or increase in thickness. Secondary growth or “wood” is noticeable in woody plants; it occurs in some dicots, but occurs very rarely in monocots.

**Figure 23.10** In woody plants, primary growth is followed by secondary growth, which allows the plant stem to increase in thickness or girth. Secondary vascular tissue is added as the plant grows, as well as a cork layer. The bark of a tree extends from the vascular cambium to the epidermis.

Some plant parts, such as stems and roots, continue to grow throughout a plant's life: a phenomenon called indeterminate growth. Other plant parts, such as leaves and flowers, exhibit determinate growth, which ceases when a plant part reaches a particular size.

### Primary Growth

Most primary growth occurs at the apices, or tips, of stems and roots. Primary growth is a result of rapidly dividing cells in the apical meristems at the shoot tip and root tip. Subsequent cell elongation also contributes to primary growth. The growth of shoots and roots during primary growth enables plants to continuously seek water (roots) or sunlight (shoots).

The influence of the apical bud on overall plant growth is known as apical dominance, which diminishes the growth of axillary buds that form along the sides of branches and stems. Most coniferous trees exhibit strong apical dominance, thus producing the typical conical Christmas tree shape. If the apical bud is removed, then the axillary buds will start forming lateral branches. Gardeners make use of this fact when they prune plants by cutting off the tops of branches, thus encouraging the axillary buds to grow out, giving the plant a bushy shape.

Watch this **BBC Nature video** ([http://openstaxcollege.org/l/motion\\_plants](http://openstaxcollege.org/l/motion_plants)) showing how time-lapse photography captures plant growth at high speed.

The video you watched showed time lapse photography of the growth of a stem. Which of these is a fast response in a plant that was not recorded in the video?

- a. opening of a flower
- b. tendrils looping around a support
- c. growth of an apical bud
- d. closing of leaflets on a lightly touched mimosa leaf

### Secondary Growth

The increase in stem thickness that results from secondary growth is due to the activity of the lateral meristems, which are lacking in herbaceous plants. Lateral meristems include the vascular cambium and, in woody plants, the cork cambium (see **Figure 23.10**). The vascular cambium is located just outside the primary xylem and to the interior of the primary phloem. The cells of the vascular cambium divide and form secondary xylem (tracheids and vessel elements) to the inside, and secondary phloem (sieve elements and companion cells) to the outside. The thickening of the stem that occurs in secondary growth is due to the formation of secondary phloem and secondary xylem by the vascular cambium, plus the action of cork cambium, which forms the tough outermost layer of the stem. The cells of the secondary xylem contain lignin, which provides hardness and strength.

In woody plants, cork cambium is the outermost lateral meristem. It produces cork cells (bark) containing a waxy substance known as suberin that can repel water. The bark protects the plant against physical damage and helps reduce water loss. The cork cambium also produces a layer of cells known as phellogen, which grows inward from the cambium. The cork cambium, cork cells, and phellogen are collectively termed the **periderm**. The periderm substitutes for the epidermis in mature plants. In some plants, the periderm has many openings, known as **lenticels**, which allow the interior cells to exchange gases with the outside atmosphere (**Figure 23.11**). This supplies oxygen to the living and metabolically active cells of the cortex, xylem and phloem.

**Figure 23.11** Lenticels on the bark of this cherry tree enable the woody stem to exchange gases with the surrounding atmosphere. (credit: Roger Griffith)

### Annual Rings

The activity of the vascular cambium gives rise to annual growth rings. During the spring growing season, cells of the secondary xylem have a large internal diameter and their primary cell walls are not extensively thickened. This is known as early wood, or spring wood. During the fall season, the secondary xylem develops thickened cell walls, forming late wood, or autumn wood, which is denser than early wood. This alternation of early and late wood is due largely to a seasonal decrease in the number of vessel elements and a seasonal increase in the number of tracheids. It results in the formation of an annual ring, which can be seen as a circular ring in the cross section of the stem ([Figure 23.12](#)). An examination of the number of annual rings and their nature (such as their size and cell wall thickness) can reveal the age of the tree and the prevailing climatic conditions during each season.

**Figure 23.12** The rate of wood growth increases in summer and decreases in winter, producing a characteristic ring for each year of growth. Seasonal changes in weather patterns can also affect the growth rate—note how the rings vary in thickness. (credit: Adrian Pingstone)

## Stem Modifications

Some plant species have modified stems that are especially suited to a particular habitat and environment ([Figure 23.13](#)). A **rhizome** is a modified stem that grows horizontally underground and has nodes and internodes. Vertical shoots may arise from the buds on the rhizome of some plants, such as ginger and ferns. **Corms** are similar to rhizomes, except they are

more rounded and fleshy (such as in gladiolus). Corms contain stored food that enables some plants to survive the winter. **Stolons** are stems that run almost parallel to the ground, or just below the surface, and can give rise to new plants at the nodes. **Runners** are a type of stolon that runs above the ground and produces new clone plants at nodes at varying intervals: strawberries are an example. **Tubers** are modified stems that may store starch, as seen in the potato (*Solanum* sp.). Tubers arise as swollen ends of stolons, and contain many adventitious or unusual buds (familiar to us as the “eyes” on potatoes). A **bulb**, which functions as an underground storage unit, is a modification of a stem that has the appearance of enlarged fleshy leaves emerging from the stem or surrounding the base of the stem, as seen in the iris.

**Figure 23.13** Stem modifications enable plants to thrive in a variety of environments. Shown are (a) ginger (*Zingiber officinale*) rhizomes, (b) a carrion flower (*Amorphophallus titanum*) corm (c) Rhodes grass (*Chloris gayana*) stolons, (d) strawberry (*Fragaria ananassa*) runners, (e) potato (*Solanum tuberosum*) tubers, and (f) red onion (*Allium*) bulbs. (credit a: modification of work by Maja Dumat; credit c: modification of work by Harry Rose; credit d: modification of work by Rebecca Siegel; credit e: modification of work by Scott Bauer, USDA ARS; credit f: modification of work by Stephen Ausmus, USDA ARS)

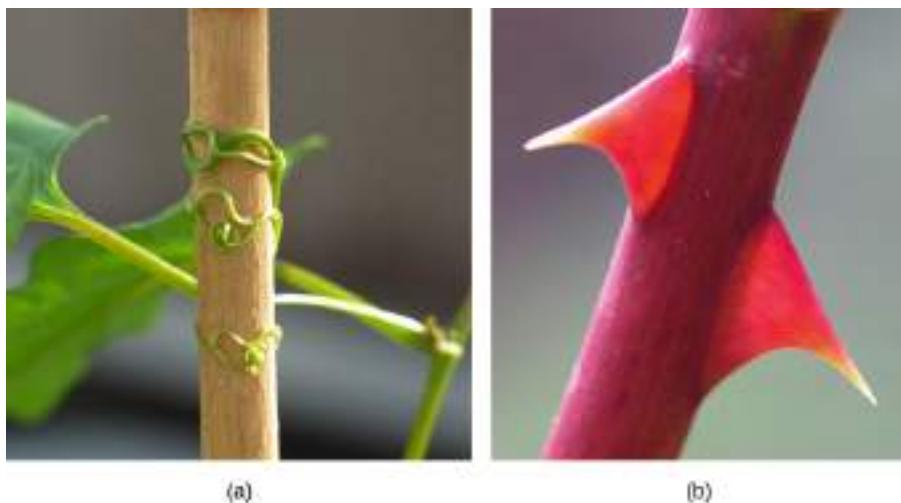

Watch botanist Wendy Hodgson, of Desert Botanical Garden in Phoenix, Arizona, explain how agave plants were cultivated for food hundreds of years ago in the Arizona desert in this [video: \(http://openstaxcollege.org/l/ancient\\_crop\)](http://openstaxcollege.org/l/ancient_crop) *Finding the Roots of an Ancient Crop*.

Agave plants were cultivated for hundreds of years by Pre-Columbian American populations. The sap was considered a good source of \_\_\_\_\_.

- sweetener for drinks and cooking
- proteins to supplement the daily diet
- lipids for cooking and baking
- starch for thickening desserts and stews

Some aerial modifications of stems are tendrils and thorns (Figure 23.14). **Tendrils** are slender, twining strands that enable a plant (like a vine or pumpkin) to seek support by climbing on other surfaces. **Thorns** are modified branches appearing as sharp outgrowths that protect the plant; common examples include roses, Osage orange and devil's walking stick.

**Figure 23.14** Found in southeastern United States, (a) buckwheat vine (*Brunnichia ovata*) is a weedy plant that climbs with the aid of tendrils. This one is shown climbing up a wooden stake. (b) Thorns are modified branches. (credit a: modification of work by Christopher Meloche, USDA ARS; credit b: modification of work by "macrophile"/Flickr)

## 23.3 | Roots

In this section, you will explore the following questions:

- What are the two types of root system?
- What are the three zones of the root tip and what is the role of each in root growth?
- What is the structure of the root?
- What are examples of modified roots?

### Connection for AP<sup>®</sup> Courses

Much content described in this section, specifically root anatomy, is not within the scope of AP<sup>®</sup>. However, in the **Transport of Water and Solutes in Plants** module, we will explore the role of roots in absorbing water necessary for photosynthesis, transporting minerals and other nutrients, and storing carbohydrates.

When we explored mitosis in the Cell Reproduction chapter, you may have examined a root meristem under the microscope. The meristem is comprised of actively dividing cells. However, just like animal organs and organ systems, plant structures, including roots, interact to provide specific functions. For example, water is absorbed through the root system and travels upward through xylem to the leaves, where it is used in photosynthesis. (See the **Transport of Water and Solutes in Plants** module.)

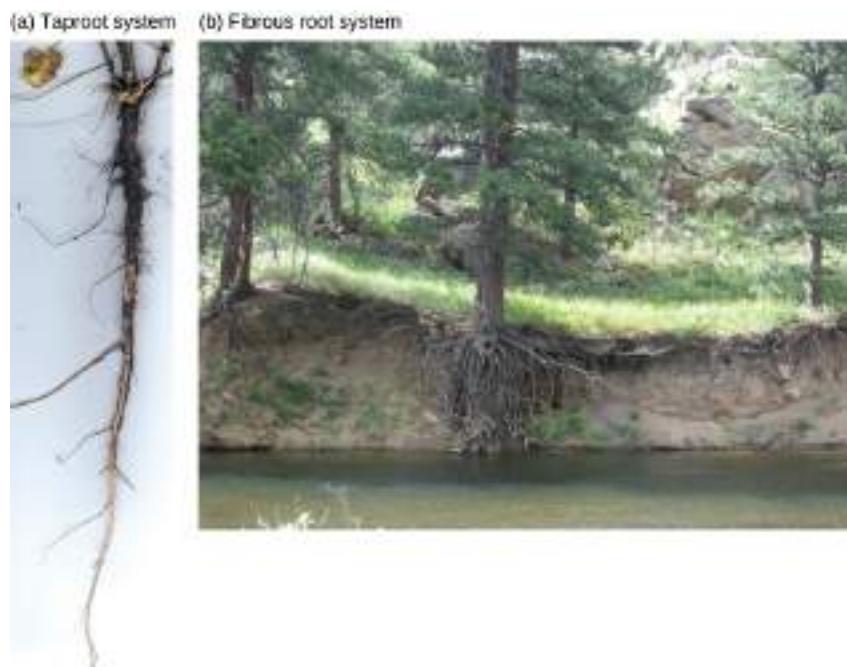

With the exceptions described in the AP<sup>®</sup> Connection, information presented in this section, and the examples highlighted, does *not* align to the content and AP<sup>®</sup> Learning Objectives outlined in the AP<sup>®</sup> Curriculum Framework.

The roots of seed plants have three major functions: anchoring the plant to the soil, absorbing water and minerals and transporting them upwards, and storing the products of photosynthesis. Some roots are modified to absorb moisture and exchange gases. Most roots are underground. Some plants, however, also have **adventitious roots**, which emerge above the ground from the shoot.

### Types of Root Systems

Root systems are mainly of two types (Figure 23.15). Dicots have a tap root system, while monocots have a fibrous root system. A **tap root system** has a main root that grows down vertically, and from which many smaller lateral roots arise. Dandelions are a good example; their tap roots usually break off when trying to pull these weeds, and they can regrow another shoot from the remaining root. A tap root system penetrates deep into the soil. In contrast, a **fibrous root system** is located closer to the soil surface, and forms a dense network of roots that also helps prevent soil erosion (lawn grasses are a good example, as are wheat, rice, and corn). Some plants have a combination of tap roots and fibrous roots. Plants that grow

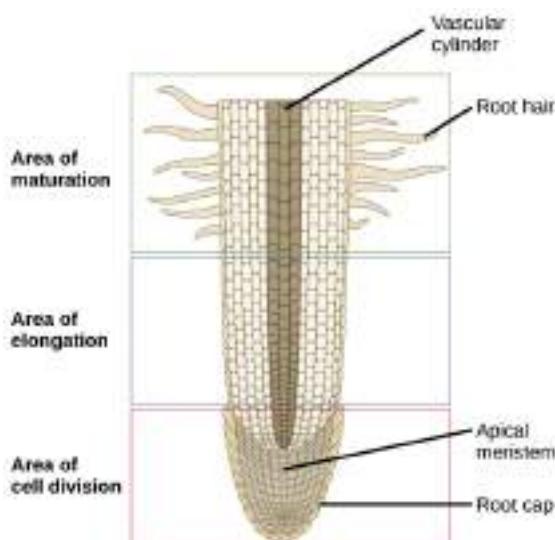

in dry areas often have deep root systems, whereas plants growing in areas with abundant water are likely to have shallower root systems.

**Figure 23.15** (a) Tap root systems have a main root that grows down, while (b) fibrous root systems consist of many small roots. (credit b: modification of work by "Austen Squarepants"/Flickr)

## Root Growth and Anatomy

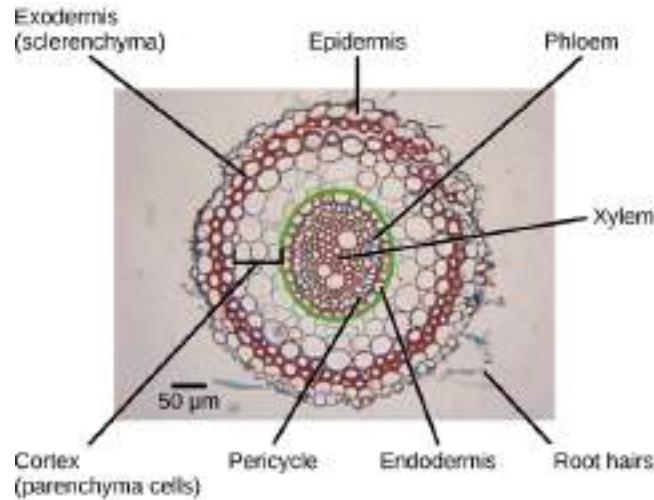

Root growth begins with seed germination. When the plant embryo emerges from the seed, the radicle of the embryo forms the root system. The tip of the root is protected by the **root cap**, a structure exclusive to roots and unlike any other plant structure. The root cap is continuously replaced because it gets damaged easily as the root pushes through soil. The root tip can be divided into three zones: a zone of cell division, a zone of elongation, and a zone of maturation and differentiation (**Figure 23.16**). The zone of cell division is closest to the root tip; it is made up of the actively dividing cells of the root meristem. The zone of elongation is where the newly formed cells increase in length, thereby lengthening the root. Beginning at the first root hair is the zone of cell maturation where the root cells begin to differentiate into special cell types. All three zones are in the first centimeter or so of the root tip.

**Figure 23.16** A longitudinal view of the root reveals the zones of cell division, elongation, and maturation. Cell division occurs in the apical meristem.

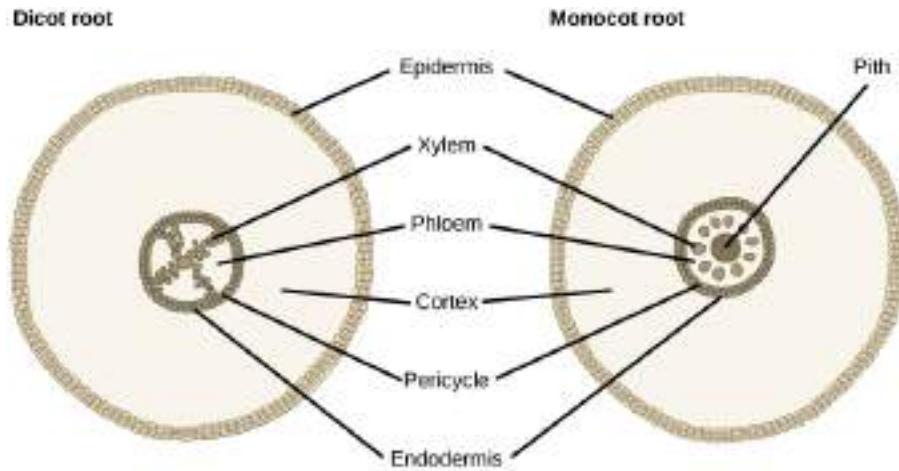

The root has an outer layer of cells called the epidermis, which surrounds areas of ground tissue and vascular tissue. The epidermis provides protection and helps in absorption. **Root hairs**, which are extensions of root epidermal cells, increase the surface area of the root, greatly contributing to the absorption of water and minerals.

Inside the root, the ground tissue forms two regions: the cortex and the pith (**Figure 23.17**). Compared to stems, roots have lots of cortex and little pith. Both regions include cells that store photosynthetic products. The cortex is between the epidermis and the vascular tissue, whereas the pith lies between the vascular tissue and the center of the root.

**Figure 23.17** Staining reveals different cell types in this light micrograph of a wheat (*Triticum*) root cross section. Sclerenchyma cells of the exodermis and xylem cells stain red, and phloem cells stain blue. Other cell types stain black. The stele, or vascular tissue, is the area inside endodermis (indicated by a green ring). Root hairs are visible outside the epidermis. (credit: scale-bar data from Matt Russell)

The vascular tissue in the root is arranged in the inner portion of the root, which is called the **stele** (**Figure 23.18**). A layer of cells known as the **endodermis** separates the stele from the ground tissue in the outer portion of the root. The endodermis is exclusive to roots, and serves as a checkpoint for materials entering the root's vascular system. A waxy substance called suberin is present on the walls of the endodermal cells. This waxy region, known as the **Casparian strip**, forces water and solutes to cross the plasma membranes of endodermal cells instead of slipping between the cells. This ensures that only materials required by the root pass through the endodermis, while toxic substances and pathogens are generally excluded. The outermost cell layer of the root's vascular tissue is the **pericycle**, an area that can give rise to lateral roots. In dicot roots, the xylem and phloem of the stele are arranged alternately in an X shape, whereas in monocot roots, the vascular tissue is arranged in a ring around the pith.

**Figure 23.18** In (left) typical dicots, the vascular tissue forms an X shape in the center of the root. In (right) typical monocots, the phloem cells and the larger xylem cells form a characteristic ring around the central pith.

## Root Modifications

Root structures may be modified for specific purposes. For example, some roots are bulbous and store starch. Aerial roots

and prop roots are two forms of aboveground roots that provide additional support to anchor the plant. Tap roots, such as carrots, turnips, and beets, are examples of roots that are modified for food storage (**Figure 23.19**).

**Figure 23.19** Many vegetables are modified roots.

Epiphytic roots enable a plant to grow on another plant. For example, the epiphytic roots of orchids develop a spongy tissue to absorb moisture. The banyan tree (*Ficus sp.*) begins as an epiphyte, germinating in the branches of a host tree; aerial roots develop from the branches and eventually reach the ground, providing additional support (**Figure 23.20**). In screwpine (*Pandanus sp.*), a palm-like tree that grows in sandy tropical soils, aboveground prop roots develop from the nodes to provide additional support.

**Figure 23.20** The (a) banyan tree, also known as the strangler fig, begins life as an epiphyte in a host tree. Aerial roots extend to the ground and support the growing plant, which eventually strangles the host tree. The (b) screwpine develops aboveground roots that help support the plant in sandy soils. (credit a: modification of work by "psyberartist"/Flickr; credit b: modification of work by David Eikhoff)

## 23.4 | Leaves

In this section, you will explore the following questions:

- What are the parts of a typical leaf?
- What is the internal structure and function of a leaf?
- What are differences between simple leaves and compound leaves? Similarities?
- What are examples of modified leaves?

### Connection for AP<sup>®</sup> Courses

Plants have specialized leaves adapted to their particular environments. For example, the leaves of plants growing in tropical rainforests have a larger surface area than cacti growing in the desert or in very cold conditions, whose smaller surface area

minimizes water loss through transpiration. A waxy **cuticle** covers the surface of all plant species to reduce the rate of water loss from the leaf surface. Other leaves may have small hairs called trichomes on the leaf surface; not only do trichomes also help reduce water loss; they also protect the leaf from herbivory by restricting insect movements or by storing toxic or bad-tasting chemicals.

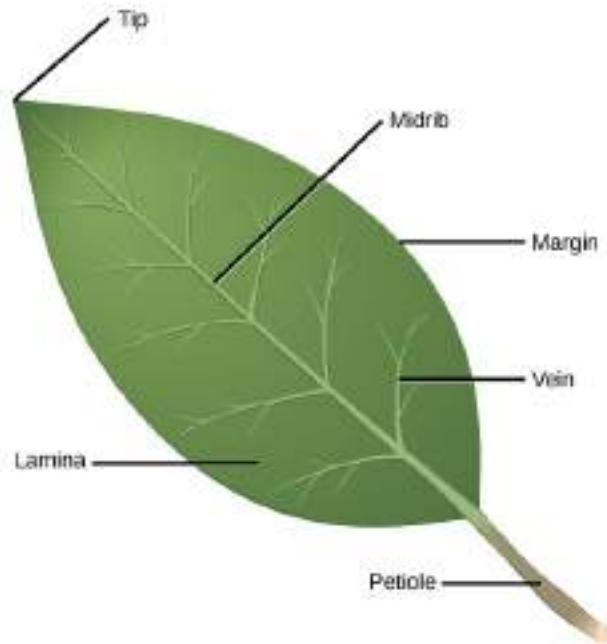

The information presented in this module does not align to the content and AP<sup>®</sup> Learning Objectives outlined in the AP<sup>®</sup> Curriculum Framework. The role of stomata, guard cells, and trichomes in transpiration are explored in the **Transport of Water and Solutes in Plants** module.

Leaves are the main sites for photosynthesis: the process by which plants synthesize food. Most leaves are usually green, due to the presence of chlorophyll in the leaf cells. However, some leaves may have different colors, caused by other plant pigments that mask the green chlorophyll.

The thickness, shape, and size of leaves are adapted to the environment. Each variation helps a plant species maximize its chances of survival in a particular habitat. Usually, the leaves of plants growing in tropical rainforests have larger surface areas than those of plants growing in deserts or very cold conditions, which are likely to have a smaller surface area to minimize water loss.

## Structure of a Typical Leaf

Each leaf typically has a leaf blade called the **lamina**, which is also the widest part of the leaf. Some leaves are attached to the plant stem by a **petiole**. Leaves that do not have a petiole and are directly attached to the plant stem are called **sessile** leaves. Small green appendages usually found at the base of the petiole are known as **stipules**. Most leaves have a midrib, which travels the length of the leaf and branches to each side to produce veins of vascular tissue. The edge of the leaf is called the margin. **Figure 23.21** shows the structure of a typical eudicot leaf.

**Figure 23.21** Deceptively simple in appearance, a leaf is a highly efficient structure.

Within each leaf, the vascular tissue forms veins. The arrangement of veins in a leaf is called the **venation** pattern. Monocots and dicots differ in their patterns of venation (**Figure 23.22**). Monocots have parallel venation; the veins run in straight lines across the length of the leaf without converging at a point. In dicots, however, the veins of the leaf have a net-like appearance, forming a pattern known as reticulate venation. One extant plant, the *Ginkgo biloba*, has dichotomous venation where the veins fork.

**Figure 23.22** (a) Tulip (*Tulipa*), a monocot, has leaves with parallel venation. The netlike venation in this (b) linden (*Tilia cordata*) leaf distinguishes it as a dicot. The (c) *Ginkgo biloba* tree has dichotomous venation. (credit a photo: modification of work by "Drewboy64"/Wikimedia Commons; credit b photo: modification of work by Roger Griffith; credit c photo: modification of work by "geishaboy500"/Flickr; credit abc illustrations: modification of work by Agnieszka Kwiecień)

## Leaf Arrangement

The arrangement of leaves on a stem is known as **phyllotaxy**. The number and placement of a plant's leaves will vary depending on the species, with each species exhibiting a characteristic leaf arrangement. Leaves are classified as either alternate, spiral, or opposite. Plants that have only one leaf per node have leaves that are said to be either alternate—meaning the leaves alternate on each side of the stem in a flat plane—or spiral, meaning the leaves are arrayed in a spiral along the stem. In an opposite leaf arrangement, two leaves arise at the same point, with the leaves connecting opposite each other along the branch. If there are three or more leaves connected at a node, the leaf arrangement is classified as **whorled**.

## Leaf Form

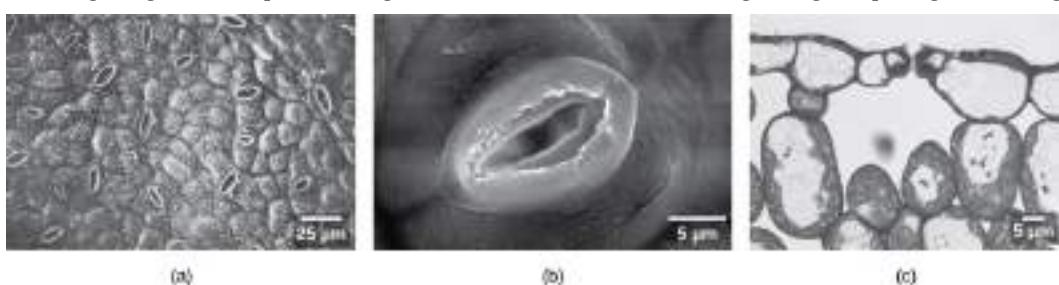

Leaves may be simple or compound (Figure 23.23). In a **simple leaf**, the blade is either completely undivided—as in the banana leaf—or it has lobes, but the separation does not reach the midrib, as in the maple leaf. In a **compound leaf**, the leaf blade is completely divided, forming leaflets, as in the locust tree. Each leaflet may have its own stalk, but is attached to the rachis. A **palmately compound leaf** resembles the palm of a hand, with leaflets radiating outwards from one point. Examples include the leaves of poison ivy, the buckeye tree, or the familiar houseplant *Schefflera* sp. (common name “umbrella plant”). **Pinnately compound leaves** take their name from their feather-like appearance; the leaflets are arranged along the midrib, as in rose leaves (*Rosa* sp.), or the leaves of hickory, pecan, ash, or walnut trees.

**Figure 23.23** Leaves may be simple or compound. In simple leaves, the lamina is continuous. The (a) banana plant (*Musa sp.*) has simple leaves. In compound leaves, the lamina is separated into leaflets. Compound leaves may be palmate or pinnate. In (b) palmately compound leaves, such as those of the horse chestnut (*Aesculus hippocastanum*), the leaflets branch from the petiole. In (c) pinnately compound leaves, the leaflets branch from the midrib, as on a scrub hickory (*Carya floridana*). The (d) honey locust has double compound leaves, in which leaflets branch from the veins. ## Leaf Structure and Function

The outermost layer of the leaf is the epidermis; it is present on both sides of the leaf and is called the upper and lower epidermis, respectively. Botanists call the upper side the adaxial surface (or adaxis) and the lower side the abaxial surface (or abaxis). The epidermis helps in the regulation of gas exchange. It contains stomata (Figure 23.24): openings through which the exchange of gases takes place. Two guard cells surround each stoma, regulating its opening and closing.

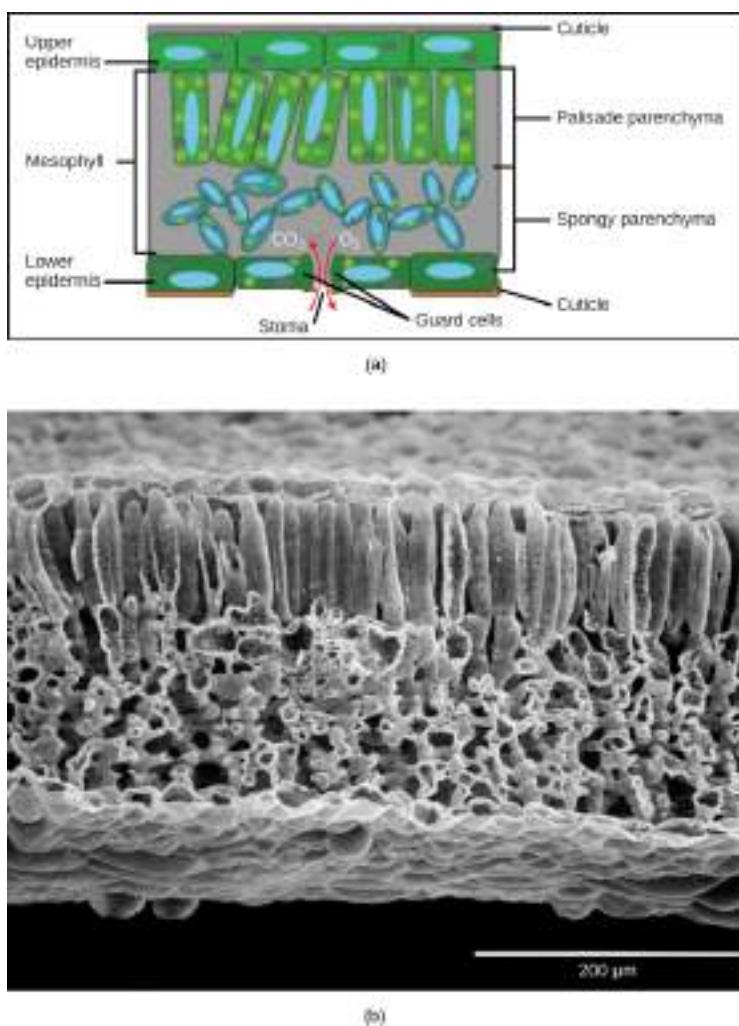

**Figure 23.24** Visualized at 500x with a scanning electron microscope, several stomata are clearly visible on (a) the surface of this sumac (*Rhus glabra*) leaf. At 5,000x magnification, the guard cells of (b) a single stoma from lyre-leaved sand cress (*Arabidopsis lyrata*) have the appearance of lips that surround the opening. In this (c) light micrograph cross-section of an *A. lyrata* leaf, the guard cell pair is visible along with the large, sub-stomatal air space in the leaf. (credit: modification of work by Robert R. Wise; part c scale-bar data from Matt Russell)

The epidermis is usually one cell layer thick; however, in plants that grow in very hot or very cold conditions, the epidermis may be several layers thick to protect against excessive water loss from transpiration. A waxy layer known as the cuticle covers the leaves of all plant species. The cuticle reduces the rate of water loss from the leaf surface. Other leaves may have small hairs (trichomes) on the leaf surface. Trichomes help to deter herbivory by restricting insect movements, or by storing toxic or bad-tasting compounds; they can also reduce the rate of transpiration by blocking air flow across the leaf surface (Figure 23.25).

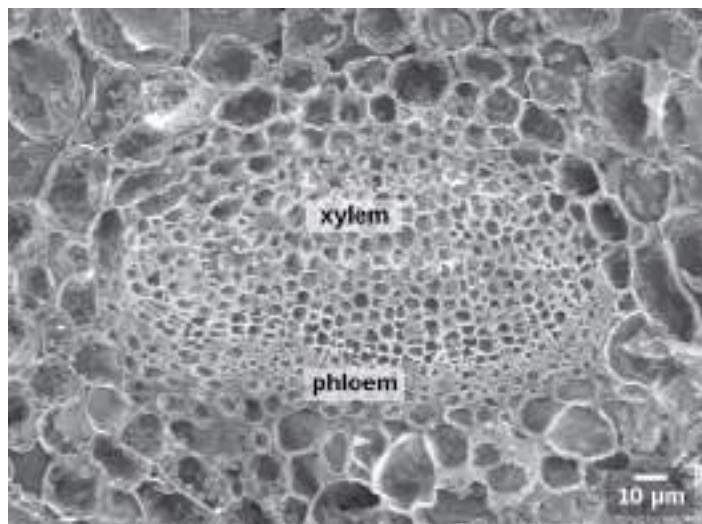

**Figure 23.25** Trichomes give leaves a fuzzy appearance as in this (a) sundew (*Drosera* sp.). Leaf trichomes include (b) branched trichomes on the leaf of *Arabidopsis lyrata* and (c) multibranched trichomes on a mature *Quercus marilandica* leaf. (credit a: John Freeland; credit b, c: modification of work by Robert R. Wise; scale-bar data from Matt Russell)

Below the epidermis of dicot leaves are layers of cells known as the mesophyll, or “middle leaf.” The mesophyll of most leaves typically contains two arrangements of parenchyma cells: the palisade parenchyma and spongy parenchyma (Figure 23.26). The palisade parenchyma (also called the palisade mesophyll) has column-shaped, tightly packed cells, and may be present in one, two, or three layers. Below the palisade parenchyma are loosely arranged cells of an irregular shape. These are the cells of the spongy parenchyma (or spongy mesophyll). The air space found between the spongy parenchyma cells allows gaseous exchange between the leaf and the outside atmosphere through the stomata. In aquatic plants, the intercellular spaces in the spongy parenchyma help the leaf float. Both layers of the mesophyll contain many chloroplasts. Guard cells are the only epidermal cells to contain chloroplasts.

**Figure 23.26** In the (a) leaf drawing, the central mesophyll is sandwiched between an upper and lower epidermis. The mesophyll has two layers: an upper palisade layer comprised of tightly packed, columnar cells, and a lower spongy layer, comprised of loosely packed, irregularly shaped cells. Stomata on the leaf underside allow gas exchange. A waxy cuticle covers all aerial surfaces of land plants to minimize water loss. These leaf layers are clearly visible in the (b) scanning electron micrograph. The numerous small bumps in the palisade parenchyma cells are chloroplasts. Chloroplasts are also present in the spongy parenchyma, but are not as obvious. The bumps protruding from the lower surface of the leave are glandular trichomes, which differ in structure from the stalked trichomes in [Figure 23.25](#). (credit b: modification of work by Robert R. Wise)

Like the stem, the leaf contains vascular bundles composed of xylem and phloem ([Figure 23.27](#)). The xylem consists of tracheids and vessels, which transport water and minerals to the leaves. The phloem transports the photosynthetic products from the leaf to the other parts of the plant. A single vascular bundle, no matter how large or small, always contains both xylem and phloem tissues.

**Figure 23.27** This scanning electron micrograph shows xylem and phloem in the leaf vascular bundle from the lyre-leaved sand cress (*Arabidopsis lyrata*). (credit: modification of work by Robert R. Wise; scale-bar data from Matt Russell)

## Leaf Adaptations

Coniferous plant species that thrive in cold environments, like spruce, fir, and pine, have leaves that are reduced in size and needle-like in appearance. These needle-like leaves have sunken stomata and a smaller surface area: two attributes that aid in reducing water loss. In hot climates, plants such as cacti have leaves that are reduced to spines, which in combination with their succulent stems, help to conserve water. Many aquatic plants have leaves with wide lamina that can float on the surface of the water, and a thick waxy cuticle on the leaf surface that repels water.

Watch “The Pale Pitcher Plant” episode of the [video \(\[http://openstaxcollege.org/l/plants\\\_cool\\\_too\]\(http://openstaxcollege.org/l/plants\_cool\_too\)\)](http://openstaxcollege.org/l/plants_cool_too) series *Plants Are Cool, Too*, a Botanical Society of America video about a carnivorous plant species found in Louisiana.

How do pale pitcher plants (*Sarracenia alata*) make sure that insects do not escape after consuming the nectar that attracted them?

- a. The insects are skewered on spikes and thorns that rim the funnel-shaped leaf.
- b. The insects ingest narcotics secreted by the leaf and fall into the funnel-shaped leaf.
- c. The insects are poisoned by lethal compounds in the nectar.
- d. The insects are immobilized by sticky substances on the rim of the funnel-shaped leaf.

## Plant Adaptations in Resource-Deficient Environments

Roots, stems, and leaves are structured to ensure that a plant can obtain the required sunlight, water, soil nutrients, and oxygen resources. Some remarkable adaptations have evolved to enable plant species to thrive in less than ideal habitats, where one or more of these resources is in short supply.

In tropical rainforests, light is often scarce, since many trees and plants grow close together and block much of the sunlight from reaching the forest floor. Many tropical plant species have exceptionally broad leaves to maximize the capture of sunlight. Other species are epiphytes: plants that grow on other plants that serve as a physical support. Such plants are able to grow high up in the canopy atop the branches of other trees, where sunlight is more plentiful. Epiphytes live on rain and minerals collected in the branches and leaves of the supporting plant. Bromeliads (members of the pineapple family), ferns, and orchids are examples of tropical epiphytes (Figure 23.28). Many epiphytes have specialized tissues that enable them to efficiently capture and store water.

**Figure 23.28** One of the most well known bromeliads is Spanish moss (*Tillandsia usneoides*), seen here in an oak tree. (credit: Kristine Paulus)

Some plants have special adaptations that help them to survive in nutrient-poor environments. Carnivorous plants, such as the Venus flytrap and the pitcher plant (Figure 23.29), grow in bogs where the soil is low in nitrogen. In these plants, leaves are modified to capture insects. The insect-capturing leaves may have evolved to provide these plants with a supplementary source of much-needed nitrogen.

**Figure 23.29** The (a) Venus flytrap has modified leaves that can capture insects. When an unlucky insect touches the trigger hairs inside the leaf, the trap suddenly closes. The opening of the (b) pitcher plant is lined with a slippery wax. Insects crawling on the lip slip and fall into a pool of water in the bottom of the pitcher, where they are digested by bacteria. The plant then absorbs the smaller molecules. (credit a: modification of work by Peter Shanks; credit b: modification of work by Tim Mansfield)

Many swamp plants have adaptations that enable them to thrive in wet areas, where their roots grow submerged underwater. In these aquatic areas, the soil is unstable and little oxygen is available to reach the roots. Trees such as mangroves (*Rhizophora* sp.) growing in coastal waters produce aboveground roots that help support the tree (Figure 23.30). Some species of mangroves, as well as cypress trees, have pneumatophores: upward-growing roots containing pores and pockets of tissue specialized for gas exchange. Wild rice is an aquatic plant with large air spaces in the root cortex. The air-filled tissue—called aerenchyma—provides a path for oxygen to diffuse down to the root tips, which are embedded in oxygen-poor bottom sediments.

How do pale pitcher plants (*Sarracenia alata*) make sure that insects do not escape after consuming the nectar that attracted them?

- The insects are skewered on spikes and thorns that rim the funnel-shaped leaf.
- The insects ingest narcotics secreted by the leaf and fall into the funnel-shaped leaf.
- The insects are poisoned by lethal compounds in the nectar.
- The insects are immobilized by sticky substances on the rim of the funnel-shaped leaf.

**Figure 23.30** The branches of (a) mangrove trees develop aerial roots, which descend to the ground and help to anchor the trees. (b) Cypress trees and some mangrove species have upward-growing roots called pneumatophores that are involved in gas exchange. Aquatic plants such as (c) wild rice have large spaces in the root cortex called aerenchyma, visualized here using scanning electron microscopy. Watch **Venus Flytraps: Jaws of Death** ([http://openstaxcollege.org/l/venus\\_flytrap](http://openstaxcollege.org/l/venus_flytrap)) , an extraordinary BBC close-up of the Venus flytrap in action.

Why do many ornamental plants that thrive indoors originate on the floor of tropical rainforest, where they grow under the canopy of trees?

- Growing under the rainforest's canopy made these plants adapt to less water and nutrients.
- With their narrow leaves, these plants are adapted to grow in low light.
- With their broad leaves, these plants are adapted to grow in low light, like that usually found indoors.
- Growing under the rainforest's canopy provides the plants with more water and nutrients, which they also need as indoor plants.

## 23.5 | Transport of Water and Solutes in Plants

In this section, you will explore the following questions:

- What is water potential, and how is it influenced by solutes, pressures, gravity, and the matric potential?
- How do water potential, evapotranspiration, and stomatal regulation influence how water is transported in plants?
- How are photosynthates transported in plants?

### Connection for AP<sup>®</sup> Courses

Information in this section applies to concepts we explored in previous chapters by connecting them to the transport of water and solutes through a plant, showing ways that plants take up and transport materials. These concepts include the processes of photosynthesis and cellular respiration, the chemical and physical properties of water, and the coevolution of plants with mutualistic bacteria and fungi. The vascular system of terrestrial plants allows the efficient absorption and delivery of water through the cells that comprise xylem, whereas phloem delivers sugars produced in photosynthesis to all parts of the plant, including the roots for storage. The physical separation of xylem and phloem permits plants to move different nutrients simultaneously from roots to shoots and vice versa. Nearly all plants use related mechanisms of osmoregulation, and we will focus on the transport of water and other nutrients.

You likely remember the concept of **water potential** ( $\Psi$ ) from our exploration of diffusion and osmosis in the chapter where we discuss the structure and function of plasma membranes. Water potential is a measure of the differences in potential energy between a water sample with solutes and pure water. Water moves via osmosis from an area of higher water potential (more water molecules, less solute) to an area of lower water potential (less water, more solutes). The water potential in plant solutions is influenced by solute concentration, pressure, gravity, and other factors (matrix effects). Water potential and transpiration influence how water is transported through the xylem.

Carbohydrates synthesized in photosynthesis, primarily sucrose, move from sources to sinks through the plant's phloem. Sucrose produced in the Calvin cycle is loaded into the sieve-tube elements of the phloem, and the increased solute concentration causes water to move by osmosis from the xylem into the phloem.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 and Big Idea 4 of the AP<sup>®</sup> Biology Curriculum Framework. The AP<sup>®</sup> Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP<sup>®</sup> Biology course, an inquiry-based laboratory experience, instructional activities, and

AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

The Practice Challenge Questions contain additional test questions for this section that will help you prepare for the AP exam. These questions address the following standards:

[APLO 2.40][APLO 4.12][APLO 2.1][APLO 2.8][APLO 2.9][APLO 2.41][APLO 1.2][APLO 1.22][APLO 1.25][APLO 2.19][APLO 2.32]

The structure of plant roots, stems, and leaves facilitates the transport of water, nutrients, and photosynthates throughout the plant. The phloem and xylem are the main tissues responsible for this movement. Water potential, evapotranspiration, and stomatal regulation influence how water and nutrients are transported in plants. To understand how these processes work, we must first understand the energetics of water potential.

## Water Potential

Plants are phenomenal hydraulic engineers. Using only the basic laws of physics and the simple manipulation of potential energy, plants can move water to the top of a 116-meter-tall tree (**Figure 23.31a**). Plants can also use hydraulics to generate enough force to split rocks and buckle sidewalks (**Figure 23.31b**). Plants achieve this because of water potential.

**Figure 23.31** With heights nearing 116 meters, (a) coastal redwoods (*Sequoia sempervirens*) are the tallest trees in the world. Plant roots can easily generate enough force to (b) buckle and break concrete sidewalks, much to the dismay of homeowners and city maintenance departments. (credit a: modification of work by Bernt Rostad; credit b: modification of work by Pedestrians Educating Drivers on Safety, Inc.)

Water potential is a measure of the potential energy in water. Plant physiologists are not interested in the energy in any one particular aqueous system, but are very interested in water movement between two systems. In practical terms, therefore, water potential is the difference in potential energy between a given water sample and pure water (at atmospheric pressure and ambient temperature). Water potential is denoted by the Greek letter  $\Psi$  (*psi*) and is expressed in units of pressure (pressure is a form of energy) called **megapascals** (MPa). The potential of pure water ( $\Psi_w^{\text{pure H}_2\text{O}}$ ) is, by convenience of definition, designated a value of zero (even though pure water contains plenty of potential energy, that energy is ignored). Water potential values for the water in a plant root, stem, or leaf are therefore expressed relative to  $\Psi_w^{\text{pure H}_2\text{O}}$ .

The water potential in plant solutions is influenced by solute concentration, pressure, gravity, and factors called matrix effects. Water potential can be broken down into its individual components using the following equation:

$$\Psi_{\text{system}} = \Psi_{\text{total}} = \Psi_s + \Psi_p + \Psi_g + \Psi_m$$

where  $\Psi_s$ ,  $\Psi_p$ ,  $\Psi_g$ , and  $\Psi_m$  refer to the solute, pressure, gravity, and matric potentials, respectively. “System” can refer to the water potential of the soil water ( $\Psi^{\text{soil}}$ ), root water ( $\Psi^{\text{root}}$ ), stem water ( $\Psi^{\text{stem}}$ ), leaf water ( $\Psi^{\text{leaf}}$ ) or the water in the atmosphere ( $\Psi^{\text{atmosphere}}$ ): whichever aqueous system is under consideration. As the individual components change, they raise or lower the total water potential of a system. When this happens, water moves to equilibrate, moving from the system or compartment with a higher water potential to the system or compartment with a lower water potential. This brings the difference in water potential between the two systems ( $\Delta\Psi$ ) back to zero ( $\Delta\Psi = 0$ ). Therefore, for water to move through the plant from the soil to the air (a process called transpiration),  $\Psi^{\text{soil}}$  must be  $> \Psi^{\text{root}} > \Psi^{\text{stem}} > \Psi^{\text{leaf}} > \Psi^{\text{atmosphere}}$ .

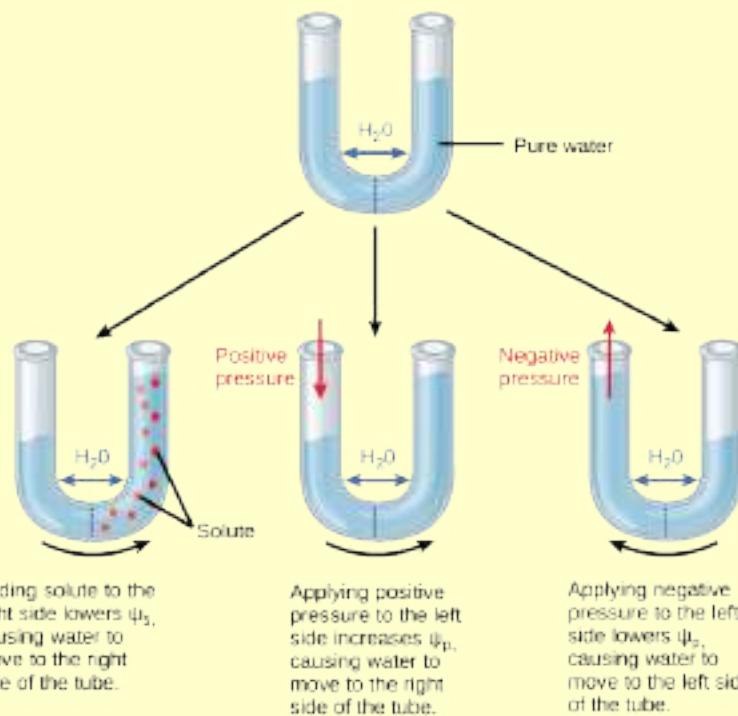

Water only moves in response to  $\Delta\Psi$ , not in response to the individual components. However, because the individual components influence the total  $\Psi_{\text{system}}$ , by manipulating the individual components (especially  $\Psi_s$ ), a plant can control water movement.

### Solute Potential

Solute potential ( $\Psi_s$ ), also called osmotic potential, is negative in a plant cell and zero in distilled water. Typical values for cell cytoplasm are  $-0.5$  to  $-1.0$  MPa. Solutes reduce water potential (resulting in a negative  $\Psi_w$ ) by consuming some of the potential energy available in the water. Solute molecules can dissolve in water because water molecules can bind to them via hydrogen bonds; a hydrophobic molecule like oil, which cannot bind to water, cannot go into solution. The energy in the hydrogen bonds between solute molecules and water is no longer available to do work in the system because it is tied up in the bond. In other words, the amount of available potential energy is reduced when solutes are added to an aqueous system. Thus,  $\Psi_s$  decreases with increasing solute concentration. Because  $\Psi_s$  is one of the four components of  $\Psi_{\text{system}}$  or  $\Psi_{\text{total}}$ , a decrease in  $\Psi_s$  will cause a decrease in  $\Psi_{\text{total}}$ . The internal water potential of a plant cell is more negative than pure water because of the cytoplasm’s high solute content (Figure 23.32). Because of this difference in water potential water will move from the soil into a plant’s root cells via the process of osmosis. This is why solute potential is sometimes called osmotic potential.

Plant cells can metabolically manipulate  $\Psi_s$  (and by extension,  $\Psi_{\text{total}}$ ) by adding or removing solute molecules. Therefore, plants have control over  $\Psi_{\text{total}}$  via their ability to exert metabolic control over  $\Psi_s$ .

## visual CONNECTION

**Figure 23.32** In this example with a semipermeable membrane between two aqueous systems, water will move from a region of higher to lower water potential until equilibrium is reached. Solutes ( $\psi_s$ ), pressure ( $\psi_p$ ), and gravity ( $\psi_g$ ) influence total water potential for each side of the tube ( $\psi_{\text{total}}^{\text{right or left}}$ ), and therefore, the difference between  $\psi_{\text{total}}$  on each side ( $\Delta\psi$ ). ( $\psi_m$ , the potential due to interaction of water with solid substrates, is ignored in this example because glass is not especially hydrophilic). Water moves in response to the difference in water potential between two systems (the left and right sides of the tube).

Positive water potential is applied on the left side of a tube by increasing  $\psi_p$  so that the water level rises on the right side. The equation for water potential is:  $\psi_{\text{system}} = \psi_{\text{total}} = \psi_s + \psi_p + \psi_g + \psi_m$  where  $\psi_s$ ,  $\psi_p$ ,  $\psi_g$ , and  $\psi_m$  refer to the solute, pressure, gravity, and matric potentials, respectively. Could you equalize the water level on each side of the tube by adding solute?

- Yes, water level can be equalized by adding solute to the right side of the tube so that water moves toward the left until the water levels are equal.
- No, water level cannot be equalized on both sides of the tubes by adding solutes with no other action.
- Yes, water level can be equalized by adding solute to the left side of the tube so that water moves toward the left until the water levels are equal.
- No, water level cannot be equalized by adding solutes because solutes are always pulled down by gravity, thereby not letting water equalize.

### Pressure Potential

Pressure potential ( $\psi_p$ ), also called turgor potential, may be positive or negative (Figure 23.32). Because pressure is an expression of energy, the higher the pressure, the more potential energy in a system, and vice versa. Therefore, a positive  $\psi_p$  (compression) increases  $\psi_{\text{total}}$ , and a negative  $\psi_p$  (tension) decreases  $\psi_{\text{total}}$ . Positive pressure inside cells is contained by the cell wall, producing turgor pressure. Pressure potentials are typically around 0.6–0.8 MPa, but can reach as high as 1.5 MPa in a well-watered plant. A  $\psi_p$  of 1.5 MPa equates to 210 pounds per square inch ( $1.5 \text{ MPa} \times 140 \text{ lb in}^{-2} \text{ MPa}^{-1} = 210 \text{ lb/in}^{-2}$ ). As a comparison, most automobile tires are kept at a pressure of 30–34 psi. An example of the effect of turgor pressure is the wilting of leaves and their restoration after the plant has been watered (Figure 23.33). Water is lost from the

leaves via transpiration (approaching  $\Psi_p = 0$  MPa at the wilting point) and restored by uptake via the roots.

A plant can manipulate  $\Psi_p$  via its ability to manipulate  $\Psi_s$  and by the process of osmosis. If a plant cell increases the cytoplasmic solute concentration,  $\Psi_s$  will decline,  $\Psi_{\text{total}}$  will decline, the  $\Delta\Psi$  between the cell and the surrounding tissue will decline, water will move into the cell by osmosis, and  $\Psi_p$  will increase.  $\Psi_p$  is also under indirect plant control via the opening and closing of stomata. Stomatal openings allow water to evaporate from the leaf, reducing  $\Psi_p$  and  $\Psi_{\text{total}}$  of the leaf and increasing  $\Delta\Psi$  between the water in the leaf and the petiole, thereby allowing water to flow from the petiole into the leaf.

**Figure 23.33** When (a) total water potential ( $\Psi_{\text{total}}$ ) is lower outside the cells than inside, water moves out of the cells and the plant wilts. When (b) the total water potential is higher outside the plant cells than inside, water moves into the cells, resulting in turgor pressure ( $\Psi_p$ ) and keeping the plant erect. (credit: modification of work by Victor M. Vicente Selvas)

### Gravity Potential

Gravity potential ( $\Psi_g$ ) is always negative to zero in a plant with no height. It always removes or consumes potential energy from the system. The force of gravity pulls water downwards to the soil, reducing the total amount of potential energy in the water in the plant ( $\Psi_{\text{total}}$ ). The taller the plant, the taller the water column, and the more influential  $\Psi_g$  becomes. On a cellular scale and in short plants, this effect is negligible and easily ignored. However, over the height of a tall tree like a giant coastal redwood, the gravitational pull of  $-0.1$  MPa  $\text{m}^{-1}$  is equivalent to an extra 1 MPa of resistance that must be overcome for water to reach the leaves of the tallest trees. Plants are unable to manipulate  $\Psi_g$ .

### Matric Potential

Matric potential ( $\Psi_m$ ) is always negative to zero. In a dry system, it can be as low as  $-2$  MPa in a dry seed, and it is zero in a water-saturated system. The binding of water to a matrix always removes or consumes potential energy from the system.  $\Psi_m$  is similar to solute potential because it involves tying up the energy in an aqueous system by forming hydrogen bonds between the water and some other component. However, in solute potential, the other components are soluble, hydrophilic solute molecules, whereas in  $\Psi_m$ , the other components are insoluble, hydrophilic molecules of the plant cell wall. Every plant cell has a cellulosic cell wall and the cellulose in the cell walls is hydrophilic, producing a matrix for adhesion of water: hence the name matric potential.  $\Psi_m$  is very large (negative) in dry tissues such as seeds or drought-affected soils. However, it quickly goes to zero as the seed takes up water or the soil hydrates.  $\Psi_m$  cannot be manipulated by the plant and is typically ignored in well-watered roots, stems, and leaves.

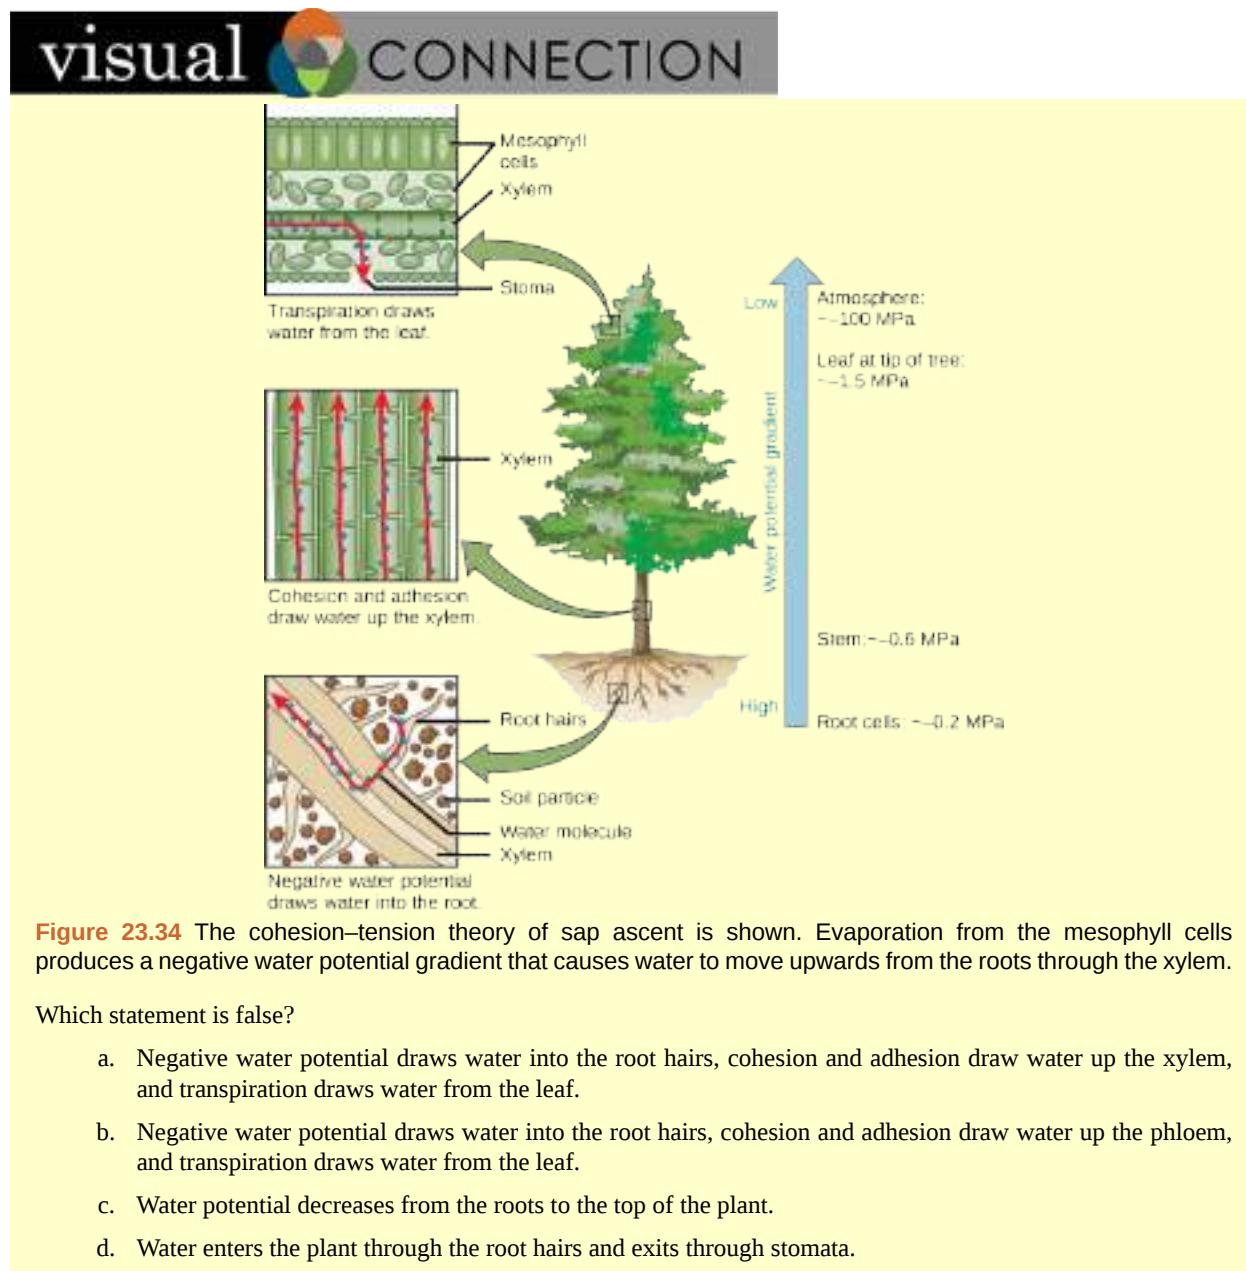

## Movement of Water and Minerals in the Xylem

Solutes, pressure, gravity, and matric potential are all important for the transport of water in plants. Water moves from an area of higher total water potential (higher Gibbs free energy) to an area of lower total water potential. Gibbs free energy is the energy associated with a chemical reaction that can be used to do work. This is expressed as  $\Delta\Psi$ .

**Transpiration** is the loss of water from the plant through evaporation at the leaf surface. It is the main driver of water movement in the xylem. Transpiration is caused by the evaporation of water at the leaf–atmosphere interface; it creates negative pressure (tension) equivalent to  $-2$  MPa at the leaf surface. This value varies greatly depending on the vapor pressure deficit, which can be negligible at high relative humidity (RH) and substantial at low RH. Water from the roots is pulled up by this tension. At night, when stomata shut and transpiration stops, the water is held in the stem and leaf by the adhesion of water to the cell walls of the xylem vessels and tracheids, and the cohesion of water molecules to each other. This is called the cohesion–tension theory of sap ascent.

Inside the leaf at the cellular level, water on the surface of mesophyll cells saturates the cellulose microfibrils of the primary cell wall. The leaf contains many large intercellular air spaces for the exchange of oxygen for carbon dioxide, which is

required for photosynthesis. The wet cell wall is exposed to this leaf internal air space, and the water on the surface of the cells evaporates into the air spaces, decreasing the thin film on the surface of the mesophyll cells. This decrease creates a greater tension on the water in the mesophyll cells (**Figure 23.34**), thereby increasing the pull on the water in the xylem vessels. The xylem vessels and tracheids are structurally adapted to cope with large changes in pressure. Rings in the vessels maintain their tubular shape, much like the rings on a vacuum cleaner hose keep the hose open while it is under pressure. Small perforations between vessel elements reduce the number and size of gas bubbles that can form via a process called cavitation. The formation of gas bubbles in xylem interrupts the continuous stream of water from the base to the top of the plant, causing a break termed an embolism in the flow of xylem sap. The taller the tree, the greater the tension forces needed to pull water, and the more cavitation events. In larger trees, the resulting embolisms can plug xylem vessels, making them non-functional.

**Figure 23.34** The cohesion–tension theory of sap ascent is shown. Evaporation from the mesophyll cells produces a negative water potential gradient that causes water to move upwards from the roots through the xylem.

Which statement is false?

- Negative water potential draws water into the root hairs, cohesion and adhesion draw water up the xylem, and transpiration draws water from the leaf.
- Negative water potential draws water into the root hairs, cohesion and adhesion draw water up the phloem, and transpiration draws water from the leaf.
- Water potential decreases from the roots to the top of the plant.
- Water enters the plant through the root hairs and exits through stomata.

**Transpiration**—the loss of water vapor to the atmosphere through stomata—is a passive process, meaning that metabolic energy in the form of ATP is not required for water movement. The energy driving transpiration is the difference in energy between the water in the soil and the water in the atmosphere. However, transpiration is tightly controlled.

### Control of Transpiration

The atmosphere to which the leaf is exposed drives transpiration, but also causes massive water loss from the plant. Up to 90 percent of the water taken up by roots may be lost through transpiration.

Leaves are covered by a waxy **cuticle** on the outer surface that prevents the loss of water. Regulation of transpiration, therefore, is achieved primarily through the opening and closing of stomata on the leaf surface. Stomata are surrounded by two specialized cells called guard cells, which open and close in response to environmental cues such as light intensity and quality, leaf water status, and carbon dioxide concentrations. Stomata must open to allow air containing carbon dioxide and oxygen to diffuse into the leaf for photosynthesis and respiration. When stomata are open, however, water vapor is lost to the external environment, increasing the rate of transpiration. Therefore, plants must maintain a balance between efficient photosynthesis and water loss.

Plants have evolved over time to adapt to their local environment and reduce transpiration (Figure 23.35). Desert plants (xerophytes) and plants that grow on other plants (epiphytes) have limited access to water. Such plants usually have a much thicker waxy cuticle than those growing in more moderate, well-watered environments (mesophytes). Aquatic plants (hydrophytes) also have their own set of anatomical and morphological leaf adaptations.

**Figure 23.35** Plants are suited to their local environment. (a) Xerophytes, like this prickly pear cactus (*Opuntia* sp.) and (b) epiphytes such as this tropical *Aeschynanthus perrottetii* have adapted to very limited water resources. The leaves of a prickly pear are modified into spines, which lowers the surface-to-volume ratio and reduces water loss. Photosynthesis takes place in the stem, which also stores water. (b) *A. perrottetii* leaves have a waxy cuticle that prevents water loss. (c) Goldenrod (*Solidago* sp.) is a mesophyte, well suited for moderate environments. (d) Hydrophytes, like this fragrant water lily (*Nymphaea odorata*), are adapted to thrive in aquatic environments. (credit a: modification of work by Jon Sullivan; credit b: modification of work by L. Shyamal/Wikimedia Commons; credit c: modification of work by Huw Williams; credit d: modification of work by Jason Hollinger)

Xerophytes and epiphytes often have a thick covering of trichomes or of stomata that are sunken below the leaf's surface. Trichomes are specialized hair-like epidermal cells that secrete oils and substances. These adaptations impede air flow across the stomatal pore and reduce transpiration. Multiple epidermal layers are also commonly found in these types of plants.

## Transportation of Photosynthates in the Phloem

Plants need an energy source to grow. In seeds and bulbs, food is stored in polymers (such as starch) that are converted by metabolic processes into sucrose for newly developing plants. Once green shoots and leaves are growing, plants are able to produce their own food by photosynthesizing. The products of photosynthesis are called photosynthates, which are usually in the form of simple sugars such as sucrose.

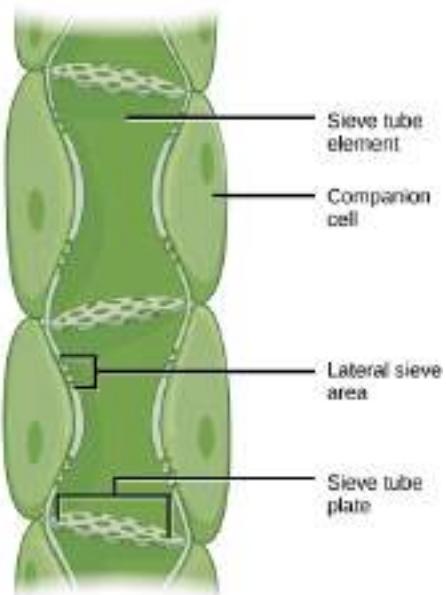

Structures that produce photosynthates for the growing plant are referred to as **sources**. Sugars produced in sources, such as leaves, need to be delivered to growing parts of the plant via the phloem in a process called **translocation**. The points of sugar delivery, such as roots, young shoots, and developing seeds, are called **sinks**. Seeds, tubers, and bulbs can be either a source or a sink, depending on the plant's stage of development and the season.

The products from the source are usually translocated to the nearest sink through the phloem. For example, the highest leaves will send photosynthates upward to the growing shoot tip, whereas lower leaves will direct photosynthates downward to the roots. Intermediate leaves will send products in both directions, unlike the flow in the xylem, which is always unidirectional (soil to leaf to atmosphere). The pattern of photosynthetic flow changes as the plant grows and develops. Photosynthates are directed primarily to the roots early on, to shoots and leaves during vegetative growth, and to seeds and fruits during reproductive development. They are also directed to tubers for storage.

### **Translocation: Transport from Source to Sink**

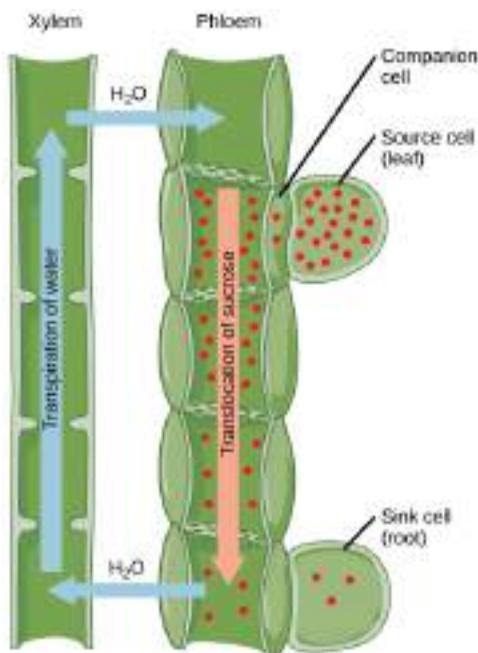

Photosynthates, such as sucrose, are produced in the mesophyll cells of photosynthesizing leaves. From there they are translocated through the phloem to where they are used or stored. Mesophyll cells are connected by cytoplasmic channels called plasmodesmata. Photosynthates move through these channels to reach phloem sieve-tube elements (STEs) in the vascular bundles. From the mesophyll cells, the photosynthates are loaded into the phloem STEs. The sucrose is actively transported against its concentration gradient (a process requiring ATP) into the phloem cells using the electrochemical potential of the proton gradient. This is coupled to the uptake of sucrose with a carrier protein called the sucrose-H<sup>+</sup> symporter.

Phloem STEs have reduced cytoplasmic contents, and are connected by a sieve plate with pores that allow for pressure-driven bulk flow, or translocation, of phloem sap. Companion cells are associated with STEs. They assist with metabolic activities and produce energy for the STEs (**Figure 23.36**).

**Figure 23.36** Phloem is comprised of cells called sieve-tube elements. Phloem sap travels through perforations called sieve tube plates. Neighboring companion cells carry out metabolic functions for the sieve-tube elements and provide them with energy. Lateral sieve areas connect the sieve-tube elements to the companion cells.

Once in the phloem, the photosynthates are translocated to the closest sink. Phloem sap is an aqueous solution that contains up to 30 percent sugar, minerals, amino acids, and plant growth regulators. The high percentage of sugar decreases  $\Psi_s$ , which decreases the total water potential and causes water to move by osmosis from the adjacent xylem into the phloem tubes, thereby increasing pressure. This increase in total water potential causes the bulk flow of phloem from source to sink (Figure 23.37). Sucrose concentration in the sink cells is lower than in the phloem STEs because the sink sucrose has been metabolized for growth, or converted to starch for storage or other polymers, such as cellulose, for structural integrity. Unloading at the sink end of the phloem tube occurs by either diffusion or active transport of sucrose molecules from an area of high concentration to one of low concentration. Water diffuses from the phloem by osmosis and is then transpired or recycled via the xylem back into the phloem sap.

**Figure 23.37** Sucrose is actively transported from source cells into companion cells and then into the sieve-tube elements. This reduces the water potential, which causes water to enter the phloem from the xylem. The resulting positive pressure forces the sucrose-water mixture down toward the roots, where sucrose is unloaded. Transpiration causes water to return to the leaves through the xylem vessels.

## science practices CONNECTION for AP® Courses

### Activity

Based on water's molecular properties, create a visual diagram/model to illustrate how water travels up a 300-foot California redwood tree through xylem.

### Lab Investigation

*AP® Biology Investigative Labs: Inquiry-Based, Investigation 11: Transpiration.* Design and conduct a series of experiments to investigate the effects of environmental variables on transpiration rates.

### Think About It

Desert travelers claim that cactus juice tastes sweeter during the day than at night. Based on your understanding of photosynthesis, transpiration, and the regulation of stomata by guard cells in response to environmental conditions, is there any validity to this claim?

## 23.6 | Plant Sensory Systems and Responses

In this section, you will explore the following questions:

- How do red and blue light affect plant growth and metabolic activities?
- What is gravitropism?
- What are examples of plant hormones, and how do they affect plant growth and development?
- What are the differences between thigmotropism, thigmonastism, and thigmogenesis?
- How do plants defend themselves against predators and respond to wounds?

### Connection for AP® Courses

Why do some flowering plants bloom in the spring, whereas others bloom in the summer or fall? Why do the stems of plants grow upward and bend toward light, while roots grow downward? Why do the leaves of deciduous plants in northern climates turn colors in the fall and eventually fall off, while evergreens keep their needles all year around? Is it true that putting an unripe avocado in a paper bag will hasten the ripening process? Can the same tactic work on bananas?

Like most other organisms, plants have the ability to detect and respond to environmental change; this ability is an adaptation favored by natural selection. Flowering plants react to light, gravity, infection by pathogens, drought, and, as with the Venus flytrap, touch. Animals have two systems on which they can rely to detect and respond to stimuli: the nervous and endocrine systems. Plants, however, only have chemical control mechanisms at their disposal. In addition to the phytochromes, plants evolved hormones that allow them to respond to environmental changes. Like animal hormones, plant hormones are chemical signaling molecules that trigger a cellular response through a signal transduction pathway.

Although you do not have to memorize a laundry list of plant hormones and their activities, you should understand the basic mechanism of how they trigger a response. Examples that we'll learn about in this chapter include auxins, which cause plant stems to grow and bend toward light, and gibberellins, which stimulate cell growth and breaks seed dormancy. Plants also produce other chemicals to protect against biotic stimuli, including herbivory and parasitism. The fact that plants produce chemicals should not be surprising; our pharmaceutical industry depends on these substances. For example, species of the foxglove plant produce digitalis, a powerful heart medicine, whereas the opium from the poppy is the source of many narcotics.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 and Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>2.40</b> The student is able to connect concepts in and across domain(s) to predict how environmental factors affect responses to information and change behavior.                        |
| <b>Big Idea 3</b>                 | Living systems store, retrieve, transmit and respond to information essential to life processes.                                                                                             |
| <b>Enduring Understanding 3.B</b> | Expression of genetic information involves cellular and molecular mechanisms.                                                                                                                |
| <b>Essential Knowledge</b>        | <b>3.B.2</b> Signal transmission within and between plant cells mediates gene expression.                                                                                                    |
| <b>Science Practice</b>           | 6.2 The student can construct explanations of phenomena based on evidence produced through scientific practices.                                                                             |
| <b>Learning Objective</b>         | <b>3.22</b> The student is able to explain how signal pathways mediate gene expression, including how this process can affect protein production.                                            |

The Science Practice Challenge Questions contain additional test questions for this section that will help you prepare for

the AP exam. These questions address the following standards:

[APLO 2.29][APLO 2.30]

Animals can respond to environmental factors by moving to a new location. Plants, however, are rooted in place and must respond to the surrounding environmental factors. Plants have sophisticated systems to detect and respond to light, gravity, temperature, and physical touch. Receptors sense environmental factors and relay the information to effector systems—often through intermediate chemical messengers—to bring about plant responses.

## Plant Responses to Light

Plants have a number of sophisticated uses for light that go far beyond their ability to photosynthesize low-molecular-weight sugars using only carbon dioxide, light, and water. **Photomorphogenesis** is the growth and development of plants in response to light. It allows plants to optimize their use of light and space. **Photoperiodism** is the ability to use light to track time. Plants can tell the time of day and time of year by sensing and using various wavelengths of sunlight. **Phototropism** is a directional response that allows plants to grow towards, or even away from, light.

The sensing of light in the environment is important to plants; it can be crucial for competition and survival. The response of plants to light is mediated by different photoreceptors, which are comprised of a protein covalently bonded to a light-absorbing pigment called a **chromophore**. Together, the two are called a chromoprotein.

The red/far-red and violet-blue regions of the visible light spectrum trigger structural development in plants. Sensory photoreceptors absorb light in these particular regions of the visible light spectrum because of the quality of light available in the daylight spectrum. In terrestrial habitats, light absorption by chlorophylls peaks in the blue and red regions of the spectrum. As light filters through the canopy and the blue and red wavelengths are absorbed, the spectrum shifts to the far-red end, shifting the plant community to those plants better adapted to respond to far-red light. Blue-light receptors allow plants to gauge the direction and abundance of sunlight, which is rich in blue-green emissions. Water absorbs red light, which makes the detection of blue light essential for algae and aquatic plants.

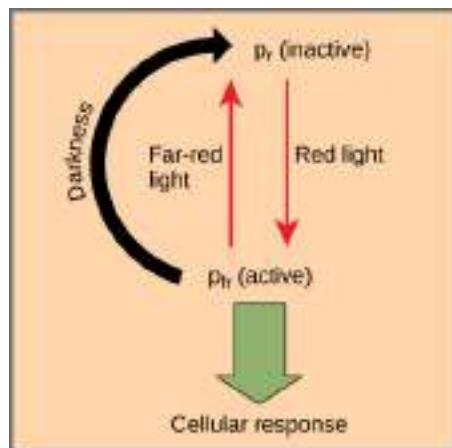

### **The Phytochrome System and the Red/Far-Red Response**

The **phytochromes** are a family of chromoproteins with a linear tetrapyrrole chromophore, similar to the ringed tetrapyrrole light-absorbing head group of chlorophyll. Phytochromes have two photo-interconvertible forms: Pr and Pfr. Pr absorbs red light (~667 nm) and is immediately converted to Pfr. Pfr absorbs far-red light (~730 nm) and is quickly converted back to Pr. Absorption of red or far-red light causes a massive change to the shape of the chromophore, altering the conformation and activity of the phytochrome protein to which it is bound. Pfr is the physiologically active form of the protein; therefore, exposure to red light yields physiological activity. Exposure to far-red light inhibits phytochrome activity. Together, the two forms represent the phytochrome system (**Figure 23.38**).

The phytochrome system acts as a biological light switch. It monitors the level, intensity, duration, and color of environmental light. The effect of red light is reversible by immediately shining far-red light on the sample, which converts the chromoprotein to the inactive Pr form. Additionally, Pfr can slowly revert to Pr in the dark, or break down over time. In all instances, the physiological response induced by red light is reversed. The active form of phytochrome (Pfr) can directly activate other molecules in the cytoplasm, or it can be trafficked to the nucleus, where it directly activates or represses specific gene expression.

Once the phytochrome system evolved, plants adapted it to serve a variety of needs. Unfiltered, full sunlight contains much more red light than far-red light. Because chlorophyll absorbs strongly in the red region of the visible spectrum, but not in the far-red region, any plant in the shade of another plant on the forest floor will be exposed to red-depleted, far-red-enriched light. The preponderance of far-red light converts phytochrome in the shaded leaves to the Pr (inactive) form, slowing growth. The nearest non-shaded (or even less-shaded) areas on the forest floor have more red light; leaves exposed to these areas sense the red light, which activates the Pfr form and induces growth. In short, plant shoots use the phytochrome system to grow away from shade and towards light. Because competition for light is so fierce in a dense plant community, the evolutionary advantages of the phytochrome system are obvious.

In seeds, the phytochrome system is not used to determine direction and quality of light (shaded versus unshaded). Instead, it is used merely to determine if there is any light at all. This is especially important in species with very small seeds, such as lettuce. Because of their size, lettuce seeds have few food reserves. Their seedlings cannot grow for long before they run out of fuel. If they germinated even a centimeter under the soil surface, the seedling would never make it into the sunlight and would die. In the dark, phytochrome is in the Pr (inactive form) and the seed will not germinate; it will only germinate if exposed to light at the surface of the soil. Upon exposure to light, Pr is converted to Pfr and germination proceeds.

**Figure 23.38** The biologically inactive form of phytochrome ( $P_r$ ) is converted to the biologically active form  $Pfr$  under illumination with red light. Far-red light and darkness convert the molecule back to the inactive form.

Plants also use the phytochrome system to sense the change of season. Photoperiodism is a biological response to the timing and duration of day and night. It controls flowering, setting of winter buds, and vegetative growth. Detection of seasonal changes is crucial to plant survival. Although temperature and light intensity influence plant growth, they are not reliable indicators of season because they may vary from one year to the next. Day length is a better indicator of the time of year.

As stated above, unfiltered sunlight is rich in red light but deficient in far-red light. Therefore, at dawn, all the phytochrome molecules in a leaf quickly convert to the active  $Pfr$  form, and remain in that form until sunset. In the dark, the  $Pfr$  form takes hours to slowly revert back to the  $P_r$  form. If the night is long (as in winter), all of the  $Pfr$  form reverts. If the night is short (as in summer), a considerable amount of  $Pfr$  may remain at sunrise. By sensing the  $P_r/Pfr$  ratio at dawn, a plant can determine the length of the day/night cycle. In addition, leaves retain that information for several days, allowing a comparison between the length of the previous night and the preceding several nights. Shorter nights indicate springtime to the plant; when the nights become longer, autumn is approaching. This information, along with sensing temperature and water availability, allows plants to determine the time of the year and adjust their physiology accordingly. Short-day (long-night) plants use this information to flower in the late summer and early fall, when nights exceed a critical length (often eight or fewer hours). Long-day (short-night) plants flower during the spring, when darkness is less than a critical length (often eight to 15 hours). Not all plants use the phytochrome system in this way. Flowering in day-neutral plants is not regulated by daylength.

 **Career CONNECTION**

## Horticulturist

The word “horticulturist” comes from the Latin words for garden (*hortus*) and culture (*cultura*). This career has been revolutionized by progress made in the understanding of plant responses to environmental stimuli. Growers of crops, fruit, vegetables, and flowers were previously constrained by having to time their sowing and harvesting according to the season. Now, horticulturists can manipulate plants to increase leaf, flower, or fruit production by understanding how environmental factors affect plant growth and development.

Greenhouse management is an essential component of a horticulturist’s education. To lengthen the night, plants are covered with a blackout shade cloth. Long-day plants are irradiated with red light in winter to promote early flowering. For example, fluorescent (cool white) light high in blue wavelengths encourages leafy growth and is excellent for starting seedlings. Incandescent lamps (standard light bulbs) are rich in red light, and promote flowering in some plants. The timing of fruit ripening can be increased or delayed by applying plant hormones. Recently, considerable progress has been made in the development of plant breeds that are suited to different climates and resistant to pests and transportation damage. Both crop yield and quality have increased as a result of practical applications of the knowledge of plant responses to external stimuli and hormones.

Horticulturists find employment in private and governmental laboratories, greenhouses, botanical gardens, and in the production or research fields. They improve crops by applying their knowledge of genetics and plant physiology. To prepare for a horticulture career, students take classes in botany, plant physiology, plant pathology, landscape design, and plant breeding. To complement these traditional courses, horticulture majors add studies in economics, business, computer science, and communications.

### ***The Blue Light Responses***

Phototropism—the directional bending of a plant toward or away from a light source—is a response to blue wavelengths of light. Positive phototropism is growth towards a light source (Figure 23.39), while negative phototropism (also called skototropism) is growth away from light.

The aptly-named **phototropins** are protein-based receptors responsible for mediating the phototropic response. Like all plant photoreceptors, phototropins consist of a protein portion and a light-absorbing portion, called the chromophore. In phototropins, the chromophore is a covalently-bound molecule of flavin; hence, phototropins belong to a class of proteins called flavoproteins.

Other responses under the control of phototropins are leaf opening and closing, chloroplast movement, and the opening of stomata. However, of all responses controlled by phototropins, phototropism has been studied the longest and is the best understood.

In their 1880 treatise *The Power of Movements in Plants*, Charles Darwin and his son Francis first described phototropism as the bending of seedlings toward light. Darwin observed that light was perceived by the tip of the plant (the apical meristem), but that the response (bending) took place in a different part of the plant. They concluded that the signal had to travel from the apical meristem to the base of the plant.

**Figure 23.39** Azure bluet (*Houstonia caerulea*) display a phototropic response by bending toward the light. (credit: Cory Zanker)

In 1913, Peter Boysen-Jensen demonstrated that a chemical signal produced in the plant tip was responsible for the bending at the base. He cut off the tip of a seedling, covered the cut section with a layer of gelatin, and then replaced the tip. The seedling bent toward the light when illuminated. However, when impermeable mica flakes were inserted between the tip and the cut base, the seedling did not bend. A refinement of the experiment showed that the signal traveled on the shaded side of the seedling. When the mica plate was inserted on the illuminated side, the plant did bend towards the light. Therefore, the chemical signal was a growth stimulant because the phototropic response involved faster cell elongation on the shaded side than on the illuminated side. We now know that as light passes through a plant stem, it is diffracted and generates phototropin activation across the stem. Most activation occurs on the lit side, causing the plant hormone indole acetic acid (IAA) to accumulate on the shaded side. Stem cells elongate under influence of IAA.

**Cryptochromes** are another class of blue-light absorbing photoreceptors that also contain a flavin-based chromophore. Cryptochromes set the plants 24-hour activity cycle, also known as its circadian rhythm, using blue light cues. There is some evidence that cryptochromes work together with phototropins to mediate the phototropic response.

If green light was used rather than white light to irradiate a sunflower seedling, what would happen?

- Green light is absorbed by the plant. The seedling would not bend, but it would grow tall and spindly as if grown in the dark.
- Green light is not absorbed by the plant. The seedling would not bend, but it would grow tall and spindly as if grown in the dark.
- Green light is not absorbed by the plant. The seedling would not grow tall and spindly, but it would bend.
- Green light is absorbed by the plant. The seedling would not grow tall and spindly, but it would bend.

## Plant Responses to Gravity

Whether or not they germinate in the light or in total darkness, shoots usually sprout up from the ground, and roots

grow downward into the ground. A plant laid on its side in the dark will send shoots upward when given enough time. Gravitropism ensures that roots grow into the soil and that shoots grow toward sunlight. Growth of the shoot apical tip upward is called **negative gravitropism**, whereas growth of the roots downward is called **positive gravitropism**.

**Amyloplasts** (also known as **statoliths**) are specialized plastids that contain starch granules and settle downward in response to gravity. Amyloplasts are found in shoots and in specialized cells of the root cap. When a plant is tilted, the statoliths drop to the new bottom cell wall. A few hours later, the shoot or root will show growth in the new vertical direction.

The mechanism that mediates gravitropism is reasonably well understood. When amyloplasts settle to the bottom of the gravity-sensing cells in the root or shoot, they physically contact the endoplasmic reticulum (ER), causing the release of calcium ions from inside the ER. This calcium signaling in the cells causes polar transport of the plant hormone IAA to the bottom of the cell. In roots, a high concentration of IAA inhibits cell elongation. The effect slows growth on the lower side of the root, while cells develop normally on the upper side. IAA has the opposite effect in shoots, where a higher concentration at the lower side of the shoot stimulates cell expansion, causing the shoot to grow up. After the shoot or root begin to grow vertically, the amyloplasts return to their normal position. Other hypotheses—Involving the entire cell in the gravitropism effect—have been proposed to explain why some mutants that lack amyloplasts may still exhibit a weak gravitropic response.

## Growth Responses

A plant's sensory response to external stimuli relies on chemical messengers (hormones). Plant hormones affect all aspects of plant life, from flowering to fruit setting and maturation, and from phototropism to leaf fall. Potentially every cell in a plant can produce plant hormones. They can act in their cell of origin or be transported to other portions of the plant body, with many plant responses involving the synergistic or antagonistic interaction of two or more hormones. In contrast, animal hormones are produced in specific glands and transported to a distant site for action, and they act alone.

Plant hormones are a group of unrelated chemical substances that affect plant morphogenesis. Five major plant hormones are traditionally described: auxins (particularly IAA), cytokinins, gibberellins, ethylene, and abscisic acid. In addition, other nutrients and environmental conditions can be characterized as growth factors.

### Auxins

The term auxin is derived from the Greek word *auxein*, which means "to grow." **Auxins** are the main hormones responsible for cell elongation in phototropism and gravitropism. They also control the differentiation of meristem into vascular tissue, and promote leaf development and arrangement. While many synthetic auxins are used as herbicides, IAA is the only naturally occurring auxin that shows physiological activity. Apical dominance—the inhibition of lateral bud formation—is triggered by auxins produced in the apical meristem. Flowering, fruit setting and ripening, and inhibition of **abscission** (leaf falling) are other plant responses under the direct or indirect control of auxins. Auxins also act as a relay for the effects of the blue light and red/far-red responses.

Commercial use of auxins is widespread in plant nurseries and for crop production. IAA is used as a rooting hormone to promote growth of adventitious roots on cuttings and detached leaves. Applying synthetic auxins to tomato plants in greenhouses promotes normal fruit development. Outdoor application of auxin promotes synchronization of fruit setting and dropping to coordinate the harvesting season. Fruits such as seedless cucumbers can be induced to set fruit by treating unfertilized plant flowers with auxins.

### Cytokinins

The effect of cytokinins was first reported when it was found that adding the liquid endosperm of coconuts to developing plant embryos in culture stimulated their growth. The stimulating growth factor was found to be **cytokinin**, a hormone that promotes cytokinesis (cell division). Almost 200 naturally occurring or synthetic cytokinins are known to date. Cytokinins are most abundant in growing tissues, such as roots, embryos, and fruits, where cell division is occurring. Cytokinins are known to delay senescence in leaf tissues, promote mitosis, and stimulate differentiation of the meristem in shoots and roots. Many effects on plant development are under the influence of cytokinins, either in conjunction with auxin or another hormone. For example, apical dominance seems to result from a balance between auxins that inhibit lateral buds, and cytokinins that promote bushier growth.

### Gibberellins

**Gibberellins** (GAs) are a group of about 125 closely related plant hormones that stimulate shoot elongation, seed germination, and fruit and flower maturation. GAs are synthesized in the root and stem apical meristems, young leaves, and seed embryos. In urban areas, GA antagonists are sometimes applied to trees under power lines to control growth and reduce the frequency of pruning.

GAs break dormancy (a state of inhibited growth and development) in the seeds of plants that require exposure to cold or

light to germinate. Other effects of GAs include gender expression, seedless fruit development, and the delay of senescence in leaves and fruit. Seedless grapes are obtained through standard breeding methods and contain inconspicuous seeds that fail to develop. Because GAs are produced by the seeds, and because fruit development and stem elongation are under GA control, these varieties of grapes would normally produce small fruit in compact clusters. Maturing grapes are routinely treated with GA to promote larger fruit size, as well as looser bunches (longer stems), which reduces the instance of mildew infection (**Figure 23.40**).

**Figure 23.40** In grapes, application of gibberellic acid increases the size of fruit and loosens clustering. (credit: Bob Nichols, USDA)

### Abscisic Acid

The plant hormone **abscisic acid** (ABA) was first discovered as the agent that causes the abscission or dropping of cotton bolls. However, more recent studies indicate that ABA plays only a minor role in the abscission process. ABA accumulates as a response to stressful environmental conditions, such as dehydration, cold temperatures, or shortened day lengths. Its activity counters many of the growth-promoting effects of GAs and auxins. ABA inhibits stem elongation and induces dormancy in lateral buds.

ABA induces dormancy in seeds by blocking germination and promoting the synthesis of storage proteins. Plants adapted to temperate climates require a long period of cold temperature before seeds germinate. This mechanism protects young plants from sprouting too early during unseasonably warm weather in winter. As the hormone gradually breaks down over winter, the seed is released from dormancy and germinates when conditions are favorable in spring. Another effect of ABA is to promote the development of winter buds; it mediates the conversion of the apical meristem into a dormant bud. Low soil moisture causes an increase in ABA, which causes stomata to close, reducing water loss in winter buds.

### Ethylene

**Ethylene** is associated with fruit ripening, flower wilting, and leaf fall. Ethylene is unusual because it is a volatile gas ( $C_2H_4$ ). Hundreds of years ago, when gas street lamps were installed in city streets, trees that grew close to lamp posts developed twisted, thickened trunks and shed their leaves earlier than expected. These effects were caused by ethylene volatilizing from the lamps.

Aging tissues (especially senescing leaves) and nodes of stems produce ethylene. The best-known effect of the hormone, however, is the promotion of fruit ripening. Ethylene stimulates the conversion of starch and acids to sugars. Some people store unripe fruit, such as avocados, in a sealed paper bag to accelerate ripening; the gas released by the first fruit to mature will speed up the maturation of the remaining fruit. Ethylene also triggers leaf and fruit abscission, flower fading and dropping, and promotes germination in some cereals and sprouting of bulbs and potatoes.

Ethylene is widely used in agriculture. Commercial fruit growers control the timing of fruit ripening with application of the gas. Horticulturalists inhibit leaf dropping in ornamental plants by removing ethylene from greenhouses using fans and ventilation.

### Nontraditional Hormones

Recent research has discovered a number of compounds that also influence plant development. Their roles are less understood than the effects of the major hormones described so far.

**Jasmonates** play a major role in defense responses to herbivory. Their levels increase when a plant is wounded by a predator, resulting in an increase in toxic secondary metabolites. They contribute to the production of volatile compounds that attract natural enemies of predators. For example, chewing of tomato plants by caterpillars leads to an increase in jasmonic acid levels, which in turn triggers the release of volatile compounds that attract predators of the pest.

**Oligosaccharins** also play a role in plant defense against bacterial and fungal infections. They act locally at the site of injury, and can also be transported to other tissues. **Strigolactones** promote seed germination in some species and inhibit lateral apical development in the absence of auxins. Strigolactones also play a role in the establishment of mycorrhizae, a mutualistic association of plant roots and fungi. Brassinosteroids are important to many developmental and physiological processes. Signals between these compounds and other hormones, notably auxin and GAs, amplifies their physiological effect. Apical dominance, seed germination, gravitropism, and resistance to freezing are all positively influenced by hormones. Root growth and fruit dropping are inhibited by steroids.

## Plant Responses to Wind and Touch

The shoot of a pea plant winds around a trellis, while a tree grows on an angle in response to strong prevailing winds. These are examples of how plants respond to touch or wind.

The movement of a plant subjected to constant directional pressure is called **thigmotropism**, from the Greek words *thigma* meaning “touch,” and *tropism* implying “direction.” Tendrils are one example of this. The meristematic region of tendrils is very touch sensitive; light touch will evoke a quick coiling response. Cells in contact with a support surface contract, whereas cells on the opposite side of the support expand (Figure 23.14). Application of jasmonic acid is sufficient to trigger tendril coiling without a mechanical stimulus.

A **thigmonastic** response is a touch response independent of the direction of stimulus Figure 23.24. In the Venus flytrap, two modified leaves are joined at a hinge and lined with thin fork-like tines along the outer edges. Tiny hairs are located inside the trap. When an insect brushes against these trigger hairs, touching two or more of them in succession, the leaves close quickly, trapping the prey. Glands on the leaf surface secrete enzymes that slowly digest the insect. The released nutrients are absorbed by the leaves, which reopen for the next meal.

## everyday CONNECTION for AP<sup>®</sup> Courses

The mimosa plant is also known as the sensitive plant, because its leaves are sensitive to touch and will fold inward and droop. Leaves in their normal state are shown on the left.

Figure 23.41

**Thigmomorphogenesis** is a slow developmental change in the shape of a plant subjected to continuous mechanical stress. When trees bend in the wind, for example, growth is usually stunted and the trunk thickens. Strengthening tissue, especially xylem, is produced to add stiffness to resist the wind’s force. Researchers hypothesize that mechanical strain induces growth and differentiation to strengthen the tissues. Ethylene and jasmonate are likely involved in thigmomorphogenesis.

Use the menu at the left to navigate to three short **movies**: ([http://openstaxcollege.org/l/nastic\\_mvmt](http://openstaxcollege.org/l/nastic_mvmt)) a Venus fly trap capturing prey, the progressive closing of sensitive plant leaflets, and the twining of tendrils.

A Venus fly trap response is triggered by touching the leaves \_\_\_\_.

- a. anywhere, because the whole surface of the leaf responds to touch
- b. only on the margins of the leaves where insects usually land
- c. in the center of the leaf, where the touch-sensitive hairs are located
- d. on the petiole followed by the center of leaf which signal the presence of a wandering insect

## Defense Responses against Herbivores and Pathogens

Plants face two types of enemies: herbivores and pathogens. Herbivores both large and small use plants as food, and actively chew them. Pathogens are agents of disease. These infectious microorganisms, such as fungi, bacteria, and nematodes, live off of the plant and damage its tissues. Plants have developed a variety of strategies to discourage or kill attackers.

The first line of defense in plants is an intact and impenetrable barrier. Bark and the waxy cuticle can protect against predators. Other adaptations against herbivory include thorns, which are modified branches, and spines, which are modified leaves. They discourage animals by causing physical damage and inducing rashes and allergic reactions. A plant's exterior protection can be compromised by mechanical damage, which may provide an entry point for pathogens. If the first line of defense is breached, the plant must resort to a different set of defense mechanisms, such as toxins and enzymes.

Secondary metabolites are compounds that are not directly derived from photosynthesis and are not necessary for respiration or plant growth and development. Many metabolites are toxic, and can even be lethal to animals that ingest them. Some metabolites are alkaloids, which discourage predators with noxious odors (such as the volatile oils of mint and sage) or repellent tastes (like the bitterness of quinine). Other alkaloids affect herbivores by causing either excessive stimulation (caffeine is one example) or the lethargy associated with opioids. Some compounds become toxic after ingestion; for instance, glycol cyanide in the cassava root releases cyanide only upon ingestion by the herbivore.

Mechanical wounding and predator attacks activate defense and protection mechanisms both in the damaged tissue and at sites farther from the injury location. Some defense reactions occur within minutes; others over several hours. The infected and surrounding cells may die, thereby stopping the spread of infection.

Long-distance signaling elicits a systemic response aimed at deterring the predator. As tissue is damaged, jasmonates may promote the synthesis of compounds that are toxic to predators. Jasmonates also elicit the synthesis of volatile compounds that attract parasitoids, which are insects that spend their developing stages in or on another insect, and eventually kill their host. The plant may activate abscission of injured tissue if it is damaged beyond repair.

### Think About It

1. Owners and managers of plant nurseries have to plan a lighting schedule for a long-day plant that will flower in February. What lighting periods will be most effective?
2. Storage facilities for fruits and vegetables are usually refrigerated and well ventilated. Why are these conditions advantageous?
3. Stomata close in response to bacterial infection. Create a diagram to illustrate how this is a defense mechanism for the plant.

## KEY TERMS

**abscisic acid (ABA)** plant hormone that induces dormancy in seeds and other organs

**abscission** physiological process that leads to the fall of a plant organ (such as leaf or petal drop)

**adventitious root** aboveground root that arises from a plant part other than the radicle of the plant embryo

**apical bud** bud formed at the tip of the shoot

**apical meristem** meristematic tissue located at the tips of stems and roots; enables a plant to extend in length

**auxin** plant hormone that influences cell elongation (in phototropism), gravitropism, apical dominance and root growth

**axillary bud** bud located in the axil: the stem area where the petiole connects to the stem

**bark** tough, waterproof, outer epidermal layer of cork cells

**bulb** modified underground stem that consists of a large bud surrounded by numerous leaf scales

**Casparyan strip** waxy coating that forces water to cross endodermal plasma membranes before entering the vascular cylinder, instead of moving between endodermal cells

**chromophore** molecule that absorbs light

**collenchyma cell** elongated plant cell with unevenly thickened walls; provides structural support to the stem and leaves

**companion cell** phloem cell that is connected to sieve-tube cells; has large amounts of ribosomes and mitochondrion

**compound leaf** leaf in which the leaf blade is subdivided to form leaflets, all attached to the midrib

**corm** rounded, fleshy underground stem that contains stored food

**cortex** ground tissue found between the vascular tissue and the epidermis in a stem or root

**cryptochrome** protein that absorbs light in the blue and ultraviolet regions of the light spectrum

**cuticle** waxy protective layer on the leaf surface

**cuticle** waxy covering on the outside of the leaf and stem that prevents the loss of water

**cytokinin** plant hormone that promotes cell division

**dermal tissue** protective plant tissue covering the outermost part of the plant; controls gas exchange

**endodermis** layer of cells in the root that forms a selective barrier between the ground tissue and the vascular tissue, allowing water and minerals to enter the root while excluding toxins and pathogens

**epidermis** single layer of cells found in plant dermal tissue; covers and protects underlying tissue

**ethylene** volatile plant hormone that is associated with fruit ripening, flower wilting, and leaf fall

**fibrous root system** type of root system in which the roots arise from the base of the stem in a cluster, forming a dense network of roots; found in monocots

**gibberellin (GA)** plant hormone that stimulates shoot elongation, seed germination, and the maturation and dropping of fruit and flowers

**ground tissue** plant tissue involved in photosynthesis; provides support, and stores water and sugars

**guard cells** paired cells on either side of a stoma that control stomatal opening and thereby regulate the movement of gases and water vapor

**intercalary meristem** meristematic tissue located at nodes and the bases of leaf blades; found only in monocots

**internode** region between nodes on the stem

**jasmonates** small family of compounds derived from the fatty acid linoleic acid

**lamina** leaf blade

**lateral meristem** meristematic tissue that enables a plant to increase in thickness or girth

**lenticel** opening on the surface of mature woody stems that facilitates gas exchange

**megapascal (MPa)** pressure units that measure water potential

**meristem** plant region of continuous growth

**meristematic tissue** tissue containing cells that constantly divide; contributes to plant growth

**negative gravitropism** growth away from Earth's gravity

**node** point along the stem at which leaves, flowers, or aerial roots originate

**oligosaccharin** hormone important in plant defenses against bacterial and fungal infections

**palmately compound leaf** leaf type with leaflets that emerge from a point, resembling the palm of a hand

**parenchyma cell** most common type of plant cell; found in the stem, root, leaf, and in fruit pulp; site of photosynthesis and starch storage

**pericycle** outer boundary of the stele from which lateral roots can arise

**periderm** outermost covering of woody stems; consists of the cork cambium, cork cells, and the phellogen

**permanent tissue** plant tissue composed of cells that are no longer actively dividing

**petiole** stalk of the leaf

**photomorphogenesis** growth and development of plants in response to light

**photoperiodism** occurrence of plant processes, such as germination and flowering, according to the time of year

**phototropin** blue-light receptor that promotes phototropism, stomatal opening and closing, and other responses that promote photosynthesis

**phototropism** directional bending of a plant toward a light source

**phyllotaxy** arrangement of leaves on a stem

**phytochrome** plant pigment protein that exists in two reversible forms (Pr and Pfr) and mediates morphologic changes in response to red light

**pinnately compound leaf** leaf type with a divided leaf blade consisting of leaflets arranged on both sides of the midrib

**pith** ground tissue found towards the interior of the vascular tissue in a stem or root

**positive gravitropism** growth toward Earth's gravitational center

**primary growth** growth resulting in an increase in length of the stem and the root; caused by cell division in the shoot or root apical meristem

**rhizome** modified underground stem that grows horizontally to the soil surface and has nodes and internodes

**root cap** protective cells covering the tip of the growing root

**root hair** hair-like structure that is an extension of epidermal cells; increases the root surface area and aids in absorption of water and minerals

**root system** belowground portion of the plant that supports the plant and absorbs water and minerals

**runner** stolon that runs above the ground and produces new clone plants at nodes

**sclerenchyma cell** plant cell that has thick secondary walls and provides structural support; usually dead at maturity

**secondary growth** growth resulting in an increase in thickness or girth; caused by the lateral meristem and cork cambium

**sessile** leaf without a petiole that is attached directly to the plant stem

**shoot system** aboveground portion of the plant; consists of non-reproductive plant parts, such as leaves and stems, and reproductive parts, such as flowers and fruits

**sieve-tube cell** phloem cell arranged end to end to form a sieve tube that transports organic substances such as sugars and amino acids

**simple leaf** leaf type in which the lamina is completely undivided or merely lobed

**sink** growing parts of a plant, such as roots and young leaves, which require photosynthate

**source** organ that produces photosynthate for a plant

**statolith** (also, **amyloplast**) plant organelle that contains heavy starch granules

**stele** inner portion of the root containing the vascular tissue; surrounded by the endodermis

**stipule** small green structure found on either side of the leaf stalk or petiole

**stolon** modified stem that runs parallel to the ground and can give rise to new plants at the nodes

**strigolactone** hormone that promotes seed germination in some species and inhibits lateral apical development in the absence of auxins

**tap root system** type of root system with a main root that grows vertically with few lateral roots; found in dicots

**tendril** modified stem consisting of slender, twining strands used for support or climbing

**thigmomorphogenesis** developmental response to touch

**thigmonastic** directional growth of a plant independent of the direction in which contact is applied

**thigmotropism** directional growth of a plant in response to constant contact

**thorn** modified stem branch appearing as a sharp outgrowth that protects the plant

**tracheid** xylem cell with thick secondary walls that helps transport water

**translocation** mass transport of photosynthates from source to sink in vascular plants

**transpiration** loss of water vapor to the atmosphere through stomata

**trichome** hair-like structure on the epidermal surface

**tuber** modified underground stem adapted for starch storage; has many adventitious buds

**vascular bundle** strands of stem tissue made up of xylem and phloem

**vascular stele** strands of root tissue made up of xylem and phloem

**vascular tissue** tissue made up of xylem and phloem that transports food and water throughout the plant

**venation** pattern of veins in a leaf; may be parallel (as in monocots), reticulate (as in dicots), or dichotomous (as in *Ginkgo biloba*)

**vessel element** xylem cell that is shorter than a tracheid and has thinner walls

**water potential ( $\Psi_w$ )** the potential energy of a water solution per unit volume in relation to pure water at atmospheric pressure and ambient temperature

**whorled** pattern of leaf arrangement in which three or more leaves are connected at a node

## CHAPTER SUMMARY

### 23.1 The Plant Body

A vascular plant consists of two organ systems: the shoot system and the root system. The shoot system includes the aboveground vegetative portions (stems and leaves) and reproductive parts (flowers and fruits). The root system supports the plant and is usually underground. A plant is composed of two main types of tissue: meristematic tissue and permanent tissue. Meristematic tissue consists of actively dividing cells found in root and shoot tips. As growth occurs, meristematic tissue differentiates into permanent tissue, which is categorized as either simple or complex. Simple tissues are made up of similar cell types; examples include dermal tissue and ground tissue. Dermal tissue provides the outer covering of the plant. Ground tissue is responsible for photosynthesis; it also supports vascular tissue and may store water and sugars. Complex tissues are made up of different cell types. Vascular tissue, for example, is made up of xylem and phloem cells.

### 23.2 Stems

The stem of a plant bears the leaves, flowers, and fruits. Stems are characterized by the presence of nodes (the points of attachment for leaves or branches) and internodes (regions between nodes).

Plant organs are made up of simple and complex tissues. The stem has three tissue systems: dermal, vascular, and ground tissue. Dermal tissue is the outer covering of the plant. It contains epidermal cells, stomata, guard cells, and trichomes. Vascular tissue is made up of xylem and phloem tissues and conducts water, minerals, and photosynthetic products. Ground tissue is responsible for photosynthesis and support and is composed of parenchyma, collenchyma, and sclerenchyma cells.

Primary growth occurs at the tips of roots and shoots, causing an increase in length. Woody plants may also exhibit secondary growth, or increase in thickness. In woody plants, especially trees, annual rings may form as growth slows at the end of each season. Some plant species have modified stems that help to store food, propagate new plants, or discourage predators. Rhizomes, corms, stolons, runners, tubers, bulbs, tendrils, and thorns are examples of modified stems.

### 23.3 Roots

Roots help to anchor a plant, absorb water and minerals, and serve as storage sites for food. Taproots and fibrous roots are the two main types of root systems. In a taproot system, a main root grows vertically downward with a few lateral roots. Fibrous root systems arise at the base of the stem, where a cluster of roots forms a dense network that is shallower than a taproot. The growing root tip is protected by a root cap. The root tip has three main zones: a zone of cell division (cells are actively dividing), a zone of elongation (cells increase in length), and a zone of maturation (cells differentiate to form different kinds of cells). Root vascular tissue conducts water, minerals, and sugars. In some habitats, the roots of certain plants may be modified to form aerial roots or epiphytic roots.

### 23.4 Leaves

Leaves are the main site of photosynthesis. A typical leaf consists of a lamina (the broad part of the leaf, also called the blade) and a petiole (the stalk that attaches the leaf to a stem). The arrangement of leaves on a stem, known as phyllotaxy, enables maximum exposure to sunlight. Each plant species has a characteristic leaf arrangement and form. The pattern of leaf arrangement may be alternate, opposite, or spiral, while leaf form may be simple or compound. Leaf tissue consists of the epidermis, which forms the outermost cell layer, and mesophyll and vascular tissue, which make up the inner portion of the leaf. In some plant species, leaf form is modified to form structures such as tendrils, spines, bud scales, and needles.

### 23.5 Transport of Water and Solutes in Plants

Water potential ( $\Psi$ ) is a measure of the difference in potential energy between a water sample and pure water. The water

potential in plant solutions is influenced by solute concentration, pressure, gravity, and matric potential. Water potential and transpiration influence how water is transported through the xylem in plants. These processes are regulated by stomatal opening and closing. Photosynthates (mainly sucrose) move from sources to sinks through the plant's phloem. Sucrose is actively loaded into the sieve-tube elements of the phloem. The increased solute concentration causes water to move by osmosis from the xylem into the phloem. The positive pressure that is produced pushes water and solutes down the pressure gradient. The sucrose is unloaded into the sink, and the water returns to the xylem vessels.

### 23.6 Plant Sensory Systems and Responses

Plants respond to light by changes in morphology and activity. Irradiation by red light converts the photoreceptor phytochrome to its far-red light-absorbing form—Pfr. This form controls germination and flowering in response to length of day, as well as triggers photosynthesis in dormant plants or those that just emerged from the soil. Blue-light receptors, cryptochromes, and phototropins are responsible for phototropism. Amyloplasts, which contain heavy starch granules, sense gravity. Shoots exhibit negative gravitropism, whereas roots exhibit positive gravitropism. Plant hormones—naturally occurring compounds synthesized in small amounts—can act both in the cells that produce them and in distant tissues and organs. Auxins are responsible for apical dominance, root growth, directional growth toward light, and many other growth responses. Cytokinins stimulate cell division and counter apical dominance in shoots. Gibberellins inhibit dormancy of seeds and promote stem growth. Abscisic acid induces dormancy in seeds and buds, and protects plants from excessive water loss by promoting stomatal closure. Ethylene gas speeds up fruit ripening and dropping of leaves. Plants respond to touch by rapid movements (thigmotropy and thigmonasty) and slow differential growth (thigmomorphogenesis). Plants have evolved defense mechanisms against predators and pathogens. Physical barriers like bark and spines protect tender tissues. Plants also have chemical defenses, including toxic secondary metabolites and hormones, which elicit additional defense mechanisms.

## REVIEW QUESTIONS

1. Students are sketching diagrams of the shoot system of angiosperms for a plant anatomy class. These lists describe diagrams made by four students. Which diagram represents the shoot system incorrectly?
  - a. leaves, stem, fruit, flowers
  - b. stem, fruit, leaves, branches
  - c. flowers, leaves, branches, stem
  - d. stem, hair roots, leaves, flowers, branches
2. An herbicide causes roots to shrivel and die. What is the most direct consequence for a plant treated with the herbicide?
  - a. The plant will grow normally but will not bloom.
  - b. The plant will dry out because water is not reaching all its organs.
  - c. New leaves will form to compensate for the dying of roots
  - d. The plant will grow normally but will not produce fruit
3. Scientists label cells in the lateral meristem of a sapling with a dye to follow the developmental fate of the cells. After several weeks, sections are prepared from the sapling and observed under the microscope. Which tissues are most likely to be stained by the dye that was injected into the lateral meristem?
  - a. Vascular tissue to transport nutrients and water
  - b. The tip of plant to promote growth of plant
  - c. Secondary xylem to increase girth of stem
  - d. Epidermis to cover the plant
4. A lab technician is looking for a slide that shows an example of permanent tissue. Which slide is the best choice?
  - a. a slide of the apical bud of a stem
  - b. a slide obtained from the intercalary meristems
  - c. lateral meristem in the vascular cambium
  - d. secondary xylem
5. Which region of a plant is most likely to contribute to an increase in its length?
  - a. tip of leaves
  - b. dermal layer
  - c. vascular bundles
  - d. tip of the root
6. You are measuring the effect of a new fertilizer on the growth of lawns. Which of the following tissues should be the target of the fertilizer?
  - a. apical meristem
  - b. lateral meristem
  - c. intercalary meristem
  - d. vascular bundle
7. The dermal tissue of a plant provides \_\_ for the plant.

- a. transport of water
- b. transport of minerals
- c. support
- d. protection

**8.** A branch of celery is soaked in a glass of water containing food dye. Soon, the tough fibers in celery branch are colored. What tissue do the tough fibers contain?

- a. dermal tissue
- b. xylem
- c. phloem
- d. ground tissue

**9.** A plant biologist is examining sections of plant tissue under the microscope. The slides are not labeled and the biologist is interested in simple tissues. Which of the following slides is a sample of a simple tissue?

- a. cells dividing rapidly in a stem
- b. root cambium showing different types of cells
- c. parenchyma showing only one type of cell
- d. leaf displaying the vascular bundle where diverse types of cells are involved in transport

**10.** Students are asked to sort tissue slides into simple and complex tissues. How should they recognize a complex tissue through the microscope?

- a. Complex tissue has a variety of cell types that fulfill different functions.
- b. Only complex tissue is observed in adult plants.
- c. Complex tissue appears only in lateral roots and branches.
- d. Complex tissues contain cells that are strikingly different in appearance but perform the same function.

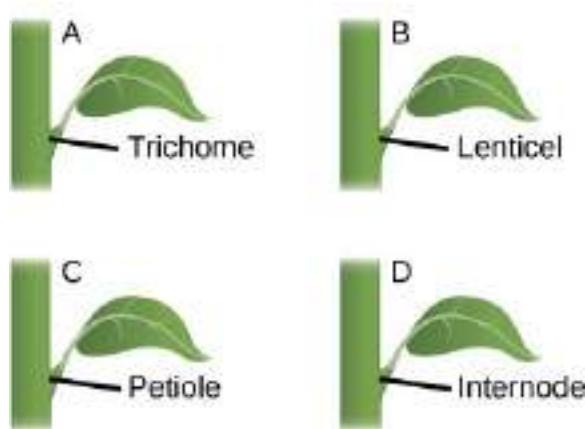

**11.** Students are sketching diagrams of the reproductive system of angiosperms for a plant anatomy class. These lists describe diagrams made by four students. Which diagram represents the reproductive system correctly?

- a. hair roots, lateral roots, and taproot
- b. stem, branches, and leaves
- c. flowers and fruit
- d. leaves, petioles, and branches

**12.** Plant scientists are interested in isolating meristematic tissue for an experiment. They sample several regions of a plant. Which sample is most likely to contain meristematic tissue?

- a. the thin epidermis that covers an onion bulb
- b. a sample of fruit tissue
- c. a sample of actively dividing cells located at the tip of an onion root
- d. a region of the mesenchyme

**13.**

This sketch of a stem shows the region to which leaves are attached. Which version of the sketch is correctly labeled?

- a. version A
- b. version B
- c. version C
- d. version D

**14.** A student examines a plant part and concludes that it is part of a stem. The presence of \_\_\_\_\_ fully justifies the student's conclusion.

- a. vascular tissue
- b. nodes and internodes
- c. epidermal layer
- d. stored carbohydrates

**15.** A student reported vascular tissue while inspecting a cross-section of a plant stem under the microscope. Which cells would allow the student to identify vascular tissue?

- a. tracheids, vessel elements, sieve-tube cells, and companion cells
- b. cells actively dividing at the apex of the stem
- c. parenchyma cells at the center of the section
- d. cells covered by a cuticle at the outside edge of the section

**16.** While using a microscope to observe a stem section stained with a dye that binds lignin, a student notices that some cells with thick cell walls and large hollow centers are preferentially stained. He concludes that those cells belong to the \_\_\_\_\_.

- a. meristematic tissue
  - b. vascular tissue
  - c. ground tissue
  - d. dermal tissue
- 17.** Scientists are cataloguing slides of plant cross-sections. They are interested in finding examples of secondary growth. Which example contributes to secondary growth?
- a. apical meristem, which contributes to increase in length
  - b. vascular cambium, which contributes to increase in thickness or girth
  - c. root region, which shows an increase in root hairs
  - d. stems, which show an increase in number of leaves
- 18.** Where is the vascular cambium located in an established woody plant?
- a. between the primary xylem and the primary phloem
  - b. between the secondary xylem and the primary phloem
  - c. between the secondary xylem and the secondary phloem
  - d. between the primary xylem and the secondary phloem
- 19.** Dendrochronology is the science of dating the age of a tree by counting the annual rings in a tree trunk. If scientists are determining the age of a tree by dendrochronology, what tissue are they looking at?
- a. primary xylem
  - b. secondary xylem
  - c. primary phloem
  - d. vascular cambium
- 20.** While examining the stump of a recently cut tree, you count four thick rings alternating with four rings that are much narrower and appear denser. From this observation, you should conclude that the tree is \_\_\_\_.
- a. two years old, because each ring corresponds to a season
  - b. three years old, because the first ring you observe is the primary xylem
  - c. four years old, because secondary xylem grows only in the spring and fall of each year
  - d. eight years old, because there are eight rings in all
- 21.** Many forms of modified organs exist in plants. What is a rhizome?
- a. an underground stem with fleshy leaves modified for food storage as in onions
  - b. a solid, underground stem covered with scales formed by some plants such as crocuses
  - c. an aboveground stem with buds as seen in strawberry plants
  - d. a modified horizontal stem that grows underground as seen in irises
- 22.** Modified organs are part of survival strategies of plants. Which of these plants has a flattened, photosynthetic stem that could be mistaken for a leaf?
- a. fern
  - b. cactus
  - c. potato
  - d. iris
- 23.** Analyzing cross-sections of different parts of a plant in a plant anatomy class, students categorized the most frequently encountered types of cells in plant tissues. Which student gave the most accurate report?
- a. Student A reported that meristematic cells were the most abundant.
  - b. Student B tallied mostly collenchyma cells.
  - c. Student C noticed mostly sclerenchyma cells.
  - d. Student D observed that parenchyma cells were the most abundant.
- 24.** A carrot is an example of a tap root. Which of these can also be classified as a tap root?
- a. the large network of superficial roots of a cactus
  - b. a dandelion anchored by a long main root that penetrates deep into the soil
  - c. a banyan tree's system of roots that dangle from the branches
  - d. a round organ that stores carbohydrates
- 25.** Some weeds are anchored by taproots. They cause problems to gardeners because they are \_\_\_\_.
- a. easy to pull up because the root system is shallow
  - b. difficult to pull up because their taproots penetrate deep into the soil
  - c. difficult to pull up because they are anchored by an extensive network of roots
  - d. easy to pull up because there is not a large network to anchor the plant
- 26.** One of the major concepts of biology is that form follows function. If that is so, what can be deduced from the shape and location of the root cap?

- a. It provides protection to the root tip.  
 b. It absorbs water and minerals.  
 c. It acts as a storage tissue.  
 d. It replicates actively to elongate the root.
- 27.** A technician is preparing microscope slides that will display the different stages of mitosis from root samples. He compares sections from several areas of the root. Which is the best prediction of his observation?
- The technician will see mostly mitotic cells in the root cap.
  - The technician will observe mitotic figures in the meristematic tissue below the cap.
  - The technician will observe cell division in the elongation zone.
  - The technician will see that most mitotic cells are in the maturation zone.
- 28.** Selective uptake of minerals in the root is measured and the results are analyzed. If you analyze the data, what should you see?
- Pericycle is the tissue where selectivity takes place.
  - The endodermis acts as a selective barrier for minerals taken up by the root.
  - The epidermis acts as a selective barrier for minerals.
  - The root cap functions as a selective barrier for minerals taken up by the root.
- 29.** Sudan Red dye stains primarily waxy, hydrophobic material. A root is soaked in Sudan Red and analyzed for stain retention. What is a scientist observing sections of the root under a microscope likely to see?
- The cells in the cortex show the deepest stain.
  - The tracheids in the xylem contain mostly lipid droplets stained with Sudan Red.
  - The Caspary strip will show the deepest coloring.
  - The sieve elements in the phloem show staining with Sudan Red because of transported oil droplets.
- 30.** In environments where light is scarce, some plants grow on other plants to reach light. Which root system would best support this mode of life?
- Epiphytic root system in the air
  - Prop roots that support the trees to stand in muddy soil
  - Adventitious roots that grow above ground
  - Taproots that penetrate the soil
- 31.** A section of buttercup root is stained with iodine, which stains starch blue. Where would you expect to find the blue granules indicative of starch?
- parenchymal cells of the cortex
  - cells of phloem
  - cells of the epidermis
  - cells of the endodermis and pericycle
- 32.** Which of the following best describes a fibrous root system?
- covers a limited surface and contains few roots
  - consists of a single main root with adjacent smaller roots
  - covers a large area and contains an extensive network of roots
  - contains several major, interconnected roots
- 33.** Ethylene promotes the fall of leaves by triggering the death of cells and abscission. What region of the leaf responds to ethylene?
- the lamina, where photosynthesis takes place
  - the vein, which carries nutrients and water in and out of the leaf
  - the petiole, which attaches the leaf to the stem
  - the margin, which is serrated and may be sharp
- 34.** A horticulture student is classifying plants as dicots or monocots according to their leaf structure. How is a dicot leaf recognizable?
- It does not have stipules
  - The veins form a network pattern.
  - The veins are parallel.
  - The veins form forks and fan out.
- 35.** Multiple leaves attached to the same node are fairly unusual. One example is found on the macadamia nut tree. The leaf arrangement in the macadamia tree is best characterized as \_\_\_\_.
- whorled
  - opposite
  - tripled
  - alternate
- 36.** You picked leaves while on a hike. One specimen appears to show an opposite arrangement. On closer inspection, you notice that those are not leaves, but leaflets attached to a midrib vein. What type of leaf arrangement are you observing?
- palmately compound
  - pinnately compound
  - simple whorled
  - simple spiral
- 37.** Chlorophyll, the primary photosynthetic pigment,

emits light in the red region of the visible spectrum. The presence of chlorophyll correlates with photosynthetic capacity. Under a fluorescent microscope, what part of a leaf would fluoresce in the red region of the spectrum?

- a. vascular bundle
- b. epidermis
- c. mesophyll
- d. cuticle

38. A pulse of radioactive carbon dioxide ( $\text{CO}_2$ ) is provided to isolated leaves. In which tissue would you expect to see radioactive glucose appear first?

- a. in the cells of the mesophyll
- b. in the sieve elements of the phloem
- c. epidermis
- d. vessels of the xylem

39. Which adaptation is most likely to be found in a desert environment?

- a. broad leaves to capture sunlight
- b. spines instead of leaves
- c. needle-like leaves
- d. wide, flat leaves that can float

40. In the collection of a botanical garden, plants are classified according to the environments in which they thrive. What plant would have large leaves covered with a thick upper cuticle and wide flat blades and possess large air spaces (chambers) within its mesophyll tissue?

- a. a water lily floating on water
- b. a pine tree growing in the cold and dry taiga
- c. a cactus growing in a hot, sunny, and dry environment
- d. an orchid hanging from a tree in a tropical forest

41. If a gardener trims leaves off of the stem of a rose, which part of the leaf is cut?

- a. petiole
- b. lamina
- c. stipule
- d. midrib

42. On a field trip, students collect a few samples to analyze back in their classroom. One student picks a blade of grass in the field and identifies it as a dicot leaf, but his partner thinks it is a monocot. Which explanation supports his partner's opinion?

- a. The leaf displays a thin lamina.
- b. There is no petiole.
- c. The margins are serrated.
- d. The venation is parallel.

43. Which of the following physical components of the total water potential cannot be manipulated by the plant because it represents the interaction between water and hydrophilic molecules lining the vessels and tracheids?

- a. pressure
- b. solute concentration
- c. gravity
- d. matric potential

44. If the concentration of solute increases in a cell, the water potential will \_\_\_\_\_ inside the cell and water will move \_\_\_\_\_ the cell.

- a. increase; out of
- b. increase; into
- c. decrease; into
- d. decrease; out of

45. Plants can modify their water potential by opening and closing their stomata to modulate the rate of respiration according to environmental conditions. Which of the following environmental conditions would cause the stomata to close?

- a. increased temperature
- b. high oxygen concentration
- c. high relative humidity
- d. high light levels

46. Plants regulate their internal water potential by opening and closing stomata. Which events take place when stomata open?

- a. Water vapor is lost to the external environment, increasing the rate of transpiration.
- b. Water vapor is lost to the external environment, decreasing the rate of transpiration.
- c. Water vapor enters the spaces in the mesophyll, increasing the rate of transpiration.
- d. The rate of photosynthesis drops when stomata open.

47. A pulse of sugars labelled with a fluorescent dye is supplied to leaves of young plants. After a brief interval, tissue sections are obtained from the plant and examined under the fluorescence microscope. Tissues are scored for the presence of fluorescence and ranked from very high to low fluorescence. Which cells would contain the most fluorescence?

- a. xylem
- b. companion cells
- c. sieve elements
- d. epidermis

48. Sugars produced in the leaf are distributed throughout the plant body. An experimenter supplies plants with a

pulse of radiolabeled CO<sub>2</sub> in a control chamber. The movement of radioactively labeled sugar is monitored in the plant by analyzing different cells content over time. Where will the radiolabeled sugar appear immediately after detection in the leaf cells?

- a. tracheids and vessel elements
- b. tracheids and companion cells
- c. vessel elements and companion cells
- d. sieve-tube elements and companion cells

**49.** Solute potential decreases when solutes are added to a cell. The consequence is to draw water into the cell. Which of these terms corresponds to solute potential?

- a. water potential
- b. pressure potential
- c. osmotic potential
- d. negative potential

**50.**

| Photoreceptor | Active Region of the Spectrum |
|---------------|-------------------------------|
| Phototropin   | Blue                          |
| Phytochrome   | Red–far red                   |
| Carotenoids   | Blue                          |
| Chlorophyll   | Blue–red                      |

Plants have many light responses, including photosynthesis, photoperiodism, and phototropism (growing toward a light source). Specific wavelengths of light absorbed by different photoreceptors trigger responses. This table shows some of the most common photoreceptors and pigments and the major regions of the spectrum in which they are active. Research shows that plants bend toward blue light. Even mutant plants that lack carotenoids will bend toward blue light. The photoreceptor is likely \_\_\_\_\_.

- a. phytochrome
- b. chlorophyll
- c. phototropin
- d. carotenoids

**51.** Plant flowering is an example of photoperiodism, the response to the length of nights or periods of darkness. A plant that responds to short nights followed by

increasingly longer nights will most likely flower in \_\_\_\_\_.

- a. spring
- b. summer
- c. autumn
- d. winter

**52.** Gravitropism is plant growth in response to gravity. A dahlia stem was toppled by the wind and is lying lies on the ground. After a few days, you would likely notice that \_\_\_\_\_ .

- a. the stem is growing by curving toward the roots
- b. the stem is growing by trailing on the ground
- c. the stem is growing by curving upward
- d. the plant is wilting

**53.** Plants most likely detect gravity by sensing the direction in which some components respond to gravity. A mutant plant has roots that grow in all directions. Which organelle would you expect to be missing in the cell?

- a. mitochondria
- b. amyloplast
- c. chloroplast
- d. nucleus

**54.**

| Plate | Hormone          |
|-------|------------------|
| A     | Abscisic acid    |
| B     | Cytokinin        |
| C     | Ethylene         |
| D     | Gibberellic acid |

In an experiment to release seeds from dormancy, several hormones were applied to seeds and germination rates were computed. Which plate likely showed the highest rate of germination?

- a. abscisic acid
- b. cytokinin
- c. ethylene
- d. gibberellic acid

**55.** Green bananas or unripe avocados can be kept in a

brown bag to ripen faster. What hormone is involved?

- a. cytokinin
- b. abscisic acid
- c. ethylene
- d. gibberellic acid

56. A lab teacher wants to demonstrate thigmotrophic behavior of a plant. Which of these experiments is the best choice?

- a. Observe flowering of a plant after a brief red light irradiation in the middle of a dark period.
- b. Observe whether seedlings bend towards blue light.
- c. Observe whether a tree grows bent in the direction of the prevailing wind.
- d. Touch the plant *Mimosa pudica* and observe the closing of the leaflets.

57. A lab teacher wants to demonstrate thigmotropic behavior of a plant. Which of these experiments is the best choice?

- a. roots growing downwards
- b. venus fly trap snapping on an insect
- c. seedling germinating under a stone and growing upward and away from the stone
- d. plant growing towards a shaded area

58. Which is a protection against microbial pathogens?

- a. thorns and spines
- b. cutin and suberin
- c. neurotoxic compounds
- d. bitter-tasting alkaloids

59. Many secondary alkaloids are poisonous to the nervous system. What organisms are targeted by the alkaloids?

- a. bacteria
- b. herbivores
- c. fungi
- d. viruses

60. Red light converts phytochrome red (Pr) to \_\_\_\_.

- a. an inactive form of Pr
- b. a breakdown product
- c. the far red light absorbing form called Pfr
- d. cryptochrome

61. Circadian rhythm refers to a pattern of behavior that recurs on a daily schedule in the absence of an external stimulus. Flowers open and close according to a circadian rhythm. If a plant is transferred to a dark environment, what will happen?

- a. Flowers will stay closed.
- b. Flowers will stay open.
- c. Flowers will open and close every day at the same time.
- d. Flowers will open and close at random times.

## CRITICAL THINKING QUESTIONS

62. Why are plants with shallow roots more easily damaged by some herbivores?

- a. Shallow roots do not anchor the plant to the ground and can be easily uprooted. Once the plant is no longer in the ground, the roots are unable to grow back.
- b. Plants with shallow roots do not anchor the plant to the ground; meristems can be easily damaged and cannot grow back when not in the ground.
- c. Shallow roots do not anchor the plant to the ground and can be easily uprooted. Once the plant is no longer in the ground, roots take a long time to grow back.
- d. Shallow roots anchor the plant to the ground strongly but can be easily uprooted, and they grow back very slowly.

63. A researcher intends to test the effects of several growth factors on the differentiation of plant tissue. What would be the best choice of experimental tissue?

- a. dermal tissue
- b. meristematic tissue
- c. vascular tissue
- d. ground tissue

64. How do the locations and the functions of the three types of meristematic tissues compare?

- a. Apical meristems found in the tip of stems and roots promote growth by elongation; lateral meristems found at nodes and bases of leaf blades promote increase in length and intercalary meristems found in the vascular and cork cambia promote increase in girth.
- b. Apical meristems found at nodes and bases of leaf blades promote growth by elongation; lateral meristems found in the vascular and cork cambia promote increase in girth and intercalary meristems found in the tip of stems and roots promote increase in length.
- c. Apical meristems found in the tip of stems and roots promote growth by elongation; lateral meristems found in the vascular and cork cambia promote increase in girth and intercalary meristems found at nodes and bases of leaf blades promote increase in length.
- d. Apical meristems found in the tip of stems and roots promote growth by elongation; lateral meristems found in the vascular and cork cambia promote increase in length and intercalary meristems found at nodes and bases of leaf blades promote increase in length.

**65.** In an experiment on transport in plants, seedlings are exposed to radiolabeled minerals. In a second experiment, plants are provided with CO<sub>2</sub> that is labeled with <sup>14</sup>C. At the end of each experiment, tissue slices are analyzed for the presence of radiolabeled minerals and radioactive sucrose. Which plant tissue would show the presence of labeled minerals and which would show the presence of radioactive sucrose?

- a. Phloem tissue would show the presence of labeled minerals and xylem tissue would show the presence of radioactive sucrose.
- b. Xylem tissue would show the presence of labeled minerals and phloem tissue would show the presence of radioactive sucrose.
- c. Parenchyma would show the presence of labeled minerals and sclerenchyma would show the presence of radioactive sucrose.
- d. Sclerenchyma would show the presence of labeled minerals and parenchyma would show the presence of radioactive sucrose.

**66.** How could the morphology of cells observed microscopically indicate that the specimen is probably simple tissue?

- a. Simple tissue is made of cells that have different shapes, so the specimen will show oval, polygonal, and other shapes.
- b. Simple tissue is made of cells that have intercellular spaces, so the specimen will contain spaces.
- c. Simple tissue is made of cells that are elongated and tapered, so the specimen will show elongated cells.
- d. Simple tissue is made of cells that are morphologically similar, so the specimen will appear uniform.

**67.** Which statements list two advantages of a taproot?

- a. It anchors the plant, so that it is not easily uprooted by predators or wind. It is a sink for proteins that is protected from herbivores by being underground.
- b. It anchors the plant, so that it is not easily uprooted by predators or wind. It is a source of starches that is protected from herbivores by being underground.
- c. It anchors the plant, so that it cannot be uprooted by predators or wind. It is a sink for starches that is protected from herbivores by being underground.
- d. It anchors the plant, so that it is not easily uprooted by predators or wind. It is a sink for starches that is protected from herbivores by being underground.

**68.** Students observe several slides of tissue cross-sections under the microscope. They are asked to develop a key system to classify the slides as coming from either monocot or dicots. What key system should the students develop?

- a. In monocots, the vascular bundles form a distinct ring. In dicots, the vascular bundles are scattered in the ground tissue.
- b. In monocots, the vascular tissue forms a characteristic X shape in the center. In dicots, the phloem and xylem cells are scattered in the pith.
- c. In monocots, the vascular bundles are scattered in the ground tissue. In dicots the vascular bundles form a distinct ring.
- d. In monocot roots, the pith is absent or very small. In dicots, the pith is large and well developed.

**69.** What are the functions of stomata and guard cells, and what would happen to a plant if these cells did not function correctly?

- a. Guard cells allow carbon dioxide to enter and exit the plant. Stomata regulate the opening and closing of guard cells. If the cells didn't function, photosynthesis and transpiration would cease, which would interfere with the necessary continuous flow of water upward from roots to leaves.
- b. Stomata allow oxygen to enter and exit the plant. Guard cells regulate the opening and closing of stomata. If the cells didn't function, photosynthesis would continue but transpiration would cease, which would interfere with the necessary continuous flow of water upward from roots to leaves.
- c. Guard cells allow carbon dioxide to enter and exit the plant. Stomata regulate the opening and closing of guard cells. Transpiration and in turn, photosynthesis would not occur which is necessary to maintain a continuous flow of water upwards from the roots to the leaves.
- d. Stomata allow gases to enter and exit the plant. Guard cells regulate the opening and closing of stomata. Photosynthesis and, in turn, transpiration, would not occur which is necessary to maintain a continuous flow of water upwards from the roots to the leaves.

**70.** An herbicide is developed that impairs the function of the cork cambium in woody plants. Which changes in the plant should be monitored to gauge the effectiveness of the herbicide?

- a. Cork will not be produced and the plant will not increase in girth.
- b. Excess cork will be produced and annual rings will not be formed.
- c. Cork will not be produced and the plant will not be able to exchange gases.
- d. Excess cork will be produced and the plant will not increase in girth.

**71.** Besides the age of a tree, what additional information can annual rings reveal?

- a. Annual rings can also indicate the height of the tree.
- b. Annual rings can also indicate the climatic conditions that prevailed during each growing season.
- c. Annual rings can also indicate in which season the tree was sown.
- d. Annual rings can also give an estimation of how long a particular tree is going to live.

**72.** Modified stems give an advantage to plants. What advantage do rhizomes, stolons, and runners provide? What advantages do corms, tubers, and bulbs provide?

- a. Rhizomes, stolons and runners give rise to new plants that are the clones of the parents and they store food. Corms, tubers, and bulbs can also produce new plants.
- b. Rhizomes, stolons, and runners give rise to new plants that are the different from the parents. Corms, tubers, and bulbs can also produce new plants as well as store food.
- c. Rhizomes, stolons and runners give rise to new plants that are the clones of the parents. Corms, tubers, and bulbs can also produce new plants as well as store food.
- d. Rhizomes, stolons and runners give rise to new plants that are similar to the parents but show genetic variability. Corms, tubers, and bulbs can also produce new plants as well as store food.

**73.** A time course is developed to follow the fate of the vascular bundles in the stem of dicots. Sections along the stem are fixed, stained, and observed under a microscope. What happens to the vascular bundles in the stem of a dicot as the plant matures?

- a. The vascular bundles join to form growth rings.
- b. The vascular bundles divide into primary xylem and primary phloem.
- c. The vascular bundles divide into secondary xylem and primary phloem.
- d. The vascular bundles die out.

**74.** Which description correctly compares a tap root system with a fibrous root system?

- a. A tap root system, such as that of carrots, has a single main root that grows down. A fibrous root system, such as that of wheat, forms a dense network of roots that is closer to the soil surface. Fibrous root systems are found in monocots and tap root systems are found in dicots.
- b. A fibrous root system, such as that of a carrot, has a single main root that grows down. A taproot system, such as that of wheat, forms a dense network of roots that is closer to the soil surface. Fibrous root systems are found in monocots and tap root systems are found in dicots.
- c. A taproot system, such as that of rice, has a single main root that grows down. A fibrous root system, such as that of a carrot, forms a dense network of roots that is closer to the soil surface. Fibrous root systems are found in monocots and tap root systems are found in dicots.
- d. A taproot system, such as that of a carrot, has a single main root that grows down. A fibrous root system, such as that of wheat, forms a dense network of roots that is closer to the soil surface. Taproot systems are found in monocots and fibrous root systems are found in dicots.

**75.** What is the advantage of a root cap covering the apical meristem of a root?

- a. It provides protection and helps in absorption.
- b. It increases the surface area of root for absorption of water and minerals.
- c. It protects meristem against injury and provides lubrication for the growing root to dig through soil.
- d. It protects the meristem against injury and helps in absorption.

**76.** How does selective uptake of water and mineral take place in a root?

- a. Water and minerals must follow entirely a path between cells, where selectivity occurs.
- b. Water and minerals must follow entirely a path between cells, where no selectivity occurs.
- c. Water and minerals must cross the endodermis.
- d. Water and minerals must cross the tracheids of the xylem.

**77.** What are the advantages to a plant of storing a food reserve underground?

- a. Food reserves are more nutritious underground. The soil conditions make these food reserves abundant.
- b. Food reserves underground are hidden from potential predators. The soil conditions make these food reserves abundant.
- c. Food reserves are more nutritious underground. The soil conditions such as moisture and temperature are less variable.
- d. Food reserves underground are hidden from potential predators. Soil conditions such as moisture and temperature are less variable.

**78.** Some desert plants have taproots that extend up to 20-30 feet underground. Others have fibrous root systems that cover wide areas. What are the advantages of a deep taproot and the advantages of a fibrous root system in a desert?

- a. A deep taproot can reach the deeper soil regions that stay moist after several rainfalls. A shallow fibrous system provides additional support to anchor the plant in the desert.
- b. A deep taproot provides additional support to anchor the plant in the desert. A shallow fibrous system increases the amount of water that can be absorbed after a light rainfall when the soil dries quickly in the desert.
- c. A deep taproot increases the amount of water that can be absorbed after a light rainfall when the soil dries quickly in the desert. A shallow fibrous system can reach the deeper soil regions that stay moist after several rainfalls.
- d. A deep taproot can reach the deeper soil regions that stay moist after several rainfalls. A shallow fibrous system increases the amount of water that can be absorbed after a light rainfall when the soil dries quickly in the desert.

**79.** Samples of leaves from monocots and dicots are piled on the table in a laboratory and students are sorting the leaves. What information will help them know which leaves to identify as monocots?

- a. Bulliform cells are usually absent from monocots whereas they are present on the upper epidermis of dicot leaves.
- b. Monocots have leaves with parallel venation and dicot leaves have reticulate, net-like venation.
- c. Dorsiventral symmetry is observed in monocot leaves whereas isobilateral symmetry is observed in dicot leaves.
- d. Monocots have leaves with reticulate, net-like venation and dicot leaves have parallel venation.

**80.** How does a compound leaf give a selective advantage to avoid herbivory?

- a. Compound leaves produce certain types of chemical compounds that are harmful to herbivores.
- b. It is more efficient for large herbivores to eat large, simple leaves.
- c. Compound leaves are thicker than simple leaves.
- d. It is more efficient for large herbivores to eat the small leaflets of compound leaves.

**81.** Stomata are usually found in higher numbers on the abaxial or bottom surface of a leaf. What is the advantage of such an arrangement?

- a. Presence of stomata on the abaxial or bottom surface ensures that no, or very little, water is lost due to guttation.
- b. The abaxial or bottom surface receives more sunlight and water evaporates faster by transpiration.
- c. Herbivores do not prefer to eat leaves with stomata on the abaxial or bottom surface.
- d. The adaxial or upper surface receives more sunlight and water evaporates faster by transpiration.

**82.** Which plants have leaves that are adapted to cold temperatures?

- a. Conifers such as spruce, fir, and pine have oval-shaped leaves with sunken stomata, helping to reduce water loss.
- b. Succulents such as aloes and agaves have waxy cuticles with sunken stomata, helping to reduce water loss.
- c. Conifers such as spruce, orchids, and pine have needle-shaped leaves with sunken stomata, helping to reduce water loss.
- d. Conifers such as spruce, fir, and pine have needle-shaped leaves with sunken stomata, helping to reduce water loss.

**83.** How is a leaf different from a leaflet?

- a. A leaf petiole attaches directly to the stem at a bud node, whereas a leaflet petiole is attached to the main petiole or the midrib, not the stem.
- b. A leaf has reticulate venation whereas leaflets show parallel venation.
- c. A leaf petiole attaches to the main petiole or the midrib, not the stem, whereas a leaflet petiole attaches directly to the stem at a bud node.
- d. A leaf has parallel venation whereas leaflets show reticulate venation.

**84.** Scientists on a new project to restore a damaged salt marsh are investigating several plants that could be introduced. Plant X is considered a possible candidate. Before the decision is made, the following data are

examined. Assume that the contribution of gravity and matric potential are negligible and can be ignored. Recall that the overall water potential for a system is represented by the equation:  $\Psi_{\text{system}} = \Psi_{\text{total}} = \Psi_s + \Psi_p + \Psi_g + \Psi_m$

overall  $\Psi$  of the soil: -2.1 MPa solute potential of the plant's cell contents: -0.12 MPa pressure potential ( $\Psi_p$ ) of the plant's cells: -2.3 MPa

Is Plant X a good candidate for introduction to the salt marsh?

- a. Yes, because the overall water potential of the plant is less negative than the water potential of the soil.
- b. No, because the overall water potential of the plant is less negative than the water potential of the soil.
- c. Yes, because the overall water potential of the plant is more negative than the water potential of the soil.
- d. No, because the overall water potential of the plant is more negative than the water potential of the soil.

**85.** What organs in humans are similar in function to the vascular tissues of vascular plants?

**86.** Apoptosis, or programmed cell death, is an important step in the development of xylem. How does apoptosis contribute to xylem development?

**87.** A florist decided to paint the leaves of poinsettia with a gold paint to embellish them. The plant soon wilted and the leaves drooped. What explains this damage?

- a. The paint clogged the stomata. Without photosynthesis, the plant could not pull water from the soil.
- b. The paint clogged the stomata. Without transpiration, the plant could not pull water from the soil.
- c. The paint clogged the hydathodes. Without transpiration, the plant could not pull water from the soil.
- d. The paint clogged the stomata. Without guttation, the plant could not pull water from the soil.

**88.** The process of bulk flow transports fluids in a plant. What are the two main bulk flow processes?

- a. Movement of water up the xylem and movement of solutes up and down the phloem
- b. Movement of water up the phloem and movement of solutes up and down the xylem.
- c. Movement of water up and down the xylem and movement of solutes up the phloem
- d. Movement of solutes up the xylem and movement of water up and down the phloem

**89.** During a severe drought, the soil becomes dry and its water potential decreases. Many plants will wilt in such an environment. Consider that the overall water potential for a system is represented by the equation:  $\Psi_{\text{system}} = \Psi_{\text{total}} = \Psi_s + \Psi_p + \Psi_g + \Psi_m$  What is one reason that plants are unable to draw water from the soil?

- a. The water potential of the soil becomes lower than the water potential of the plants.
- b. The water potential of the soil becomes lower than the solute potential of the plants.
- c. The water potential of the soil becomes higher than the water potential of the plants.
- d. The solute potential of the soil becomes lower than the water potential of the plants.

**90.** A botanist compares the number of stomata between two plants. One plant, a eucalyptus, has stomata equally distributed on both sides of the leaf. The other plant has most of its stomata on the underside of the leaf. What does the positioning of the stomata indicate about which leaf surfaces on the two plants receive light in their natural environment?

- a. The first plant receives light only on the upper surface of the leaves whereas the leaves of the second plant are equally exposed to sunlight.
- b. The first plant receives light only on the lower surface whereas the second plant receives light only on the upper surface.
- c. The first plant receives light only on the upper surface whereas the second plant receives light only on the lower surface.
- d. The first plant has leaves that are equally exposed to sunlight whereas the second plant receives light only on the upper surface.

**91.** In the Northern Hemisphere, owners and managers of plant nurseries have to plan lighting schedules for a long-day plant that will flower in February. What lighting periods and color will be most effective?

- a. Long periods of illumination with light enriched in the red range of the spectrum
- b. Short periods of illumination with light enriched in the red range of the spectrum
- c. Long periods of illumination with light enriched in the far-red range of the spectrum
- d. Short periods of illumination with light enriched in the far-red range of the spectrum

**92.** Why do plants that cannot detect gravity show stunted growth with tangled roots and trailing stems?

- a. Without gravitropism, both roots and seedlings would grow upward.
- b. Without gravitropism, roots would grow in all directions and seedlings would grow upward.
- c. Without gravitropism, roots would grow upward but seedlings would not grow upward toward the surface.
- d. Without gravitropism, roots would grow in all directions but seedlings would not grow upward toward the surface.

**93.** Storage facilities for fruits and vegetables are usually refrigerated and well ventilated. Why are these conditions advantageous?

- a. Refrigeration slows chemical reactions, including fruit ripening. Ventilation adds the ethylene gas that speeds up fruit maturation.
- b. Refrigeration slows chemical reactions, including fruit maturation. Ventilation removes the ethylene gas that reduces fruit ripening.
- c. Refrigeration slows chemical reactions, including fruit maturation. Ventilation removes the ethylene gas that speeds up fruit ripening.
- d. Refrigeration removes the ethylene gas that speeds up fruit ripening. Ventilation slows chemical reactions, including fruit maturation.

**94.** A Venus fly trap has a very low sensitivity threshold, yet it can tell the difference between the light touch of an insect and a drop of rainwater or wind. How can the Venus fly trap differentiate between a random stimulus and an actual prey?

- a. Hair-like appendages on the surface of the leaves respond to repeated contact.
- b. Hair-like appendages on the surface of the leaves respond to a single contact.
- c. Hair-like appendages on the surface of the leaves respond to chemical stimulus from the insect.
- d. Hair-like appendages on the surface of the leaves respond to the electrical stimulus from the insect.

**95.** Stomata close in response to bacterial infection. This response is a defense mechanism because it \_\_\_\_\_, and the hormone involved is \_\_\_\_\_.

- a. restricts the entry of O<sub>2</sub>; gibberellin
- b. restricts the entry of CO<sub>2</sub>; abscisic acid
- c. prevents further entry of pathogens; auxin
- d. prevents further entry of pathogens; abscisic acid

**96.** Why is shade avoidance an important survival mechanism for plants? Would you expect seeds with large energy storage to display as strong a response of shade avoidance as small seeds with limited reserves?

- a. A seedling growing in the shade of a mature plant will not have enough light to promote meristematic growth. A seed with large storage will be able to sustain growth until its seedling can reach enough light for photosynthesis.
- b. A seedling growing in the shade of a mature plant will not have enough light to promote photosynthesis. Small seeds with limited reserve will be able to sustain growth until seedlings can reach enough light for photosynthesis.
- c. A seedling growing in the shade of a mature plant will not have enough light to promote photosynthesis. A seed with large storage will be able to sustain growth until its seedling can reach enough light for photosynthesis.
- d. A seedling growing in the shade of a mature plant will not have enough light to promote respiration. Small seeds with limited reserve will be able to sustain growth until their seedlings can reach enough light for photosynthesis.

## TEST PREP FOR AP® COURSES

**97.** A plant has a measured pressure potential  $\Psi_p = 0.21\text{ MPa}$  and a solute potential  $\Psi_s = -3.50\text{ MPa}$ . The soil is saturated with water because it rained. How will the water move? After three months of dry weather, the soil has dried out. How will the water potential of the soil compare to the water potential measured immediately before the rain? How will the stomata respond to the change in weather?

- a. The water will move from the plant to the soil. Dry soil has a lower water potential than wet soil. Under drought conditions, the stomata close to conserve water and leaves may also be shed if the drought continues.
- b. The water will move from the soil to the plant. Dry soil has a higher water potential than wet soil. Under drought conditions, the stomata close to conserve water and leaves may also be shed if the drought continues.
- c. The water will move from the soil to the plant. Dry soil has a lower water potential than wet soil. Under drought conditions, the stomata open its pores wider in order to perform a better rate of transpiration.
- d. The water will move from the soil to the plant. Dry soil has a lower water potential than wet soil. Under drought conditions, the stomata close to conserve water and leaves may also be shed if the drought continues.

**98.**

| Transpiration rate versus temperature |     |    |    |     |    |
|---------------------------------------|-----|----|----|-----|----|
| Temperature (°C)                      | 20  | 23 | 27 | 28  | 30 |
| Transpiration rate (mmol/m² sec)      | 1.5 | 3  | 5  | 4.5 | 4  |

Plants lose water from their aboveground surfaces in the process of transpiration. Most of this water is lost from stomata. Excess loss of water has severe consequences and may be fatal for the plant. The table shows data collected on a sunny day. What is the best explanation for the transpiration rates leveling off and declining at temperature higher than 27°C?

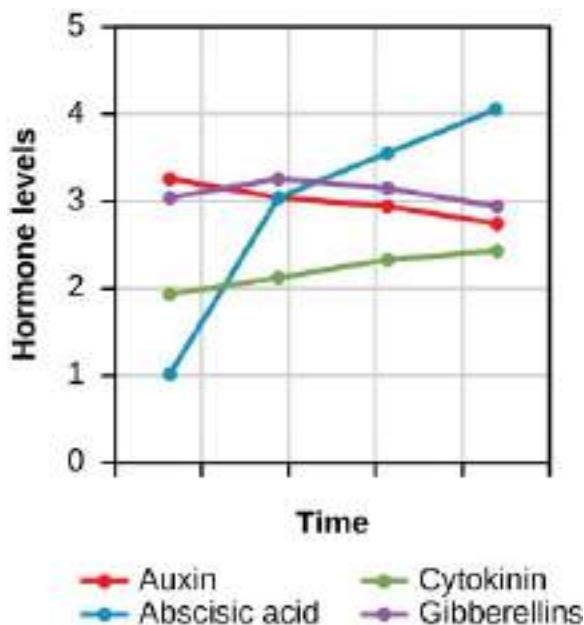

- a. The plant ran out of water.
- b. The plant needs less water as temperature increases, so transpiration slows down to limit water uptake by the roots.
- c. Stomata close to conserve water, slowing down transpiration.
- d. The amount of water in the leaves decreases at high temperature and less is available for evaporation.

**99.** Humidity is an environmental factor that affects transpiration rate. Which statement accurately explains the

shape of the curve obtained when increasing humidity is plotted against constant temperature to find the rate of transcription?

- Increasing humidity leads to reduced evaporation rates due to increased difference in water vapor pressure between leaf and atmosphere.
- Increasing humidity leads to reduced evaporation rates due to decreased difference in water vapor pressure between leaf and soil.
- Increasing humidity leads to reduced evaporation rates due to decreased difference in water vapor pressure between leaf and atmosphere.
- Increasing humidity leads to increased evaporation rates due to decreased difference in water vapor pressure between leaf and atmosphere.

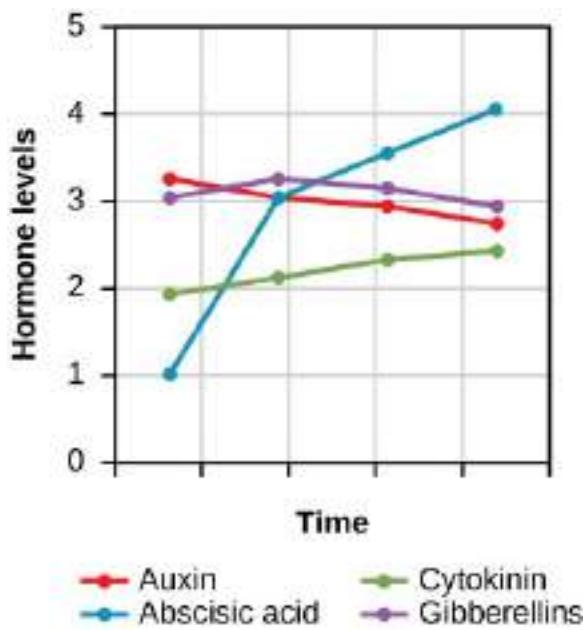

100.

Plants sense drought through the decrease in water potential in the ground. This graph shows concentrations of several hormones that were measured during a drought period and plotted versus time. According to the data in the graph, which hormone shows the strongest response to drought?

- auxin
- abscisic acid
- cytokinin
- gibberellins

101.

When drought conditions are forecast, fields are sprayed with a hormone that will promote a stress response. According to the graph, which hormone should be sprayed and why?

- Gibberellins, to promote plant growth before the plants are damaged
- Abscisic acid, to promote plant growth before the plants are damaged
- Abscisic acid, to promote protective response to drought before the plants are damaged.
- Gibberellins, to promote protective response to drought before the plants are damaged.

102.

|                        | Plate A | Plate B | Plate C |
|------------------------|---------|---------|---------|
| Percentage germination | 95%     | 50%     | 52%     |

Seeds were germinated in the dark on three plates. Plate A was irradiated with a short pulse of red light; plate B was irradiated with a short pulse of red light followed by a pulse of far-red light; and plate C was the control and was maintained in the dark. After three days, the plates were scored for percentage of germination, as shown in this table. What conclusion can be drawn from the experiment?

- a. Darkness inhibits germination.
- b. Red light promotes germination.
- c. Far-red light promotes germination.
- d. Germination is independent from light irradiation.

**103.**

|                        | Plate A | Plate B | Plate C | Plate D |
|------------------------|---------|---------|---------|---------|
| Percentage germination | 95%     | 50%     | 96%     | 52%     |

Seeds were germinated in the dark on three plates. Plate A was irradiated with a short pulse of red light; plate B was irradiated with a short pulse of red light followed immediately by a pulse of far-red light; plate D was irradiated by a short pulse of red light followed one hour later by a pulse of far-red light; and plate C was the control and was maintained in the dark. After three days, the plates were scored for percentage of germination, as shown in this table. What hypothesis do the results suggest about the mechanism of action of red light?

- a. Red light converts the phytochrome to its active form Pr which can be converted to the inactive form Pfr by far red light. After one hour, cascade of events initiated by Pfr has already begun promoting germination and hence, it cannot be reversed even by the pulse of far light.
- b. Red light converts the phytochrome to its active form Pfr, which can be converted to the inactive form Pr by far-red light. After one hour, cascade of events initiated by Pr has already begun promoting germination and, hence, it cannot be reversed even by the pulse of far light.
- c. Far red light converts the phytochrome to its active form Pfr, which can be converted to the inactive form Pr by red light. After one hour, the cascade of events initiated by Pr has already begun promoting germination and, hence, it cannot be reversed even by the pulse of far light.
- d. Red light converts the phytochrome to its active form Pfr which can be converted to the inactive form Pr by far red light. After one hour, the cascade of events initiated by Pfr has already begun promoting germination and, hence, it cannot be reversed even by the pulse of far light.

**104.** After branches of woody saplings were trimmed, half of the cuts were covered with a sealant and the other half were left untouched. The plants with sealed cuts fared much better after several weeks. What is the likely reason?

- a. The sealant stopped evaporation.
- b. The plants with sealed cuts grew new branches.
- c. The plants with unsealed cuts were infected by pathogens that entered through the cuts.
- d. The plants with unsealed cuts lost photosynthates through bleeding of sap.

**105.**

|                                             | Mutant plants ( $Ja^-$ ) | Normal plants ( $Ja^+$ ) |
|---------------------------------------------|--------------------------|--------------------------|
| Average size of wound from fungal infection | 10 mm                    | 4 mm                     |
| Weight of moth larvae                       | 80 mg                    | 55 mg                    |

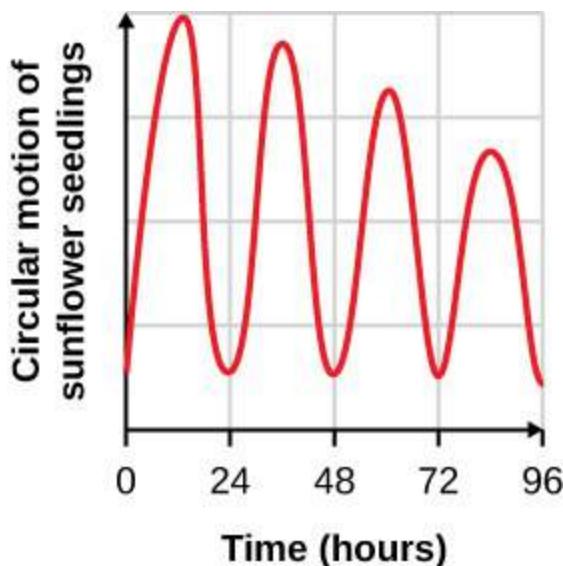

Jasmonate is produced in plants as a response to injury. Researchers compared the response to infection of mutant plants that were unable to produce jasmonate ( $Ja^-$ ) with the response of normal plants ( $Ja^+$ ) from the same species. Leaves were inoculated with spores from pathogenic molds. The size of the wounds was examined 48 hours after application. The plants were also infected with moths and the weight of the larvae was determined after 48 hours. This table shows the results. According to the results of the experiment, what conclusion can the researchers draw about the specificity of jasmonate protection?

- a. Jasmonate protects against infection from a variety of pathogens.
- b. Jasmonate protects against infection from one pathogen.
- c. Jasmonate cannot provide protection against infection.
- d. Jasmonate provides specific defense in winters and the defense is non-specific in summers.

**106.** In the Northern Hemisphere, a florist grows shrubs of the same species of woody plant under two different light schedules for three weeks. The first set is maintained under 15 hours of light and 9 hours of dark daily. The second set is maintained under 9 hours of light followed by 14 hours of dark daily. The first set of plants does not form flowers, but the second set of plants blooms. What can you conclude about these plants?

- a. This species of shrub does not flower if the day is short.
- b. They bloom early in the year (around February).
- c. They bloom mid-summer (around June).
- d. The critical dark period is 9 hours.

107.

Heliotropism is the description of a response to the light of the sun. Seedlings of sunflowers were exposed to sunlight for 15 days. Following the 15 days of exposure to sunlight, the seedlings were transferred to complete darkness and their movement was monitored. This graph plots the movement of the seedlings in the dark versus time. What conclusion can be drawn about the light dependence of the movement of sunflowers from the graph?

- a. The movement does require light once it is set but it will eventually slow down, suggesting that a “clock” molecule is degraded over time.
- b. The movement does not require light once it is set and it will keep showing this upward and downward trend in the same manner.
- c. The movement does not require light once it is set and it will eventually slow down, suggesting that a “clock” molecule never degrades.
- d. The movement does not require light once it is set and it will eventually slow down, suggesting that a “clock” molecule is degraded over time.

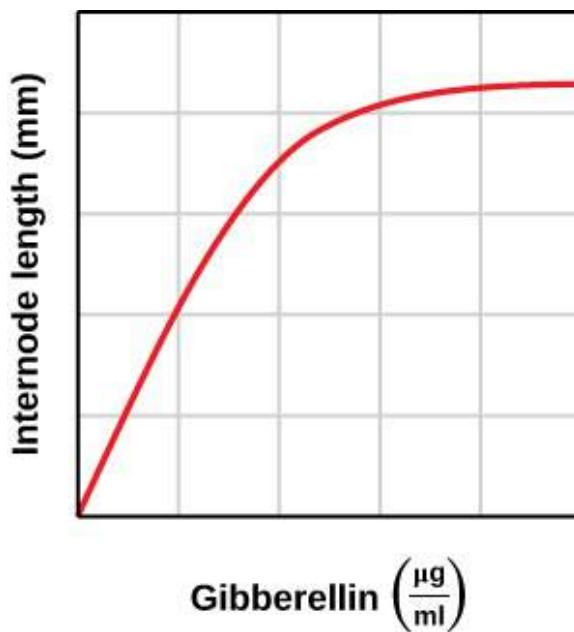

108.

|                                      | Dish A | Dish B |
|--------------------------------------|--------|--------|
| Germinated seeds                     | 12     | 20     |
| Green-leaved seedlings               | 0      | 15     |
| Yellow-leaved seedlings              | 12     | 5      |
| Mean length of stem below 1st leaves | 8 mm   | 3 mm   |

A student randomly chose 40 tobacco seeds of the same species from a packet. He placed 20 seeds on moist paper towels in each of two petri dishes. He wrapped dish A completely in an opaque cover to exclude all light. He did not wrap dish B. He placed the dishes equidistant from a light source set to a cycle of 14 hours of light and 10 hours of dark. All other conditions were the same for the two dishes. He examined the dishes after 7 days, and permanently removed the opaque cover from dish A. This table shows the student’s data. The most probable cause for the difference in mean stem length between plants in dish A and plants in dish B is \_\_\_\_.

- a. shortening of cells in the stem in response to the lack of light
- b. elongation of the stem in response to the lack of light
- c. enhancement of stem elongation by light
- d. genetic differences between the seeds

109.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**110.** The net photosynthetic production rate (NPP) is the difference between the rate of carbon fixation by photosynthesis (P) and the respiration rate (R). Each of these rates can be expressed in units of grams of carbon per day (gC/d). Vascular plants convert fixed carbon that is not released as carbon dioxide into biomass with a growth rate (G).

A. **Draw** areas within the box to represent the rates of growth (G) and respiration (R) to show the limit of each on the overall growth rate. The area of the box represents the rate of photosynthesis (P).

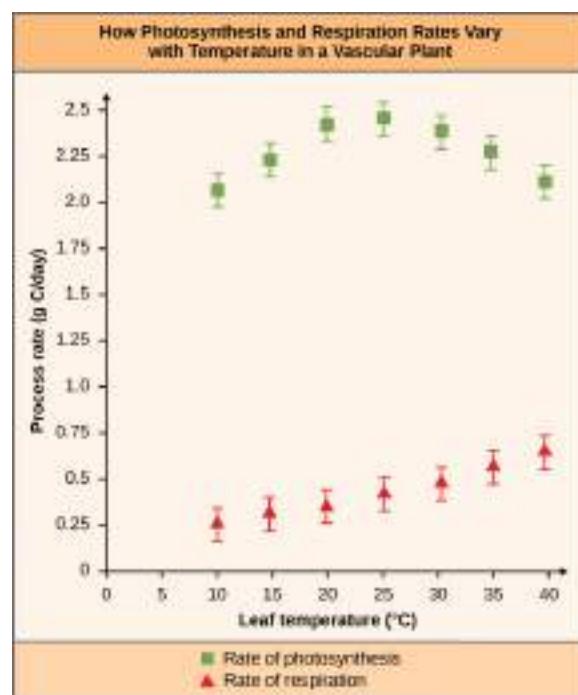

**Figure 23.42**

When the dependences on temperature of photosynthetic and respiration rates of a vascular plant are measured, the results depend on the species but have the general form shown in the figure. In these measurements, the temperature is maintained for several hours. The plant is then returned to 25 °C for several hours before the next set of measurements is made at a slightly higher temperature.

Groups of 20 seedlings from the same plant species were treated with gibberellins. Each group received a different concentration of hormone. The seedlings were grown under the same environmental conditions. After 15 days of growth, the internode distances between the first and second sets of leaves were measured in each group of seedlings. On this graph, the mean internode distance for each group is plotted against the concentration of gibberellins that the group received. According to the results, why is this effect of gibberellins on internode length used in agriculture to spray grapes with oversized fruit?

- to lengthen the internode distance and accommodate larger fruit
- to shorten the internode distance and accommodate larger fruit
- to lengthen the internode distance and accommodate more flowers
- to shorten the internode distance and accommodate smaller fruit

**Figure 23.43**

B. **Evaluate** these data to approximately predict the quantitative effect on the NPP and free energy availability in a deciduous forest ecosystem with a 3–5 °C increase in temperature. This is the expected temperature increase by the year 2100. Assume the current average summer temperature of the forest ecosystem is 25 °C.

In other experiments, rather than returning the plants to 25 °C, the plant is grown for several days at a constant higher

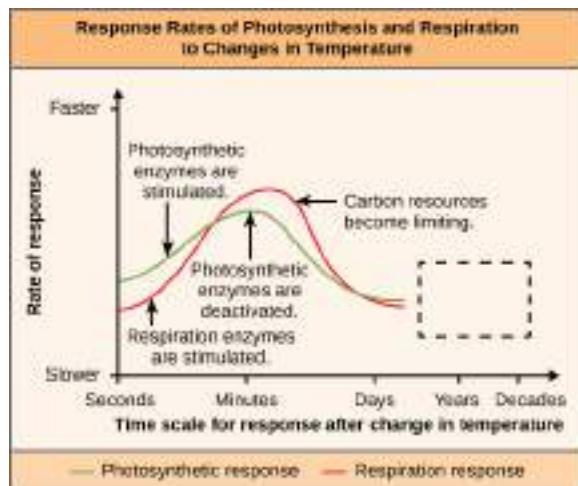

temperature. Under these conditions, the maximum photosynthetic rate shifts towards the temperature of the new growing conditions. However, there is little change in the temperature dependence of respiration rate. This is referred to as temperature acclimation, an effect of great importance to predictions of future climate change.

**C. Pose two scientific questions** whose pursuit could lead to either an improved understanding of the mechanisms of temperature acclimation or improvements in models of atmospheric carbon dioxide concentrations that control temperature.

According to the graph, growth is predicted to increase when acclimation is taken into account and the average temperature increases of Earth's surface increases by the expected 3-5°C. Growth enhancement may be reduced, however, if respiration increases more rapidly than photosynthesis, particularly under periods of drought and stress. Thus, climate warming may result in positive, negative, or potentially no effect on the free energy availability in forest ecosystems.

D. In the figure below, the response to temperate change in terms of the rates of photosynthesis and respiration are sketched as a function of time from the very short-term (seconds) to the longer-term (decades) changes.

Acclimation in the laboratory occurs in days. **Analyze** the graphs; in the box bounded by a dashed line, sketch curves for responses of both processes beyond the acclimation observed in the laboratory that are consistent with a neutral effect on free energy availability and provide your reasoning.

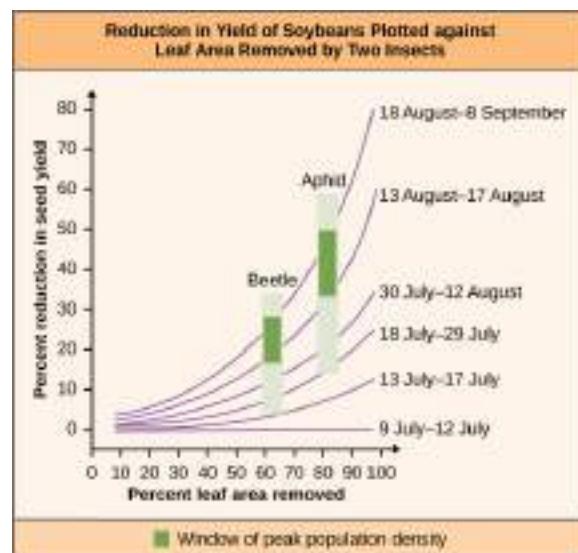

**Figure 23.44**

E. **Analyze** the long-term effect of a rate of respiration that exceeds the rate of photosynthesis in terms of dynamic homeostasis.

**111.** A disruption of dynamic homeostasis in the relationship between vascular plants and insects is occurring as global climate changes. The reduction in the yield of soybeans is plotted against leaf area removed by two insects, beetles and aphids. Soybean blooms begin to

develop in the week of 13 July. Prior to that time, there is no effect of leaf removal on yield, even with complete loss of leaves. In the week of 18 August, plants are beginning to form seeds, and loss of leaves can be devastating.

**Figure 23.45**

A. One observed effect of climate change is the shift toward earlier development in many insects. Quantitatively **describe** the worst possible consequences for yield, assuming plant developmental timing is not altered by warming temperatures, if the peak abundance of Japanese beetles is shifted from 18 July to 13 July, and 80% of leaf area is lost.

The expression of genes involved in seed development is temperature dependent, unlike the scenario suggested in part A. More than 90% of soybean seeds planted in 2015 in the soybean-corn ecosystem of the central United States are the herbicide-resistant, genetically modified "Roundup Ready" variety. The seed has a patented genome. It produces seeds that are sterile and must be purchased each spring from the patent holder.

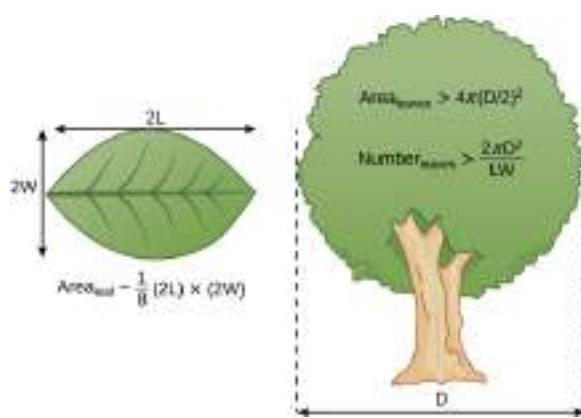

B. **Predict** how the use of Roundup Ready seeds affects the selection of expression regulated in response to increasing temperature.

Roundup is an herbicide whose active chemical component is glyphosate. This molecule disrupts the synthesis of phenylalanine, tyrosine, and tryptophan. By inserting a gene from *Agrobacterium*, a Roundup Ready seed can synthesize these amino acids in the presence of the herbicide.

C. **Pose two scientific questions** that must be considered to estimate the long-term effectiveness of this strategy for weed management.

**112.** By increasing the photosynthetic surface area, a plant increases the rate of capture of free energy. For every carbon atom fixed into carbohydrates, between 200 and 400 water molecules are released through stomata to the

atmosphere. A simple geometric model can be used to estimate the minimum number of leaves on a tree, as shown.

**Figure 23.46**

A. **Identify and justify the data** needed to describe the relationship between the free energy captured and the water transpired by a tree with dimensions D, L, and W. Use these data to **construct a mathematical model** of the relationship between transpiration rate and the rate of free energy captured when a single carbon atom is fixed.

The diversity of vascular plants decreases with increasing latitude. Equatorial ecosystems have greater plant diversity than do ecosystems further south or north. One of several explanations offered to account for this observation is the energy-equivalence model—as free energy increases, population size increases. As population size increases, mutations increase. One bit of evidence for the energy-equivalence model is the correlation of family-level diversity with actual evapotranspiration, the sum of water transferred by both transpiration and evaporation of surface water. This property is reported in mm of water per square meter of surface area.

B. **Explain** the relationship between free energy exchange and latitude that is the basis of the energy-equivalence model.

Shared ancestry is indicated by taxonomic classification in which a family of organisms contains many genera, and within each genus there are many species. A survey of tree flora (Latham and Ricklefs, *Oikos*, 67, 1993) at comparable latitudes in a temperate eastern Asia forest ecosystem (729 species in 177 genera and 67 families) and an eastern North America forest ecosystem (253 species in 90 genera and 46 families) had no species in common, but there were 20 common genera and 40 common families. Actual evapotranspiration for the two ecosystems are  $850 \pm 200$  mm (eastern North America) and  $730 \pm 160$  mm (eastern Asia).

C. **Analyze** these data to test the validity of the energy-equivalence model.

**113.** The evolution of vascular plants followed the colonization of terrestrial habitats by ancestors of

*Chlorophyta*, green algae, during the Devonian period (which began about 400 million years ago). The three most significant structural innovations in that process are responses to selection through the availability of water resources: 1) the cuticle, a waxy covering of the epidermis that retains water; 2) stomata, openings that penetrate the cuticle through which water and carbon dioxide are transported; and 3) a vascular system, plant tissues through which water moves.

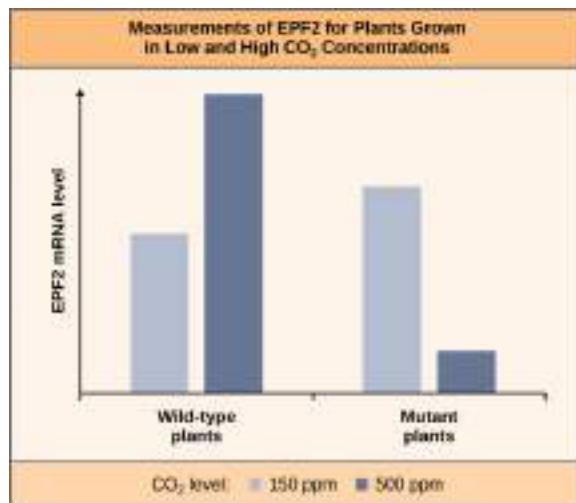

Measurements of gases trapped in ice cores provide atmospheric concentrations of the distant, as well as the recent, past. Life must adapt to changes in the environment. Woodward examined samples from the Cambridge herbarium of several trees (*Nature*, 327, 1987) to determine the stomatal index (percentage of epidermal cells that contain a stoma). In 1720, when the herbarium samples were collected, the carbon dioxide concentration in Earth's atmosphere was 225 ppm. In the year of the study, 1987, it was 340 ppm (it is 370 ppm in 2016). The following table presents some of Woodward's reported results.

| Tree Genus     | CO <sub>2</sub> (ppm) | Stomatal Index (%) |
|----------------|-----------------------|--------------------|
| <i>Acer</i>    | 225                   | $14.9 \pm 0.8$     |
|                | 340                   | $6.7 \pm 1.1$      |
| <i>Quercus</i> | 225                   | $17.4 \pm 1.1$     |
|                | 340                   | $9.6 \pm 1$        |
| <i>Rumex</i>   | 225                   | $15.5 \pm 0.7$     |
|                | 340                   | $11.8 \pm 0.9$     |

**Table 23.1**

Teng and co-workers (PLOS ONE, 2009) followed the dependence of *Arabidopsis*, a member of the *Brassica* family of vascular plants, grown under a range of elevated CO<sub>2</sub> concentrations for 15 generations. They found elevated stomatal densities for each generation that were not heritable.

Engineer and co-workers (*Nature*, 513, 2014) discovered a mutant *Arabidopsis* in which stomatal density increases as CO<sub>2</sub> concentration increases. Measurements of a component of the set of mRNA molecules for epidermal patterning factor 2 (EPF2), responsible for stomatal density, are shown for plants grown in low and high CO<sub>2</sub> concentrations.

**Figure 23.47**

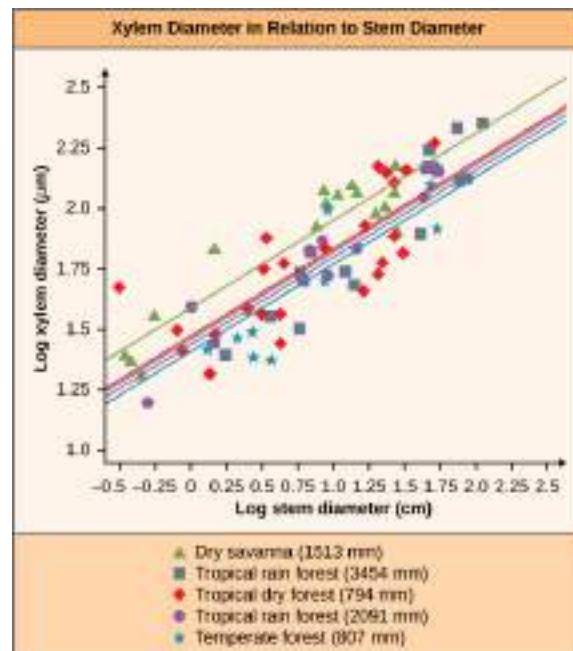

A. **Analyze** these data in terms of the likelihood that the effect of carbon dioxide concentration on stomatal density involves negative feedback at the level of i) translation, ii) post-transcription, or iii) changes in genotype.

B. Changes in precipitation patterns are expected to accompany an increase in atmospheric carbon dioxide. **Predict** the effect on a forest where trees that have matured over decades are suddenly under drought stress. **Justify** your prediction in terms of positive or negative feedback where stomatal density is high and a drought occurs.

In a favorable environment, trees continue to accumulate biomass and increase in height until the flow rate of water through the xylem (plant vascular tissue that transports water and minerals from roots to shoots) is no longer sufficient to support the negative water potential at the interface between root and soil. Fluid dynamic models predict that increasing the diameter,  $d$ , of the xylem greatly increases the rate of flow of water, leading to greater productivity when water is abundant. Under conditions of drought stress, the water potential is reduced, and an air bubble can disrupt the flow of water in that vessel entirely. A larger stem diameter permits a larger number of small vessels.

C. **Describe a model** of the evolution of xylem in trees in terms of selection under conditions of unlimited and limited water resources.

Olson and Rosell (*New Phytologist*, 197, 2013) investigated the question of whether xylem diameter was determined by water availability or by plant height and, consequently, stem diameter. A summary of their data is shown with lines of best fit through data with the corresponding color.

**Figure 23.48**

D. **Analyze** these data and summarize the pattern that addresses their question. Note: As  $x$  increases,  $\log(x)$  increases.

114. Like the animal intestine, the organ system principally responsible for nutrient and water uptake, the plant root system, is home to a microbiome upon which the host depends. One important role for the root microbiome is innate immunity. Wheat take-all is a disease caused by the fungus *Gaeumannomyces graminis* that attacks plant roots and blocks root water channels. When a major outbreak occurs in a wheat field, susceptibility remains high in the following year. But after four to six continued crops of wheat in the same field, susceptibility to the disease declines. This resistance can be transferred with the soil. Burning the soil surface or rotation with another crop returns susceptibility to the next wheat crop. The *Fusarium* (a fungus) wilt disease of strawberries and potato scab caused by *Streptomyces scabies* (a bacteria) show a similar disease progression and transferability of resistance (Weller, *Ann. Rev. Plant Pathol.*, 26, 1988).

A. Plants, like animals, have immune defenses that may involve cooperative interactions between organisms.

**Describe a model** of immune response that accounts for these behaviors.

In plants, the first line of defense is the cell wall. Animal cells lack this protective barrier. Adaptive immunity of vertebrates to pathogens uses specific defenses that are transportable within the organism, such as T-cells, and retains information about earlier infections, such as T-cell receptors. Unlike adaptive immunity, the innate responses of plants are much less effective in defending against necrotrophic (colonizing dead tissue) than against biotrophic (infecting living tissue) pathogens. In animal

tissue, the response to infection is inflammation, the recruitment of resources to protect the tissue. In plant tissue, the response is apoptosis.

B. **Describe** contrasting models of defense strategies for

plants and animals that express each of these differences in terms of these strategies: cell boundary, immunological memory, and tissue repair.

# 24 | THE ANIMAL BODY: BASIC FORM AND FUNCTION

**Figure 24.1** An arctic fox is a complex animal, well adapted to its environment. It changes coat color with the seasons, and has longer fur in winter to trap heat. (credit: modification of work by Keith Morehouse, USFWS)

## Chapter Outline

- 24.1: Animal Form and Function**
- 24.2: Animal Primary Tissues**
- 24.3: Homeostasis**

## Introduction

The structures of animals consist of primary tissues that make up more complex organs and organ systems. Homeostasis allows an animal to maintain a balance between its internal and external environments.

The arctic fox is an example of a complex animal that is well adapted to its environment and illustrates the relationships between an animal's form and function. According to researchers, animals living millions of years ago in the Himalayan Mountains of Tibet are ancestors to many of today's cold-adapted animals. For example, a type of Tibetan fox from 3–5 million years ago is the ancestor to the arctic fox.<sup>11</sup> More about this research can be found at the **Science Daily website** (<http://openstaxcollege.org/l/32arcticfox>) .

## 24.1 | Animal Form and Function

In this section, you will explore the following questions:

- What are the various types of body plans that occur in animals?
- What are the limits on animal size and shape?
- How do bioenergetics relate to body size, levels of activity, and the environment?

### Connection for AP® Courses

As you have learned, specialized cells in the animal body are organized into tissues, organs, and organ systems, which efficiently localize functions, such as the digestion of food and the elimination of wastes. As we explore the information in this section, our primary focus is **homeostasis**—the ability to maintain dynamic equilibrium around a **set point**. Animals need to maintain their “normal” internal environments while also responding to external environmental changes.

In our study of biology thus far, we have seen numerous examples of structure-function relationships, and the design of the animal body is no exception. Specialization in multicellular animals contributes to efficiency in cell processes. For example, animals must be able to procure nutrients and eliminate wastes, and cells that line the small intestine allow for diffusion. Furthermore, the relationship between metabolic rate and body mass is typically an inverse one: The smaller the animal, the higher its metabolism, with mice having a higher metabolic rate than, for example, elephants. Because mice have a greater surface area-to-volume ratio for their mass than larger animals, they lose heat at a faster rate and, consequently, require more energy to maintain constant body temperature.

Speaking of temperature, we learned that the body temperature of ectothermic animals varies according to environmental temperatures. When snakes need to warm up, they bask in the sun; when they need to cool down, they go into the shade. Other animals, including mice, kangaroos and humans, are endothermic because they are able to maintain a fairly constant internal body temperature despite environmental temperatures; for example, shivering generates heat, whereas sweating returns our body temperature to its normal set point of 37°C. We will explore the control of these responses in more detail in the **Homeostasis** section.

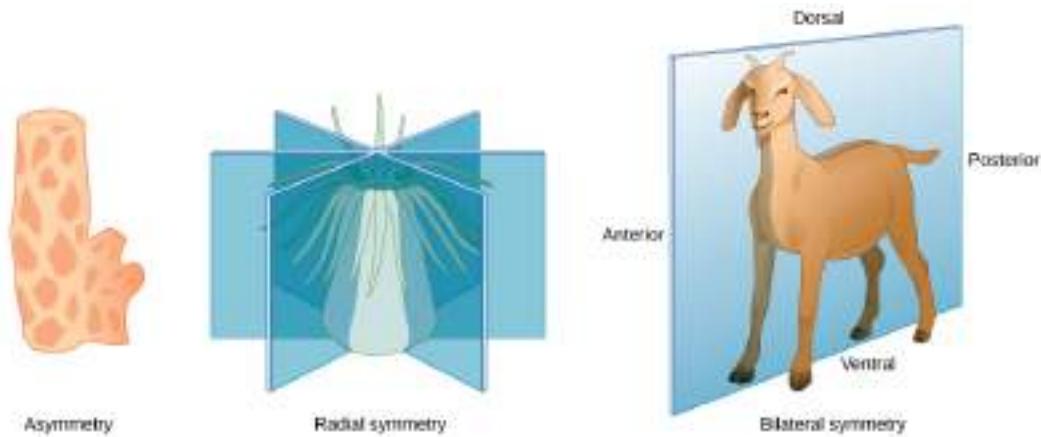

The information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven Science Practices.

|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Big Idea 2</b>                 | Biological systems utilize free energy and molecular building blocks to grow, to reproduce, and to maintain dynamic homeostasis.                                                                              |
| <b>Enduring Understanding 2.A</b> | Growth, reproduction and maintenance of living systems require free energy and matter.                                                                                                                        |
| <b>Essential Knowledge</b>        | <b>2.A.1</b> All living systems require constant input of free energy.                                                                                                                                        |
| <b>Science Practice</b>           | <b>6.2</b> The student can construct explanations of phenomena based on evidence produced through scientific practices.                                                                                       |
| <b>Learning Objective</b>         | <b>2.1</b> The student is able to explain how biological systems use free energy based on empirical data that all organisms require constant energy input to maintain organization, to grow and to reproduce. |
| <b>Essential Knowledge</b>        | <b>2.A.1</b> All living systems require constant input of free energy.                                                                                                                                        |
| <b>Science Practice</b>           | <b>6.1:</b> The student can justify claims with evidence.                                                                                                                                                     |

|                            |                                                                                                                                                                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Learning Objective</b>  | 2.2 The student is able to justify a scientific claim that free energy is required for living systems to maintain organization, to grow or to reproduce, but that multiple strategies exist in different living systems. |
| <b>Essential Knowledge</b> | 2.A.1 All living systems require constant input of free energy.                                                                                                                                                          |
| <b>Science Practice</b>    | 4.2 The student can design a plan for collecting data to answer a particular scientific question.                                                                                                                        |
| <b>Learning Objective</b>  | 2.35 The student is able to design a plan for collecting data to support the scientific claim that timing and coordination of physiological events involve regulation                                                    |
| <b>Essential Knowledge</b> | 2.A.1 All living systems require constant input of free energy.                                                                                                                                                          |
| <b>Science Practice</b>    | 6.1 The student can justify claims with evidence.                                                                                                                                                                        |
| <b>Learning Objective</b>  | 2.36 The student is able to justify scientific claims with evidence to show how timing and coordination of physiological events involve regulation.                                                                      |
| <b>Essential Knowledge</b> | 2.A.1 All living systems require constant input of free energy.                                                                                                                                                          |
| <b>Science Practice</b>    | 7.2 The student can connect concepts in and across domain(s) to generalize or extrapolate in and/or across enduring understandings and/or big ideas.                                                                     |
| <b>Learning Objective</b>  | 2.37 The student is able to connect concepts that describe mechanisms that regulate the timing and coordination of physiological events.                                                                                 |

Animals vary in form and function. From a sponge to a worm to a goat, an organism has a distinct body plan that limits its size and shape. Animals' bodies are also designed to interact with their environments, whether in the deep sea, a rainforest canopy, or the desert. Therefore, a large amount of information about the structure of an organism's body (anatomy) and the function of its cells, tissues and organs (physiology) can be learned by studying that organism's environment.

## Body Plans

**Figure 24.2** Animals exhibit different types of body symmetry. The sponge is asymmetrical, the sea anemone has radial symmetry, and the goat has bilateral symmetry.

Animal body plans follow set patterns related to symmetry. They are asymmetrical, radial, or bilateral in form as illustrated in **Figure 24.2**. **Asymmetrical** animals are animals with no pattern or symmetry; an example of an asymmetrical animal is a sponge. Radial symmetry, as illustrated in **Figure 24.2**, describes when an animal has an up-and-down orientation: any plane cut along its longitudinal axis through the organism produces equal halves, but not a definite right or left side. This plan is found mostly in aquatic animals, especially organisms that attach themselves to a base, like a rock or a boat, and extract their food from the surrounding water as it flows around the organism. Bilateral symmetry is illustrated in the same

figure by a goat. The goat also has an upper and lower component to it, but a plane cut from front to back separates the animal into definite right and left sides. Additional terms used when describing positions in the body are anterior (front), posterior (rear), dorsal (toward the back), and ventral (toward the stomach). Bilateral symmetry is found in both land-based and aquatic animals; it enables a high level of mobility.

## Limits on Animal Size and Shape

Animals with bilateral symmetry that live in water tend to have a **fusiform** shape: this is a tubular shaped body that is tapered at both ends. This shape decreases the drag on the body as it moves through water and allows the animal to swim at high speeds. **Table 24.1** lists the maximum speed of various animals. Certain types of sharks can swim at fifty kilometers an hour and some dolphins at 32 to 40 kilometers per hour. Land animals frequently travel faster, although the tortoise and snail are significantly slower than cheetahs. Another difference in the adaptations of aquatic and land-dwelling organisms is that aquatic organisms are constrained in shape by the forces of drag in the water since water has higher viscosity than air. On the other hand, land-dwelling organisms are constrained mainly by gravity, and drag is relatively unimportant. For example, most adaptations in birds are for gravity not for drag.

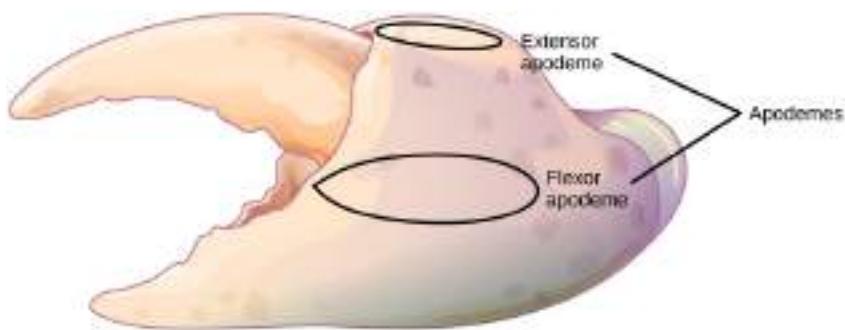

**Maximum Speed of Assorted Land Marine Animals**

| Animal              | Speed (kmh) | Speed (mph) |
|---------------------|-------------|-------------|
| Cheetah             | 113         | 70          |
| Quarter horse       | 77          | 48          |
| Fox                 | 68          | 42          |
| Shortfin mako shark | 50          | 31          |
| Domestic house cat  | 48          | 30          |
| Human               | 45          | 28          |
| Dolphin             | 32–40       | 20–25       |
| Mouse               | 13          | 8           |
| Snail               | 0.05        | 0.03        |

**Table 24.1**

Most animals have an exoskeleton, including insects, spiders, scorpions, horseshoe crabs, centipedes, and crustaceans. Scientists estimate that, of insects alone, there are over 30 million species on our planet. The exoskeleton is a hard covering or shell that provides benefits to the animal, such as protection against damage from predators and from water loss (for land animals); it also provides for the attachments of muscles.

As the tough and resistant outer cover of an arthropod, the exoskeleton may be constructed of a tough polymer such as chitin and is often biomineralized with materials such as calcium carbonate. This is fused to the animal's epidermis. Ingrowths of the exoskeleton, called **apodemes**, function as attachment sites for muscles, similar to tendons in more advanced animals (**Figure 24.3**). In order to grow, the animal must first synthesize a new exoskeleton underneath the old one and then shed or molt the original covering. This limits the animal's ability to grow continually, and may limit the individual's ability to mature if molting does not occur at the proper time. The thickness of the exoskeleton must be increased significantly to accommodate any increase in weight. It is estimated that a doubling of body size increases body weight by a factor of eight. The increasing thickness of the chitin necessary to support this weight limits most animals with an exoskeleton to a relatively small size. The same principles apply to endoskeletons, but they are more efficient because muscles are attached on the outside, making it easier to compensate for increased mass.

**Figure 24.3** Apodemes are ingrowths on arthropod exoskeletons to which muscles attach. The apodemes on this crab leg are located above and below the fulcrum of the claw. Contraction of muscles attached to the apodemes pulls the claw closed.

An animal with an endoskeleton has its size determined by the amount of skeletal system it needs in order to support the other tissues and the amount of muscle it needs for movement. As the body size increases, both bone and muscle mass increase. The speed achievable by the animal is a balance between its overall size and the bone and muscle that provide support and movement.

## Limiting Effects of Diffusion on Size and Development

The exchange of nutrients and wastes between a cell and its watery environment occurs through the process of diffusion. All living cells are bathed in liquid, whether they are in a single-celled organism or a multicellular one. Diffusion is effective over a specific distance and limits the size that an individual cell can attain. If a cell is a single-celled microorganism, such as an amoeba, it can satisfy all of its nutrient and waste needs through diffusion. If the cell is too large, then diffusion is ineffective and the center of the cell does not receive adequate nutrients nor is it able to effectively dispel its waste.

An important concept in understanding how efficient diffusion is as a means of transport is the surface area to volume ratio. Recall that any three-dimensional object has a surface area and volume; the ratio of these two quantities is the surface-to-volume ratio. Consider a cell shaped like a perfect sphere: it has a surface area of  $4\pi r^2$ , and a volume of  $(4/3)\pi r^3$ . The surface-to-volume ratio of a sphere is  $3/r$ ; as the cell gets bigger, its surface area to volume ratio decreases, making diffusion less efficient. The larger the size of the sphere, or animal, the less surface area for diffusion it possesses.

The solution to producing larger organisms is for them to become multicellular. Specialization occurs in complex organisms, allowing cells to become more efficient at doing fewer tasks. For example, circulatory systems bring nutrients and remove waste, while respiratory systems provide oxygen for the cells and remove carbon dioxide from them. Other organ systems have developed further specialization of cells and tissues and efficiently control body functions. Moreover, surface area-to-volume ratio applies to other areas of animal development, such as the relationship between muscle mass and cross-sectional surface area in supporting skeletons, and in the relationship between muscle mass and the generation of dissipation of heat.

Visit **this interactive site** (<http://openstaxcollege.org/l/nanoscropy>) to see an entire animal (a zebrafish embryo) at the cellular and sub-cellular level. Use the zoom and navigation functions for a virtual nanoscopy exploration.

Zebrafish have bilateral symmetry. What does that mean?

- Bilaterally symmetric means that a plane cut from the front to back of the organism produces distinct left and right sides that are mirror images of each other.
- Bilaterally symmetric means that a plane cut from the top to the bottom of the organism produces distinct left and right sides that are mirror images of each other.
- Bilaterally symmetric means that a plane cut from the front to back of the organism produces distinct left and right sides that are not mirror images of each other.
- Bilaterally symmetric means that a plane cut along its longitudinal axis produces equal halves, but not definite right or left sides.

## Animal Bioenergetics

All animals must obtain their energy from food they ingest or absorb. These nutrients are converted to adenosine triphosphate (ATP) for short-term storage and use by all cells. Some animals store energy for slightly longer times as glycogen, and others store energy for much longer times in the form of triglycerides housed in specialized adipose tissues. No energy system is one hundred percent efficient, and an animal's metabolism produces waste energy in the form of heat. If an animal can conserve that heat and maintain a relatively constant body temperature, it is classified as a warm-blooded animal and called an **endotherm**. The insulation used to conserve the body heat comes in the forms of fur, fat, or feathers. The absence of insulation in **ectothermic** animals increases their dependence on the environment for body heat.

The amount of energy expended by an animal over a specific time is called its metabolic rate. The rate is measured variously in joules, calories, or kilocalories (1000 calories). Carbohydrates and proteins contain about 4.5 to 5 kcal/g, and fat contains about 9 kcal/g. Metabolic rate is estimated as the **basal metabolic rate (BMR)** in endothermic animals at rest and as the **standard metabolic rate (SMR)** in ectotherms. Human males have a BMR of 1600 to 1800 kcal/day, and human females have a BMR of 1300 to 1500 kcal/day. Even with insulation, endothermal animals require extensive amounts of energy to maintain a constant body temperature. An ectotherm such as an alligator has an SMR of 60 kcal/day.

### **Energy Requirements Related to Body Size**

Smaller endothermic animals have a greater surface area for their mass than larger ones (Figure 24.4). Therefore, smaller animals lose heat at a faster rate than larger animals and require more energy to maintain a constant internal temperature. This results in a smaller endothermic animal having a higher BMR, per body weight, than a larger endothermic animal.

|                |                                                    |                                                   |
|----------------|----------------------------------------------------|---------------------------------------------------|
| Species        |                                                    |                                                   |
| Mass           | 35 g                                               | 4,500,000 g                                       |
| Metabolic rate | 880 mm <sup>3</sup> O <sub>2</sub> /g body mass/hr | 75 mm <sup>3</sup> O <sub>2</sub> /g body mass/hr |

**Figure 24.4** The mouse has a much higher metabolic rate than the elephant. (credit “mouse”: modification of work by Magnus Kjaergaard; credit “elephant”: modification of work by “TheLizardQueen”/Flickr)

### Energy Requirements Related to Levels of Activity

The more active an animal is, the more energy is needed to maintain that activity, and the higher its BMR or SMR. The average daily rate of energy consumption is about two to four times an animal’s BMR or SMR. Humans are more sedentary than most animals and have an average daily rate of only 1.5 times the BMR. The diet of an endothermic animal is determined by its BMR. For example: the type of grasses, leaves, or shrubs that an herbivore eats affects the number of calories that it takes in. The relative caloric content of herbivore foods, in descending order, is tall grasses > legumes > short grasses > forbs (any broad-leaved plant, not a grass) > subshrubs > annuals/biennials.

### Energy Requirements Related to Environment

Animals adapt to extremes of temperature or food availability through torpor. **Torpor** is a process that leads to a decrease in activity and metabolism and allows animals to survive adverse conditions. Torpor can be used by animals for long periods, such as entering a state of **hibernation** during the winter months, in which case it enables them to maintain a reduced body temperature. During hibernation, ground squirrels can achieve an abdominal temperature of 0° C (32° F), while a bear’s internal temperature is maintained higher at about 37° C (99° F).

If torpor occurs during the summer months with high temperatures and little water, it is called **estivation**. Some desert animals use this to survive the harshest months of the year. Torpor can occur on a daily basis; this is seen in bats and hummingbirds. While endothermy is limited in smaller animals by surface to volume ratio, some organisms can be smaller and still be endotherms because they employ daily torpor during the part of the day that is coldest. This allows them to conserve energy during the colder parts of the day, when they consume more energy to maintain their body temperature.

## science practices CONNECTION for AP® Courses

### Activity

Read about how scientists developed a method using today’s technology to collect data on heart rates in hibernating bears at [this website](http://openstaxcollege.org/l/32bears) (<http://openstaxcollege.org/l/32bears>) . Design an experiment that would allow you to collect body temperature and heart rate at the same time. Discuss how combining data on body temperature with heart rate can give you information on the animal’s overall metabolism.

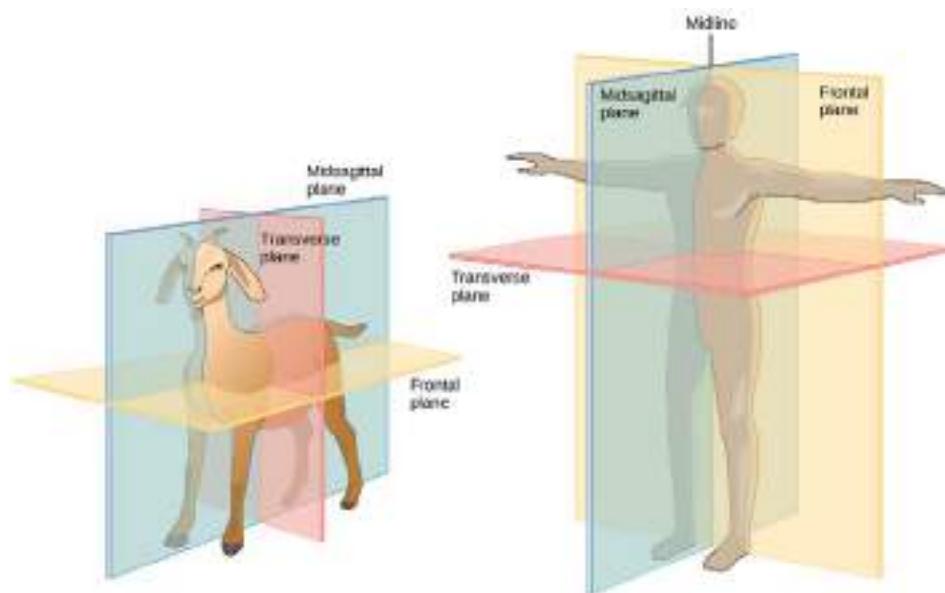

### Think About It

- Small mammals, such as squirrels need to eat at least once a week during hibernation. Why is it impossible for them to go through the entire winter without eating, as bears do? Also, why must smaller mammals, like squirrels, store food for the winter while larger mammals, like bears, do not?
- Hummingbirds lower their metabolic rate and body temperature at night, an example of torpor. What advantage does torpor provide hummingbirds on a nightly basis? Think about the high metabolic rates of hummingbirds.

## Animal Body Planes and Cavities

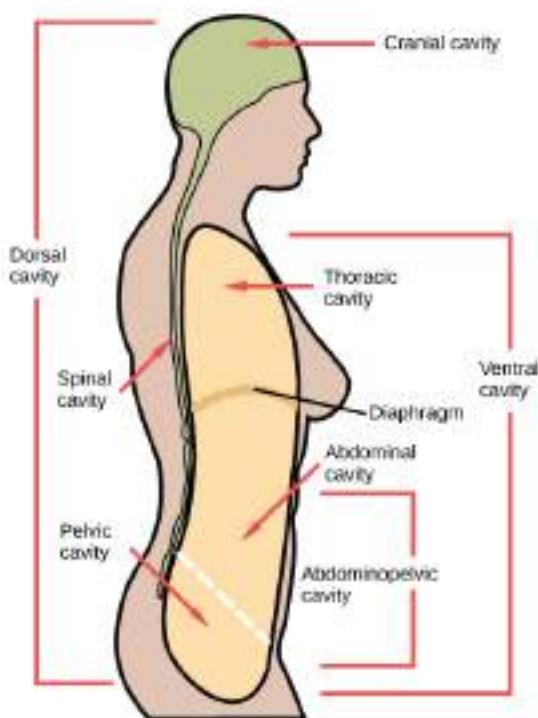

A standing vertebrate animal can be divided by several planes. A **sagittal plane** divides the body into right and left portions.

A **midsagittal plane** divides the body exactly in the middle, making two equal right and left halves. A **frontal plane** (also called a coronal plane) separates the belly (ventral) or stomach from the back (dorsal). A **transverse plane** (or, horizontal plane) is perpendicular to the sagittal planes and the long axis of the body. This is sometimes called a cross section, and, if the transverse cut is at an angle, it is called an oblique plane. **Figure 24.5** illustrates these planes on a goat (a four-legged animal) and a human being.

**Figure 24.5** Shown are the planes of a quadruped goat and a bipedal human. The midsagittal plane divides the body exactly in half, into right and left portions. The frontal plane divides the front and back, and the transverse plane divides the body into upper and lower portions.

Vertebrate animals have a number of defined body cavities, as illustrated in **Figure 24.6**. Two of these are major cavities that contain smaller cavities within them. The **dorsal cavity** contains the cranial and the vertebral (or spinal) cavities. The **ventral cavity** contains the thoracic cavity, which in turn contains the pleural cavity around the lungs and the pericardial cavity, which surrounds the heart. The ventral cavity also contains the abdominopelvic cavity, which can be separated into the abdominal and the pelvic cavities.

**Figure 24.6** Vertebrate animals have two major body cavities. The dorsal cavity, indicated in green, contains the cranial and the spinal cavity. The ventral cavity, indicated in yellow, contains the thoracic cavity and the abdominopelvic cavity. The thoracic cavity is separated from the abdominopelvic cavity by the diaphragm. The thoracic cavity is separated into the abdominal cavity and the pelvic cavity by an imaginary line parallel to the pelvis bones. (credit: modification of work by NCI)

## career CONNECTION

### Physical Anthropologist

Physical anthropologists study the adaption, variability, and evolution of human beings, plus their living and fossil relatives. They can work in a variety of settings, although most will have an academic appointment at a university, usually in an anthropology department or a biology, genetics, or zoology department.

Non-academic positions are available in the automotive and aerospace industries where the focus is on human size, shape, and anatomy. Research by these professionals might range from studies of how the human body reacts to car crashes to exploring how to make seats more comfortable. Other non-academic positions can be obtained in museums of natural history, anthropology, archaeology, or science and technology. These positions involve educating students from grade school through graduate school. Physical anthropologists serve as education coordinators, collection managers, writers for museum publications, and as administrators. Zoos employ these professionals, especially if they have an expertise in primate biology; they work in collection management and captive breeding programs for endangered species. Forensic science utilizes physical anthropology expertise in identifying human and animal remains, assisting in determining the cause of death, and for expert testimony in trials.

## 24.2 | Animal Primary Tissues

In this section, you will explore the following questions:

- What are characteristics of epithelial tissues?
- What are the different types of connective tissues in animals?
- What are differences among the three types of muscle tissue?
- What are characteristics of nervous tissue?

### Connection for AP® Courses

The content described in this section is not within the scope of AP®. However, we have already learned that the relationship between structure and function includes the cellular level, and we will continue to reinforce that when we explore the nervous system later.

The tissues of multicellular, complex animals are four primary types: epithelial, connective, muscle, and nervous. Recall that tissues are groups of similar cells group of similar cells carrying out related functions. These tissues combine to form organs—like the skin or kidney—that have specific, specialized functions within the body. Organs are organized into organ systems to perform functions; examples include the circulatory system, which consists of the heart and blood vessels, and the digestive system, consisting of several organs, including the stomach, intestines, liver, and pancreas. Organ systems come together to create an entire organism.

### Epithelial Tissues

**Epithelial tissues** cover the outside of organs and structures in the body and line the lumens of organs in a single layer or multiple layers of cells. The types of epithelia are classified by the shapes of cells present and the number of layers of cells. Epithelia composed of a single layer of cells is called **simple epithelia**; epithelial tissue composed of multiple layers is called **stratified epithelia**. **Table 24.2** summarizes the different types of epithelial tissues.

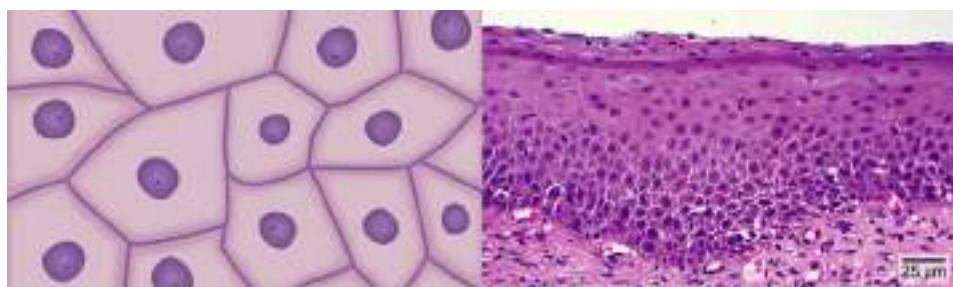

Different Types of Epithelial Tissues

| Cell shape   | Description                                             | Location                                                             |
|--------------|---------------------------------------------------------|----------------------------------------------------------------------|
| squamous     | flat, irregular round shape                             | simple: lung alveoli, capillaries<br>stratified: skin, mouth, vagina |
| cuboidal     | cube shaped, central nucleus                            | glands, renal tubules                                                |
| columnar     | tall, narrow, nucleus toward base<br>nucleus along cell | simple: digestive tract<br>pseudostratified: respiratory tract       |
| transitional | round, simple but appear stratified                     | urinary bladder                                                      |

Table 24.2

#### Squamous Epithelia

**Squamous epithelial** cells are generally round, flat, and have a small, centrally located nucleus. The cell outline is slightly irregular, and cells fit together to form a covering or lining. When the cells are arranged in a single layer (simple epithelia), they facilitate diffusion in tissues, such as the areas of gas exchange in the lungs and the exchange of nutrients and waste at blood capillaries.

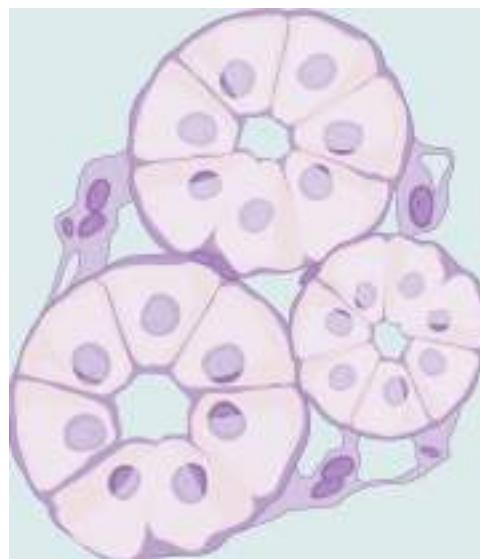

**Figure 24.7** Squamous epithelia cells (a) have a slightly irregular shape, and a small, centrally located nucleus. These cells can be stratified into layers, as in (b) this human cervix specimen. (credit b: modification of work by Ed Uthman; scale-bar data from Matt Russell)

**Figure 24.7a** illustrates a layer of squamous cells with their membranes joined together to form an epithelium. Image **Figure 24.7b** illustrates squamous epithelial cells arranged in stratified layers, where protection is needed on the body from outside abrasion and damage. This is called a stratified squamous epithelium and occurs in the skin and in tissues lining the mouth and vagina.

#### Cuboidal Epithelia

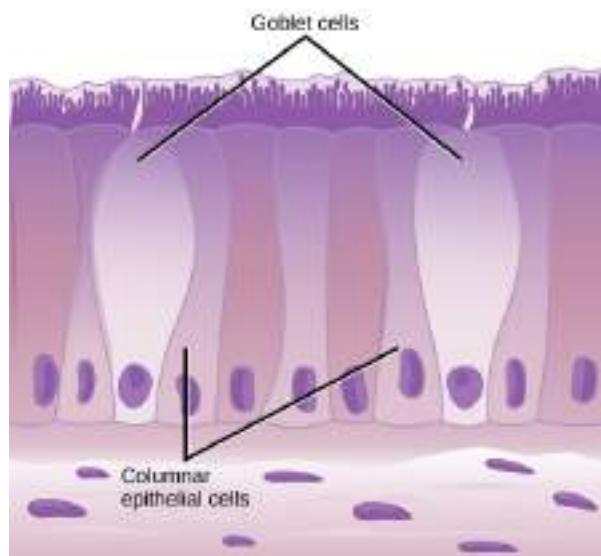

**Cuboidal epithelial** cells, shown in **Figure 24.8**, are cube-shaped with a single, central nucleus. They are most commonly found in a single layer representing a simple epithelia in glandular tissues throughout the body where they prepare and secrete glandular material. They are also found in the walls of tubules and in the ducts of the kidney and liver.

**Figure 24.8** Simple cuboidal epithelial cells line tubules in the mammalian kidney, where they are involved in filtering the blood.

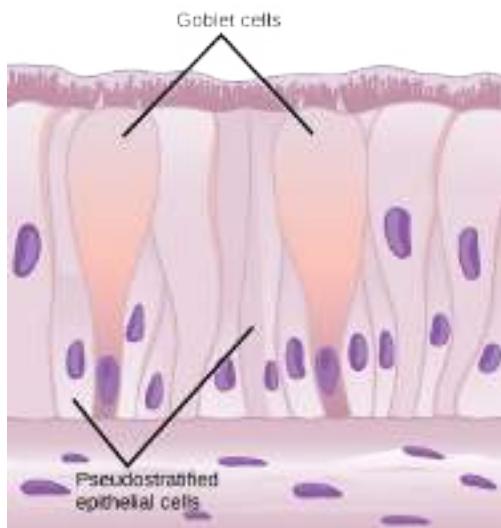

#### Columnar Epithelia

**Columnar epithelial** cells are taller than they are wide: they resemble a stack of columns in an epithelial layer, and are most commonly found in a single-layer arrangement. The nuclei of columnar epithelial cells in the digestive tract appear to be lined up at the base of the cells, as illustrated in **Figure 24.9**. These cells absorb material from the lumen of the digestive tract and prepare it for entry into the body through the circulatory and lymphatic systems.

**Figure 24.9** Simple columnar epithelial cells absorb material from the digestive tract. Goblet cells secret mucous into the digestive tract lumen.

Columnar epithelial cells lining the respiratory tract appear to be stratified. However, each cell is attached to the base membrane of the tissue and, therefore, they are simple tissues. The nuclei are arranged at different levels in the layer of cells, making it appear as though there is more than one layer, as seen in **Figure 24.10**. This is called **pseudostratified**, columnar epithelia. This cellular covering has cilia at the apical, or free, surface of the cells. The cilia enhance the movement of mucous and trapped particles out of the respiratory tract, helping to protect the system from invasive microorganisms and harmful material that has been breathed into the body. Goblet cells are interspersed in some tissues (such as the lining of the trachea). The goblet cells contain mucous that traps irritants, which in the case of the trachea keep these irritants from getting into the lungs.

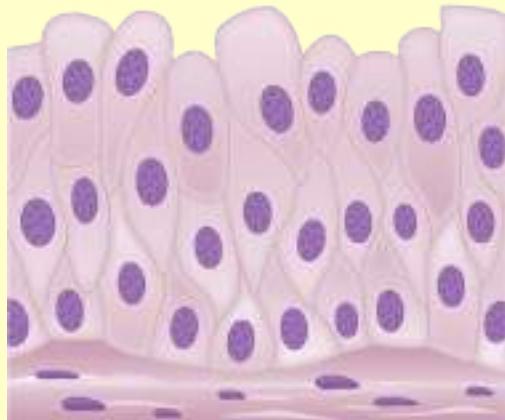

**Figure 24.10** Pseudostratified columnar epithelia line the respiratory tract. They exist in one layer, but the arrangement of nuclei at different levels makes it appear that there is more than one layer. Goblet cells interspersed between the columnar epithelial cells secrete mucous into the respiratory tract.

### Transitional Epithelia

**Transitional** or uroepithelial cells appear only in the urinary system, primarily in the bladder and ureter. These cells are arranged in a stratified layer, but they have the capability of appearing to pile up on top of each other in a relaxed, empty bladder, as illustrated in **Figure 24.11**. As the urinary bladder fills, the epithelial layer unfolds and expands to hold the volume of urine introduced into it. As the bladder fills, it expands and the lining becomes thinner. In other words, the tissue transitions from thick to thin.

## visual CONNECTION

**Figure 24.11** Transitional epithelia of the urinary bladder undergo changes in thickness depending on how full the bladder is.

An empty bladder is composed of piled up transitional cells with a folded epithelial lining. What would you predict happens to those cells as the bladder fills with urine?

- a. The epithelial lining unfolds and becomes thicker.
- b. The epithelial lining remains folded with the cells piled up.
- c. The epithelial lining unfolds and becomes thinner.
- d. The epithelial lining unfolds, but remains the same thickness.

## Connective Tissues

**Connective tissues** are made up of a matrix consisting of living cells and a non-living substance, called the ground substance. The ground substance is made of an organic substance (usually a protein) and an inorganic substance (usually a mineral or water). The principal cell of connective tissues is the fibroblast. This cell makes the fibers found in nearly all of the connective tissues. Fibroblasts are motile, able to carry out mitosis, and can synthesize whichever connective tissue is needed. Macrophages, lymphocytes, and, occasionally, leukocytes can be found in some of the tissues. Some tissues have specialized cells that are not found in the others. The **matrix** in connective tissues gives the tissue its density. When a connective tissue has a high concentration of cells or fibers, it has proportionally a less dense matrix.

The organic portion or protein fibers found in connective tissues are either collagen, elastic, or reticular fibers. Collagen fibers provide strength to the tissue, preventing it from being torn or separated from the surrounding tissues. Elastic fibers are made of the protein elastin; this fiber can stretch to one and one half of its length and return to its original size and shape. Elastic fibers provide flexibility to the tissues. Reticular fibers are the third type of protein fiber found in connective tissues. This fiber consists of thin strands of collagen that form a network of fibers to support the tissue and other organs to which it is connected. The various types of connective tissues, the types of cells and fibers they are made of, and sample locations of the tissues is summarized in **Table 24.3**.

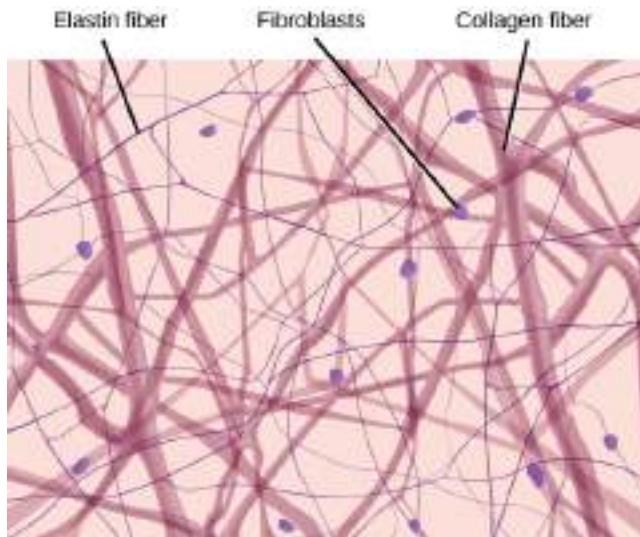

## Connective Tissues

| Tissue                           | Cells                                                        | Fibers                                                            | Location                                                      |
|----------------------------------|--------------------------------------------------------------|-------------------------------------------------------------------|---------------------------------------------------------------|
| loose/areolar                    | fibroblasts, macrophages, some lymphocytes, some neutrophils | few: collagen, elastic, reticular                                 | around blood vessels; anchors epithelia                       |
| dense, fibrous connective tissue | fibroblasts, macrophages,                                    | mostly collagen                                                   | irregular: skin regular: tendons, ligaments                   |
| cartilage                        | chondrocytes, chondroblasts                                  | hyaline: few collagen<br>fibrocartilage: large amount of collagen | shark skeleton, fetal bones, human ears, intervertebral discs |
| bone                             | osteoblasts, osteocytes, osteoclasts                         | some: collagen, elastic                                           | vertebrate skeletons                                          |
| adipose                          | adipocytes                                                   | few                                                               | adipose (fat)                                                 |
| blood                            | red blood cells, white blood cells                           | none                                                              | blood                                                         |

**Table 24.3**

### Loose/Areolar Connective Tissue

**Loose connective tissue**, also called areolar connective tissue, has a sampling of all of the components of a connective tissue. As illustrated in **Figure 24.12**, loose connective tissue has some fibroblasts; macrophages are present as well. Collagen fibers are relatively wide and stain a light pink, while elastic fibers are thin and stain dark blue to black. The space between the formed elements of the tissue is filled with the matrix. The material in the connective tissue gives it a loose consistency similar to a cotton ball that has been pulled apart. Loose connective tissue is found around every blood vessel and helps to keep the vessel in place. The tissue is also found around and between most body organs. In summary, areolar tissue is tough, yet flexible, and comprises membranes.

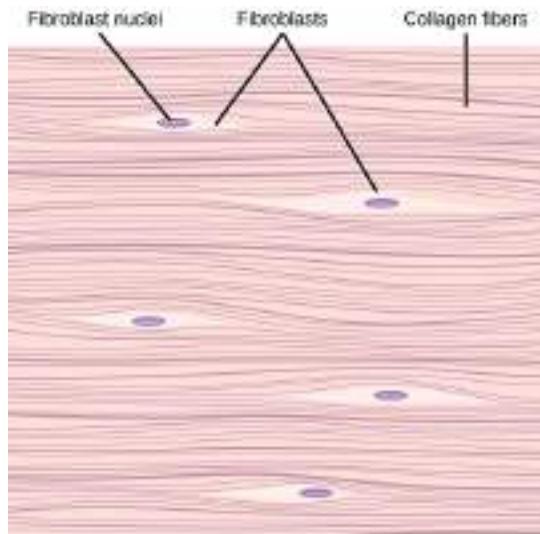

**Figure 24.12** Loose connective tissue is composed of loosely woven collagen and elastic fibers. The fibers and other components of the connective tissue matrix are secreted by fibroblasts.

### Fibrous Connective Tissue

**Fibrous connective tissues** contain large amounts of collagen fibers and few cells or matrix material. The fibers can be arranged irregularly or regularly with the strands lined up in parallel. Irregularly arranged fibrous connective tissues are found in areas of the body where stress occurs from all directions, such as the dermis of the skin. Regular fibrous connective tissue, shown in **Figure 24.13**, is found in tendons (which connect muscles to bones) and ligaments (which connect bones

to bones).

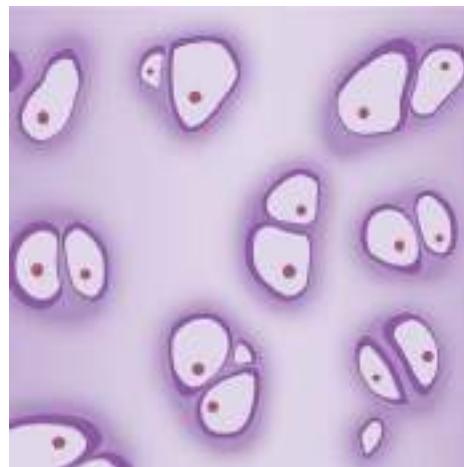

**Figure 24.13** Fibrous connective tissue from the tendon has strands of collagen fibers lined up in parallel.

### Cartilage

**Cartilage** is a connective tissue with a large amount of the matrix and variable amounts of fibers. The cells, called **chondrocytes**, make the matrix and fibers of the tissue. Chondrocytes are found in spaces within the tissue called **lacunae**.

A cartilage with few collagen and elastic fibers is hyaline cartilage, illustrated in **Figure 24.14**. The lacunae are randomly scattered throughout the tissue and the matrix takes on a milky or scrubbed appearance with routine histological stains. Sharks have cartilaginous skeletons, as does nearly the entire human skeleton during a specific pre-birth developmental stage. A remnant of this cartilage persists in the outer portion of the human nose. Hyaline cartilage is also found at the ends of long bones, reducing friction and cushioning the articulations of these bones.

**Figure 24.14** Hyaline cartilage consists of a matrix with cells called chondrocytes embedded in it. The chondrocytes exist in cavities in the matrix called lacunae.

Elastic cartilage has a large amount of elastic fibers, giving it tremendous flexibility. The ears of most vertebrate animals contain this cartilage as do portions of the larynx, or voice box. Fibrocartilage contains a large amount of collagen fibers, giving the tissue tremendous strength. Fibrocartilage comprises the intervertebral discs in vertebrate animals. Hyaline cartilage found in movable joints such as the knee and shoulder becomes damaged as a result of age or trauma. Damaged hyaline cartilage is replaced by fibrocartilage and results in the joints becoming “stiff.”

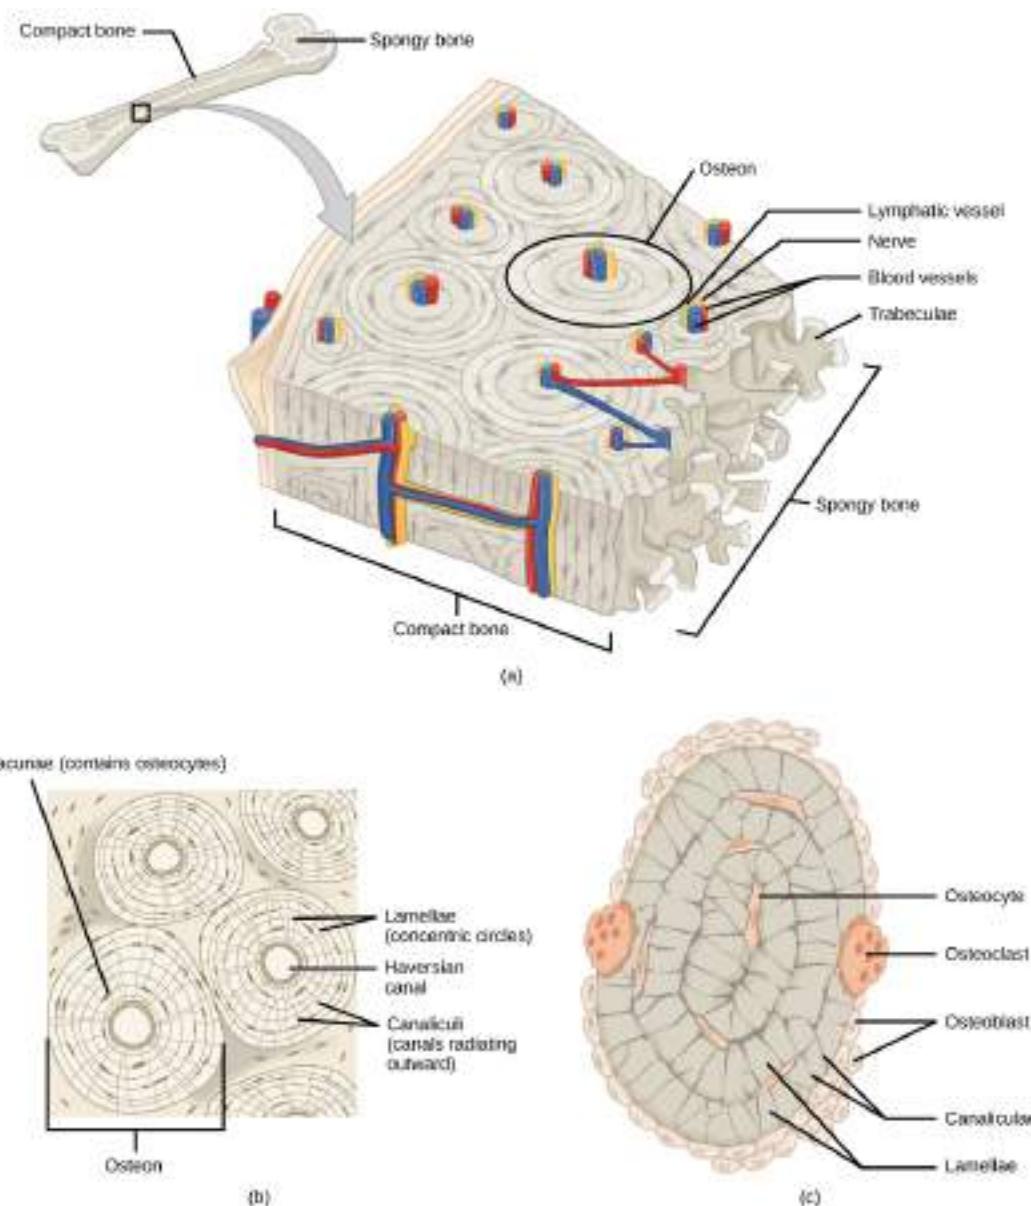

### Bone

Bone, or osseous tissue, is a connective tissue that has a large amount of two different types of matrix material. The organic matrix is similar to the matrix material found in other connective tissues, including some amount of collagen and elastic fibers. This gives strength and flexibility to the tissue. The inorganic matrix consists of mineral salts—mostly calcium

salts—that give the tissue hardness. Without adequate organic material in the matrix, the tissue breaks; without adequate inorganic material in the matrix, the tissue bends.

There are three types of cells in bone: osteoblasts, osteocytes, and osteoclasts. Osteoblasts are active in making bone for growth and remodeling. Osteoblasts deposit bone material into the matrix and, after the matrix surrounds them, they continue to live, but in a reduced metabolic state as osteocytes. Osteocytes are found in lacunae of the bone. Osteoclasts are active in breaking down bone for bone remodeling, and they provide access to calcium stored in tissues. Osteoclasts are usually found on the surface of the tissue.

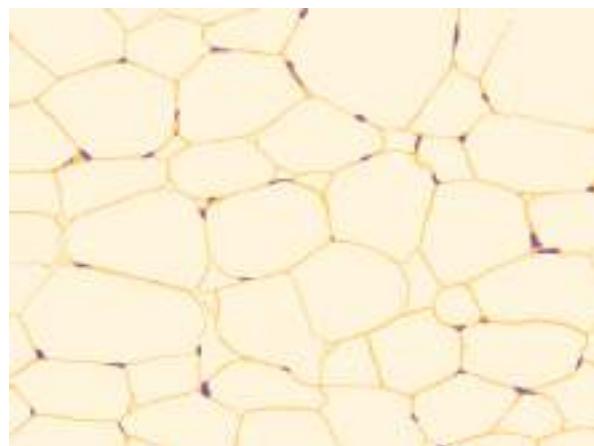

Bone can be divided into two types: compact and spongy. Compact bone is found in the shaft (or diaphysis) of a long bone and the surface of the flat bones, while spongy bone is found in the end (or epiphysis) of a long bone. Compact bone is organized into subunits called **osteons**, as illustrated in **Figure 24.15**. A blood vessel and a nerve are found in the center of the structure within the Haversian canal, with radiating circles of lacunae around it known as lamellae. The wavy lines seen between the lacunae are microchannels called **canaliculari**; they connect the lacunae to aid diffusion between the cells. Spongy bone is made of tiny plates called **trabeculae**; these plates serve as struts to give the spongy bone strength. Over time, these plates can break causing the bone to become less resilient. Bone tissue forms the internal skeleton of vertebrate animals, providing structure to the animal and points of attachment for tendons.

**Figure 24.15** (a) Compact bone is a dense matrix on the outer surface of bone. Spongy bone, inside the compact bone, is porous with web-like trabeculae. (b) Compact bone is organized into rings called osteons. Blood vessels, nerves, and lymphatic vessels are found in the central Haversian canal. Rings of lamellae surround the Haversian canal. Between the lamellae are cavities called lacunae. Canaliculi are microchannels connecting the lacunae together. (c) Osteoblasts surround the exterior of the bone. Osteoclasts bore tunnels into the bone and osteocytes are found in the lacunae.

#### Adipose Tissue

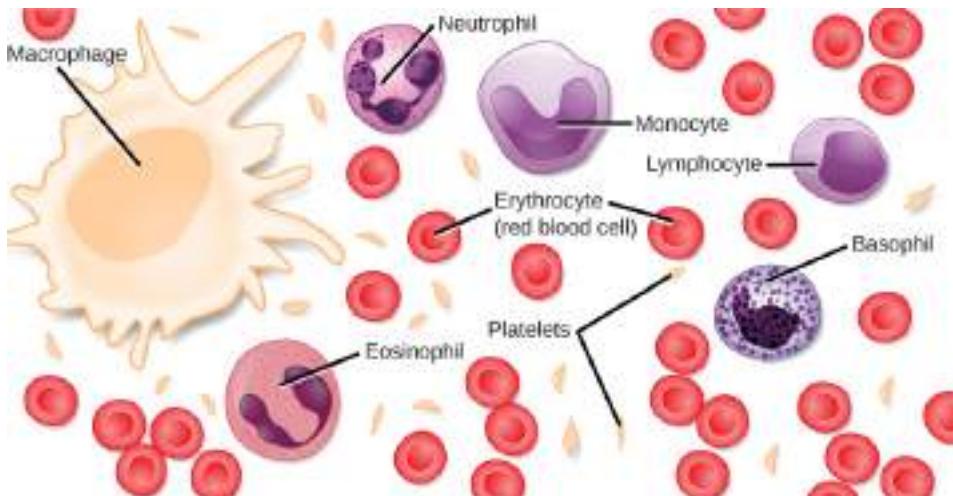

Adipose tissue, or fat tissue, is considered a connective tissue even though it does not have fibroblasts or a real matrix and only has a few fibers. Adipose tissue is made up of cells called adipocytes that collect and store fat in the form of triglycerides, for energy metabolism. Adipose tissues additionally serve as insulation to help maintain body temperatures, allowing animals to be endothermic, and they function as cushioning against damage to body organs. Under a microscope, adipose tissue cells appear empty due to the extraction of fat during the processing of the material for viewing, as seen in **Figure 24.16**. The thin lines in the image are the cell membranes, and the nuclei are the small, black dots at the edges of the cells.

**Figure 24.16** Adipose is a connective tissue made up of cells called adipocytes. Adipocytes have small nuclei localized at the cell edge.

### Blood

Blood is considered a connective tissue because it has a matrix, as shown in **Figure 24.17**. The living cell types are red blood cells (RBC), also called erythrocytes, and white blood cells (WBC), also called leukocytes. The fluid portion of whole blood, its matrix, is commonly called plasma.

**Figure 24.17** Blood is a connective tissue that has a fluid matrix, called plasma, and no fibers. Erythrocytes (red blood cells), the predominant cell type, are involved in the transport of oxygen and carbon dioxide. Also present are various leukocytes (white blood cells) involved in immune response.

The cell found in greatest abundance in blood is the erythrocyte. Erythrocytes are counted in millions in a blood sample: the average number of red blood cells in primates is 4.7 to 5.5 million cells per microliter. Erythrocytes are consistently the same size in a species, but vary in size between species. For example, the average diameter of a primate red blood cell is 7.5  $\mu\text{m}$ , a dog is close at 7.0  $\mu\text{m}$ , but a cat's RBC diameter is 5.9  $\mu\text{m}$ . Sheep erythrocytes are even smaller at 4.6  $\mu\text{m}$ . Mammalian erythrocytes lose their nuclei and mitochondria when they are released from the bone marrow where they are made. Fish, amphibian, and avian red blood cells maintain their nuclei and mitochondria throughout the cell's life. The principal job of an erythrocyte is to carry and deliver oxygen to the tissues.

Leukocytes are the predominant white blood cells found in the peripheral blood. Leukocytes are counted in the thousands in the blood with measurements expressed as ranges: primate counts range from 4,800 to 10,800 cells per  $\mu\text{l}$ , dogs from 5,600 to 19,200 cells per  $\mu\text{l}$ , cats from 8,000 to 25,000 cells per  $\mu\text{l}$ , cattle from 4,000 to 12,000 cells per  $\mu\text{l}$ , and pigs from 11,000 to 22,000 cells per  $\mu\text{l}$ .

Lymphocytes function primarily in the immune response to foreign antigens or material. Different types of lymphocytes make antibodies tailored to the foreign antigens and control the production of those antibodies. Neutrophils are phagocytic cells and they participate in one of the early lines of defense against microbial invaders, aiding in the removal of bacteria that has entered the body. Another leukocyte that is found in the peripheral blood is the monocyte. Monocytes give rise to

phagocytic macrophages that clean up dead and damaged cells in the body, whether they are foreign or from the host animal. Two additional leukocytes in the blood are eosinophils and basophils—both help to facilitate the inflammatory response.

The slightly granular material among the cells is a cytoplasmic fragment of a cell in the bone marrow. This is called a platelet or thrombocyte. Platelets participate in the stages leading up to coagulation of the blood to stop bleeding through damaged blood vessels. Blood has a number of functions, but primarily it transports material through the body to bring nutrients to cells and remove waste material from them.

## Muscle Tissues

There are three types of muscle in animal bodies: smooth, skeletal, and cardiac. They differ by the presence or absence of striations or bands, the number and location of nuclei, whether they are voluntarily or involuntarily controlled, and their location within the body. **Table 24.4** summarizes these differences.

### Types of Muscles

| Type of Muscle | Striations | Nuclei             | Control     | Location         |
|----------------|------------|--------------------|-------------|------------------|
| smooth         | no         | single, in center  | involuntary | visceral organs  |
| skeletal       | yes        | many, at periphery | voluntary   | skeletal muscles |
| cardiac        | yes        | single, in center  | involuntary | heart            |

**Table 24.4**

### Smooth Muscle

Smooth muscle does not have striations in its cells. It has a single, centrally located nucleus, as shown in **Figure 24.18**. Constriction of smooth muscle occurs under involuntary, autonomic nervous control and in response to local conditions in the tissues. Smooth muscle tissue is also called non-striated as it lacks the banded appearance of skeletal and cardiac muscle. The walls of blood vessels, the tubes of the digestive system, and the tubes of the reproductive systems are composed of mostly smooth muscle.

**Figure 24.18** Smooth muscle cells do not have striations, while skeletal muscle cells do. Cardiac muscle cells have striations, but, unlike the multinucleate skeletal cells, they have only one nucleus. Cardiac muscle tissue also has intercalated discs, specialized regions running along the plasma membrane that join adjacent cardiac muscle cells and assist in passing an electrical impulse from cell to cell.

### Skeletal Muscle

Skeletal muscle has striations across its cells caused by the arrangement of the contractile proteins actin and myosin. These muscle cells are relatively long and have multiple nuclei along the edge of the cell. Skeletal muscle is under voluntary, somatic nervous system control and is found in the muscles that move bones. **Figure 24.18** illustrates the histology of skeletal muscle.

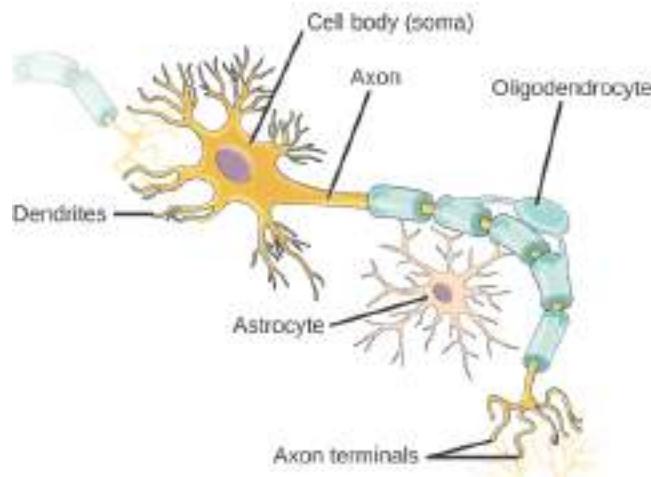

### Cardiac Muscle

Cardiac muscle, shown in **Figure 24.18**, is found only in the heart. Like skeletal muscle, it has cross striations in its cells, but cardiac muscle has a single, centrally located nucleus. Cardiac muscle is not under voluntary control but can be influenced by the autonomic nervous system to speed up or slow down. An added feature to cardiac muscle cells is a line that extends along the end of the cell as it abuts the next cardiac cell in the row. This line is called an intercalated disc: it assists in passing electrical impulse efficiently from one cell to the next and maintains the strong connection between neighboring cardiac cells.

## Nervous Tissues

Nervous tissues are made of cells specialized to receive and transmit electrical impulses from specific areas of the body and to send them to specific locations in the body. The main cell of the nervous system is the neuron, illustrated in **Figure**

**24.19.** The large structure with a central nucleus is the cell body of the neuron. Projections from the cell body are either dendrites specialized in receiving input or a single axon specialized in transmitting impulses. Some glial cells are also shown. Astrocytes regulate the chemical environment of the nerve cell, and oligodendrocytes insulate the axon so the electrical nerve impulse is transferred more efficiently. Other glial cells that are not shown support the nutritional and waste requirements of the neuron. Some of the glial cells are phagocytic and remove debris or damaged cells from the tissue. A nervous tissue consists of neurons and glial cells.

**Figure 24.19** The neuron has projections called dendrites that receive signals and projections called axons that send signals. Also shown are two types of glial cells: astrocytes regulate the chemical environment of the nerve cell, and oligodendrocytes insulate the axon so the electrical nerve impulse is transferred more efficiently.

Click through the **interactive review** (<http://openstaxcollege.org/l/tissues>) to learn more about epithelial tissues.

Why would a single layer of flat epithelial cells rather than cuboidal cells (cube-shaped) cells function more efficiently in diffusion?

- As a single layer of flat epithelia are more tightly knit than cuboidal cells.
- As diffusion of nutrients and gas is easier across a single layer of flat epithelial cells than cuboidal cells.
- As diffusion of only gases is easier across a single layer of flat epithelial cells than cuboidal cells.
- As active transport of nutrients and gas is easier across a single layer of flat epithelial cells than cuboidal cells.

## career CONNECTION

### Pathologist

A pathologist is a medical doctor or veterinarian who has specialized in the laboratory detection of disease in animals, including humans. These professionals complete medical school education and follow it with an extensive post-graduate residency at a medical center. A pathologist may oversee clinical laboratories for the evaluation of body tissue and blood samples for the detection of disease or infection. They examine tissue specimens through a microscope to identify diseases. Some pathologists perform autopsies to determine the cause of death and the progression of disease.

## 24.3 | Homeostasis

In this section, you will explore the following questions:

- What is homeostasis?
- What factors affect homeostasis?
- What are differences between negative and positive feedback mechanisms used in homeostasis?
- What are differences between thermoregulation mechanisms in endothermic and ectothermic animals?

### Connection for AP<sup>®</sup> Courses

Animals must be able to maintain homeostasis—the ability to maintain dynamic equilibrium around a set point—while also being able to respond to changing conditions. For example, as an endotherm, your body temperature remains fairly constant around 37°C or 98.6°F. If your temperature climbs above the set point, you sweat to cool off; if your temperature drops below the set point, you shiver to warm up. Your blood glucose levels also remain fairly constant because the liver removes glucose from the blood and converts it to glycogen; when the body cells require glucose, glycogen is broken down. (You can probably hypothesize how your liver will respond if you eat a dozen jelly donuts!) The failure to maintain homeostasis can be detrimental and can even cause death. Consequently, **negative and/or positive feedback loops** regulate homeostasis.

Negative feedback mechanisms result in slight fluctuations above and below the set point. For example, if you were to consume a dozen jelly donuts, your blood sugar level would rise, and your pancreas would release insulin, a hormone involved in the conversion of glucose to glycogen, thus returning your blood glucose level to its appropriate set point. By comparison, **positive feedback** amplifies responses in the same direction, with the variable initiating the response moving the system even further away from the set point. There are fewer examples of positive feedback, but one is the onset of labor in childbirth when uterine contractions increase in strength with the secretion of oxytocin, another hormone. However, the loss of internal equilibrium due to positive feedback can be detrimental; for example, a small area of damaged heart tissue can precipitate a heart attack which, in turn, damages even more cardiac muscle.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP Biology<sup>®</sup> Curriculum Framework. The AP<sup>®</sup> Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP<sup>®</sup> Biology course, an inquiry-based laboratory experience, instructional activities, and AP<sup>®</sup> exam questions. A learning objective merges required content with one or more of the seven Science Practices.

| <b>Learning Objective</b>  | <b>2.18</b> The student is able to make predictions about how organisms use negative feedback mechanisms to maintain their internal environments.                                 |
| <b>Essential Knowledge</b> | <b>2.C.1</b> Organisms use feedback mechanisms to maintain their internal environments and respond to external environmental changes.                                             |
| <b>Science Practice</b>    | <b>6.4</b> The student can make claims and predictions about natural phenomena based on scientific theories and models.                                                           |
| <b>Learning Objective</b>  | <b>2.19</b> The student is able to make predictions about how positive feedback mechanisms amplify activities and processes in organisms based on scientific theories and models. |
| <b>Essential Knowledge</b> | <b>2.C.1</b> Organisms use feedback mechanisms to maintain their internal environments and respond to external environmental changes.                                             |
| <b>Science Practice</b>    | <b>6.1</b> The student can justify claims with evidence.                                                                                                                          |
| <b>Learning Objective</b>  | <b>2.20</b> The student is able to justify that positive feedback mechanisms amplify responses in organisms.                                                                      |

Animal organs and organ systems constantly adjust to internal and external changes through a process called homeostasis (“steady state”). These changes might be in the level of glucose or calcium in blood or in external temperatures. Homeostasis means to maintain dynamic equilibrium in the body. It is dynamic because it is constantly adjusting to the changes that the body’s systems encounter. It is equilibrium because body functions are kept within specific ranges. Even an animal that is apparently inactive is maintaining this homeostatic equilibrium.

## Homeostatic Process

The goal of homeostasis is the maintenance of equilibrium around a point or value called a set point. While there are normal fluctuations from the set point, the body’s systems will usually attempt to go back to this point. A change in the internal or external environment is called a stimulus and is detected by a receptor; the response of the system is to adjust the deviation parameter toward the set point. For instance, if the body becomes too warm, adjustments are made to cool the animal. If the blood’s glucose rises after a meal, adjustments are made to lower the blood glucose level by getting the nutrient into tissues that need it or to store it for later use.

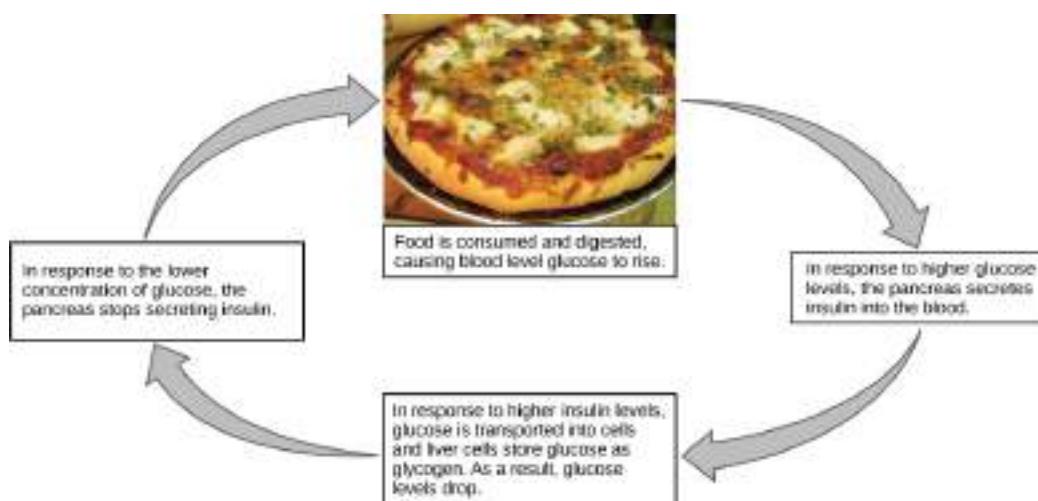

## Control of Homeostasis

When a change occurs in an animal’s environment, an adjustment must be made. The receptor senses the change in the environment, then sends a signal to the control center (in most cases, the brain) which in turn generates a response that is signaled to an effector. The effector is a muscle (that contracts or relaxes) or a gland that secretes. Homeostasis is

maintained by negative feedback loops. Positive feedback loops actually push the organism further out of homeostasis, but may be necessary for life to occur. Homeostasis is controlled by the nervous and endocrine system of mammals.

### Negative Feedback Mechanisms

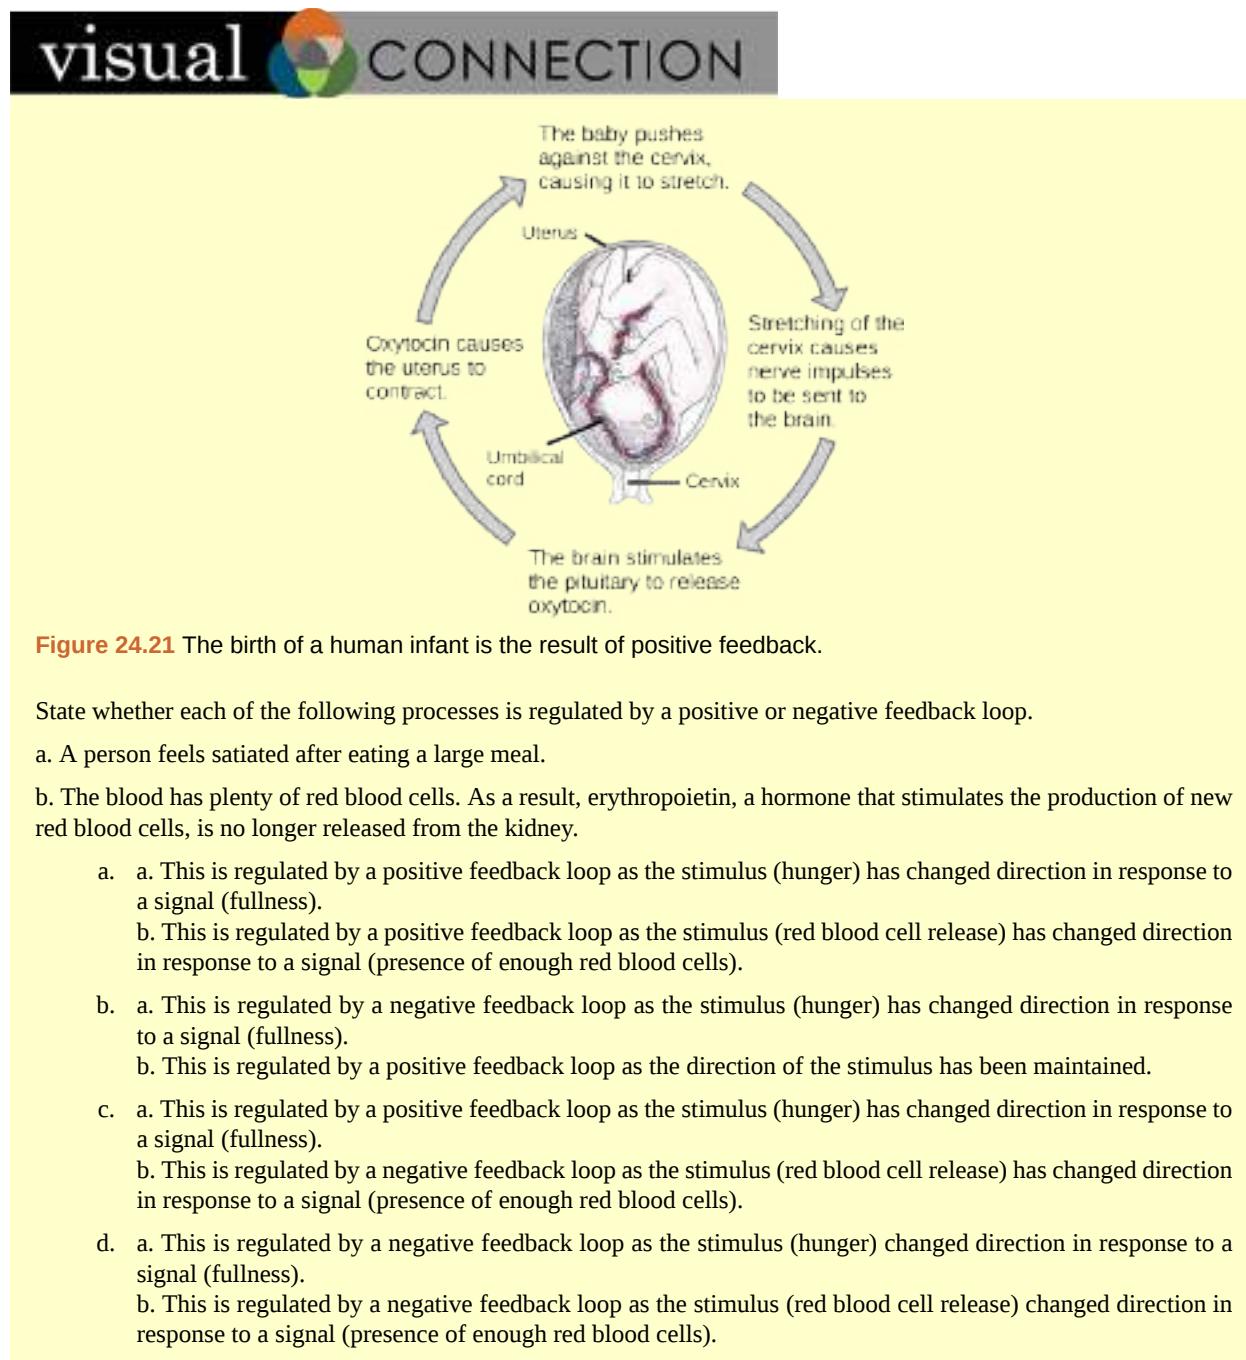

Any homeostatic process that changes the direction of the stimulus is a negative feedback loop. It may either increase or decrease the stimulus, but the stimulus is not allowed to continue as it did before the receptor sensed it. In other words, if a level is too high, the body does something to bring it down, and conversely, if a level is too low, the body does something to make it go up. Hence the term negative feedback. An example is animal maintenance of blood glucose levels. When an animal has eaten, blood glucose levels rise. This is sensed by the nervous system. Specialized cells in the pancreas sense this, and the hormone insulin is released by the endocrine system. Insulin causes blood glucose levels to decrease, as would be expected in a negative feedback system, as illustrated in **Figure 24.20**. However, if an animal has not eaten and blood glucose levels decrease, this is sensed in another group of cells in the pancreas, and the hormone glucagon is released causing glucose levels to increase. This is still a negative feedback loop, but not in the direction expected by the use of the term “negative.” Another example of an increase as a result of the feedback loop is the control of blood calcium. If calcium levels decrease, specialized cells in the parathyroid gland sense this and release parathyroid hormone (PTH), causing an increased absorption of calcium through the intestines and kidneys and, possibly, the breakdown of bone in order to liberate calcium. The effects of PTH are to raise blood levels of the element. Negative feedback loops are the predominant mechanism used in homeostasis.

**Figure 24.20** Blood sugar levels are controlled by a negative feedback loop. (credit: modification of work by Jon Sullivan)

### Positive Feedback Loop

A positive feedback loop maintains the direction of the stimulus, possibly accelerating it. Few examples of positive feedback loops exist in animal bodies, but one is found in the cascade of chemical reactions that result in blood clotting, or coagulation. As one clotting factor is activated, it activates the next factor in sequence until a fibrin clot is achieved. The direction is maintained, not changed, so this is positive feedback. Another example of positive feedback is uterine contractions during childbirth, as illustrated in **Figure 24.21**. The hormone oxytocin, made by the endocrine system, stimulates the contraction of the uterus. This produces pain sensed by the nervous system. Instead of lowering the oxytocin and causing the pain to subside, more oxytocin is produced until the contractions are powerful enough to produce childbirth.

### Set Point

It is possible to adjust a system's set point. When this happens, the feedback loop works to maintain the new setting. An example of this is blood pressure: over time, the normal or set point for blood pressure can increase as a result of continued increases in blood pressure. The body no longer recognizes the elevation as abnormal and no attempt is made to return to the lower set point. The result is the maintenance of an elevated blood pressure that can have harmful effects on the body. Medication can lower blood pressure and lower the set point in the system to a more healthy level. This is called a process of **alteration** of the set point in a feedback loop.

Changes can be made in a group of body organ systems in order to maintain a set point in another system. This is called **acclimatization**. This occurs, for instance, when an animal migrates to a higher altitude than it is accustomed to. In order to adjust to the lower oxygen levels at the new altitude, the body increases the number of red blood cells circulating in the

blood to ensure adequate oxygen delivery to the tissues. Another example of acclimatization is animals that have seasonal changes in their coats: a heavier coat in the winter ensures adequate heat retention, and a light coat in summer assists in keeping body temperature from rising to harmful levels.

Feedback mechanisms can be understood in terms of driving a race car along a track: watch a short **video lesson** ([http://openstaxcollege.org/l/feedback\\_loops](http://openstaxcollege.org/l/feedback_loops)) on positive and negative feedback loops.

Voltage-gated sodium channels occur in the cell membranes of nerve cells. They open in response to sodium entering the cell, which in turn, allows more sodium to enter the cell. Is this a positive or negative feedback loop and why?

- This is a positive feedback loop as voltage-gated sodium channels open in response to sodium influx and then close when enough sodium has entered through the channels.
- This is a negative feedback loop as voltage-gated sodium channels open in response to sodium influx and then close when enough sodium has entered through the channels.
- This is a positive feedback loop as voltage-gated sodium channels open in response to sodium influx, which allows more sodium to go in through the channels.
- This is a negative feedback loop as voltage-gated sodium channels open in response to sodium influx, which allows more sodium to go in through the channels.

### Think About It

How are negative feedback loops used to regulate body homeostasis? How is a condition such as diabetes a good example of the failure of a set point in humans? Hypothesize and draw a diagram that shows what you think is the feedback failure for a person with diabetes.

## Homeostasis: Thermoregulation

Body temperature affects body activities. Generally, as body temperature rises, enzyme activity rises as well. For every ten degree centigrade rise in temperature, enzyme activity doubles, up to a point. Body proteins, including enzymes, begin to denature and lose their function with high heat (around 50°C for mammals). Enzyme activity will decrease by half for every ten degree centigrade drop in temperature, to the point of freezing, with a few exceptions. Some fish can withstand freezing solid and return to normal with thawing.

Watch this **Discovery Channel video** (<http://openstaxcollege.org/l/thermoregulate>) on thermoregulation to see illustrations of this process in a variety of animals.

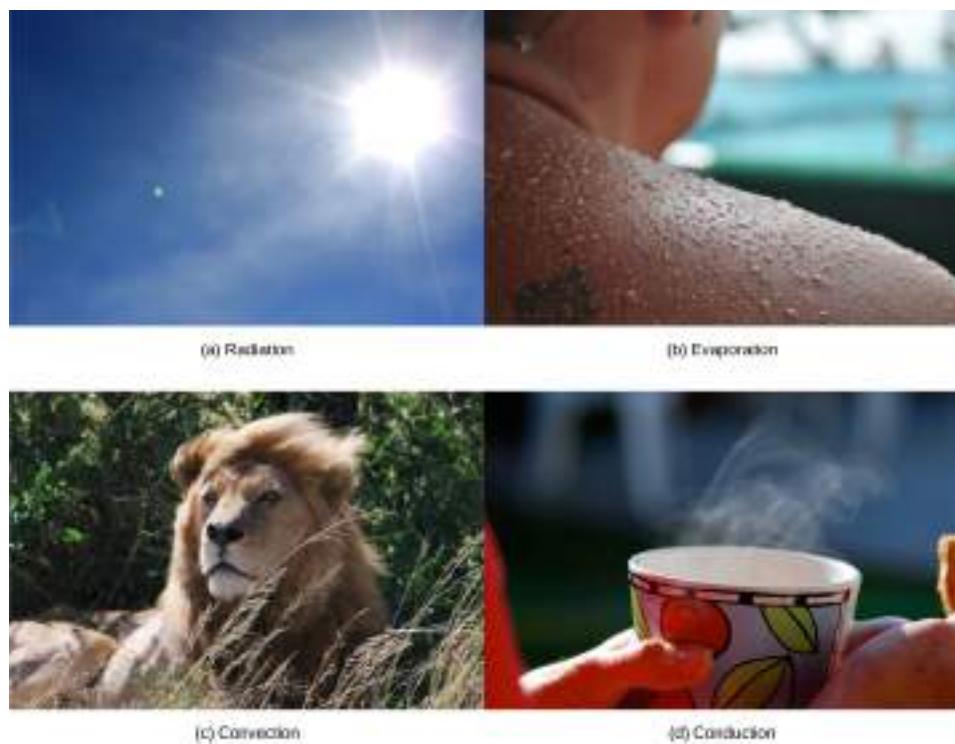

How does the loose skin of an elephant help it regulate body temperature?

- a. Loose skin is thicker, which allows the excess heat to dissipate quickly through the skin.
- b. Loose skin brings more heat and blood to the body surface, facilitating heat loss.
- c. Loose skin contains greater skin area, which allows excess heat to dissipate as heat loss occurs through the skin.
- d. Loose skin has smaller skin area, which allows excess heat to dissipate as heat loss occurs through the skin.

## Endotherms and Ectotherms

Animals can be divided into two groups: some maintain a constant body temperature in the face of differing environmental temperatures, while others have a body temperature that is the same as their environment and thus varies with the environment. Animals that do not control their body temperature are ectotherms. This group has been called cold-blooded, but the term may not apply to an animal in the desert with a very warm body temperature. In contrast to ectotherms, which rely on external temperatures to set their body temperatures, poikilotherms are animals with constantly varying internal temperatures. An animal that maintains a constant body temperature in the face of environmental changes is called a homeotherm. Endotherms are animals that rely on internal sources for body temperature but which can exhibit extremes in temperature. These animals are able to maintain a level of activity at cooler temperature, which an ectotherm cannot due to differing enzyme levels of activity.

Heat can be exchanged between an animal and its environment through four mechanisms: radiation, evaporation, convection, and conduction (Figure 24.22). Radiation is the emission of electromagnetic “heat” waves. Heat comes from the sun in this manner and radiates from dry skin the same way. Heat can be removed with liquid from a surface during evaporation. This occurs when a mammal sweats. Convection currents of air remove heat from the surface of dry skin as the air passes over it. Heat will be conducted from one surface to another during direct contact with the surfaces, such as an animal resting on a warm rock.

**Figure 24.22** Heat can be exchanged by four mechanisms: (a) radiation, (b) evaporation, (c) convection, or (d) conduction. (credit b: modification of work by "Kullez"/Flickr; credit c: modification of work by Chad Rosenthal; credit d: modification of work by "stacey.d"/Flickr)

## everyday CONNECTION for AP<sup>®</sup> Courses

**Figure 24.23** The body temperature of ectotherms varies with the environment. For that reason, reptiles, such as this American alligator, bask in the sun to warm themselves.

If an American alligator has been basking but gets too hot, how might the alligator cool itself?

- a. increase vasodilation
- b. sweat
- c. move into shade
- d. increase metabolic rate

## Heat Conservation and Dissipation

Animals conserve or dissipate heat in a variety of ways. In certain climates, endothermic animals have some form of insulation, such as fur, fat, feathers, or some combination thereof. Animals with thick fur or feathers create an insulating layer of air between their skin and internal organs. Polar bears and seals live and swim in a subfreezing environment and yet maintain a constant, warm, body temperature. The arctic fox, for example, uses its fluffy tail as extra insulation when it curls up to sleep in cold weather. Mammals have a residual effect from shivering and increased muscle activity: arrector pili muscles cause “goose bumps,” causing small hairs to stand up when the individual is cold; this has the intended effect of increasing body temperature. Mammals use layers of fat to achieve the same end. Loss of significant amounts of body fat will compromise an individual’s ability to conserve heat.

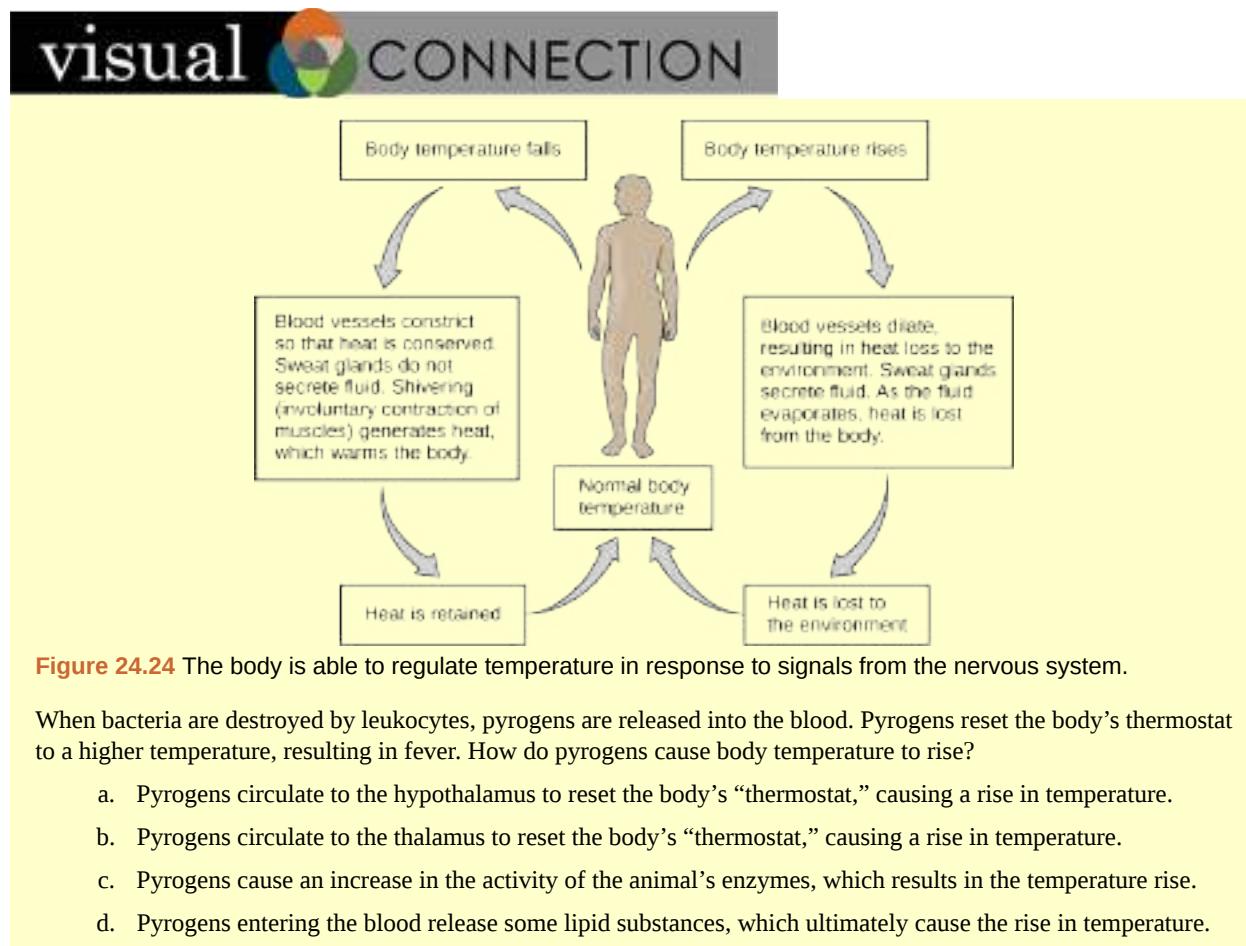

Endotherms use their circulatory systems to help maintain body temperature. Vasodilation brings more blood and heat to the body surface, facilitating radiation and evaporative heat loss, which helps to cool the body. Vasoconstriction reduces blood flow in peripheral blood vessels, forcing blood toward the core and the vital organs found there, and conserving heat. Some animals have adaptions to their circulatory system that enable them to transfer heat from arteries to veins, warming blood returning to the heart. This is called a countercurrent heat exchange; it prevents the cold venous blood from cooling the heart and other internal organs. This adaption can be shut down in some animals to prevent overheating the internal organs. The countercurrent adaption is found in many animals, including dolphins, sharks, bony fish, bees, and hummingbirds. In contrast, similar adaptations can help cool endotherms when needed, such as dolphin flukes and elephant ears.

Some ectothermic animals use changes in their behavior to help regulate body temperature. For example, a desert ectothermic animal may simply seek cooler areas during the hottest part of the day in the desert to keep from getting too warm. The same animals may climb onto rocks to capture heat during a cold desert night. Some animals seek water to aid evaporation in cooling them, as seen with reptiles. Other ectotherms use group activity such as the activity of bees to warm a hive to survive winter.

Many animals, especially mammals, use metabolic waste heat as a heat source. When muscles are contracted, most of the energy from the ATP used in muscle actions is wasted energy that translates into heat. Severe cold elicits a shivering reflex that generates heat for the body. Many species also have a type of adipose tissue called brown fat that specializes in generating heat.

## Neural Control of Thermoregulation

The nervous system is important to **thermoregulation**, as illustrated in [Figure 24.22](#). The processes of homeostasis and temperature control are centered in the hypothalamus of the advanced animal brain.

The hypothalamus maintains the set point for body temperature through reflexes that cause vasodilation and sweating when the body is too warm, or vasoconstriction and shivering when the body is too cold. It responds to chemicals from the body. When a bacterium is destroyed by phagocytic leukocytes, chemicals called endogenous pyrogens are released into the blood. These pyrogens circulate to the hypothalamus and reset the thermostat. This allows the body's temperature to increase in what is commonly called a fever. An increase in body temperature causes iron to be conserved, which reduces a nutrient needed by bacteria. An increase in body heat also increases the activity of the animal's enzymes and protective cells while inhibiting the enzymes and activity of the invading microorganisms. Finally, heat itself may also kill the pathogen. A fever that was once thought to be a complication of an infection is now understood to be a normal defense mechanism.

## KEY TERMS

**acclimatization** alteration in a body system in response to environmental change

**alteration** change of the set point in a homeostatic system

**apodeme** ingrowth of an animal's exoskeleton that functions as an attachment site for muscles

**asymmetrical** describes animals with no axis of symmetry in their body pattern

**basal metabolic rate (BMR)** metabolic rate at rest in endothermic animals

**canalculus** microchannel that connects the lacunae and aids diffusion between cells

**cartilage** type of connective tissue with a large amount of ground substance matrix, cells called chondrocytes, and some amount of fibers

**chondrocyte** cell found in cartilage

**columnar epithelia** epithelia made of cells taller than they are wide, specialized in absorption

**connective tissue** type of tissue made of cells, ground substance matrix, and fibers

**cuboidal epithelia** epithelia made of cube-shaped cells, specialized in glandular functions

**dorsal cavity** body cavity on the posterior or back portion of an animal; includes the cranial and vertebral cavities

**ectotherm** animal incapable of maintaining a relatively constant internal body temperature

**endotherm** animal capable of maintaining a relatively constant internal body temperature

**epithelial tissue** tissue that either lines or covers organs or other tissues

**estivation** torpor in response to extremely high temperatures and low water availability

**fibrous connective tissue** type of connective tissue with a high concentration of fibers

**frontal (coronal) plane** plane cutting through an animal separating the individual into front and back portions

**fusiform** animal body shape that is tubular and tapered at both ends

**hibernation** torpor over a long period of time, such as a winter

**homeostasis** dynamic equilibrium maintaining appropriate body functions

**lacuna** space in cartilage and bone that contains living cells

**loose (areolar) connective tissue** type of connective tissue with small amounts of cells, matrix, and fibers; found around blood vessels

**matrix** component of connective tissue made of both living and non-living (ground substances) cells

**midsagittal plane** plane cutting through an animal separating the individual into even right and left sides

**negative feedback loop** feedback to a control mechanism that increases or decreases a stimulus instead of maintaining it

**osteon** subunit of compact bone

**positive feedback loop** feedback to a control mechanism that continues the direction of a stimulus

**pseudostratified** layer of epithelia that appears multilayered, but is a simple covering

**sagittal plane** plane cutting through an animal separating the individual into right and left sides

**set point** midpoint or target point in homeostasis

**simple epithelia** single layer of epithelial cells

**squamous epithelia** type of epithelia made of flat cells, specialized in aiding diffusion or preventing abrasion

**standard metabolic rate (SMR)** metabolic rate at rest in ectothermic animals

**stratified epithelia** multiple layers of epithelial cells

**thermoregulation** regulation of body temperature

**torpor** decrease in activity and metabolism that allows an animal to survive adverse conditions

**trabecula** tiny plate that makes up spongy bone and gives it strength

**transitional epithelia** epithelia that can transition from simple to multilayered; also called uroepithelial

**transverse (horizontal) plane** plane cutting through an animal separating the individual into upper and lower portions

**ventral cavity** body cavity on the anterior or front portion of an animal that includes the thoracic cavities and the abdominopelvic cavities

## CHAPTER SUMMARY

### 24.1 Animal Form and Function

Animal bodies come in a variety of sizes and shapes. Limits on animal size and shape include impacts to their movement. Diffusion affects their size and development. Bioenergetics describes how animals use and obtain energy in relation to their body size, activity level, and environment.

### 24.2 Animal Primary Tissues

The basic building blocks of complex animals are four primary tissues. These are combined to form organs, which have a specific, specialized function within the body, such as the skin or kidney. Organs are organized together to perform common functions in the form of systems. The four primary tissues are epithelia, connective tissues, muscle tissues, and nervous tissues.

### 24.3 Homeostasis

Homeostasis is a dynamic equilibrium that is maintained in body tissues and organs. It is dynamic because it is constantly adjusting to the changes that the systems encounter. It is in equilibrium because body functions are kept within a normal range, with some fluctuations around a set point for the processes.

## REVIEW QUESTIONS

1. The pleural cavity is part of which cavity?
  - a. dorsal
  - b. thoracic
  - c. abdominal
  - d. pericardial
2. A plane that divides an animal into dorsal and ventral portions is the \_\_\_\_ plane.
  - a. sagittal
  - b. midsagittal
  - c. frontal
  - d. transverse
3. What is the term for a hard covering or shell that provides protection and muscle attachment?
  - a. apodeme
  - b. fusiform
  - c. exoskeleton
  - d. endotherm
4. Which organism has a fusiform shape?
  - a. elephant
  - b. dolphin
  - c. spider
  - d. human

**5.** Which type of animal maintains a constant internal body temperature?

- a. endotherm
- b. ectotherm
- c. poikilotherm
- d. fusiform

**6.** Smaller endothermic animals have \_\_\_\_\_ surface area for their mass compared with larger endothermic animals.

- a. equal
- b. greater
- c. less
- d. no

**7.** What is the term for epithelial cells that are composed of multiple layers?

- a. simple
- b. stratified
- c. squamous
- d. transitional

**8.** Which type of epithelial cell is best adapted to aid diffusion?

- a. squamous
- b. cuboidal
- c. columnar
- d. transitional

**9.** Why do osteoclasts need to break down bone?

- a. to deposit bone material into the bone matrix
- b. to facilitate osteoclast persistence without using excess energy
- c. to provide access to calcium in the tissue
- d. to facilitate compact bone structure

**10.** Plasma is the \_\_\_\_.

- a. fibers in the blood
- b. matrix of the blood
- c. cell that phagocytizes bacteria
- d. cell that functions in response to antigens

**11.** Why is it necessary for most muscle cells to be under voluntary control?

- a. to facilitate response to local conditions of tissues
- b. to facilitate movement of bone
- c. to speed up or slow down the autonomic nervous system
- d. to facilitate movement of internal organs

**12.** Cardiac muscle contains specialized regions along the

plasma membrane called intercalated discs. What is the role of intercalated discs?

- a. efficiently pass electrical impulses between cardiac cells
- b. facilitate immune response to foreign antigens
- c. cushion body organs from damage
- d. keeps blood vessels in place

**13.** The part of a neuron that contains the nucleus is the \_\_\_\_.

- a. axon
- b. dendrite
- c. cell body
- d. oligodendrocyte

**14.** Schwann cells or oligodendrocytes manufacture a lipid called myelin. Which statement best describes the function of this lipid?

- a. regulates the chemical environment
- b. sends input
- c. receives input
- d. improves signal transfer efficiency

**15.** Animals maintain an overall steady state of internal conditions by \_\_\_\_.

- a. ectothermy
- b. homeostasis
- c. basal metabolic rate
- d. standard metabolic rate

**16.** To what does the term “equilibrium” refer in the context of organismal homeostasis?

- a. control mechanisms that amplify a response
- b. control mechanisms that increase or decrease a stimulus
- c. the target point in homeostasis
- d. body functions are maintained within a given range

**17.** What type of feedback loop pushes an organism’s physiology further away from its normal setpoints?

- a. positive feedback loop
- b. negative feedback loop
- c. set point
- d. receptor

**18.** When faced with a sudden drop in environmental temperature, an endothermic animal will \_\_\_\_.

- a. experience a substantial drop in its body temperature
- b. find a warm rock on which to bask
- c. increase muscle activity to generate heat
- d. increase fur or fat to increase insulation

19. Homeostasis is primarily controlled by \_\_\_\_\_ feedback loops.

- a. positive
- b. negative
- c. acclimatization
- d. receptor

20. Which is an example of negative feedback?

- a. lowering of blood glucose after a meal
- b. blood clotting after an injury
- c. lactation during nursing
- d. uterine contractions during labor

## CRITICAL THINKING QUESTIONS

23. How does an asymmetrical body plan differ from radial or bilateral body plans?

- a. Asymmetrical organisms can produce equal halves if cut along a certain plane, whereas radially and bilaterally symmetric organisms have no distinct pattern.
- b. Asymmetrical organisms have no distinct pattern, whereas radially and bilaterally symmetric organisms can produce equal halves if cut along a certain plane.
- c. Asymmetrical organisms produce equal halves if cut along a certain plane with no definite right or left side, whereas radially and bilaterally symmetric organisms can produce equal halves.
- d. Asymmetrical organisms produce equal halves if cut along a certain plane with definite right and left sides, whereas radially and bilaterally symmetric organisms can produce equal halves.

24. Why are most organisms with exoskeletons relatively small?

21. Which method of heat exchange occurs during direct contact between the source and the animal?

- a. radiation
- b. evaporation
- c. convection
- d. conduction

22. Which of the following is a strategy that may be employed by an ectotherm to immediately increase body temperature?

- a. Consume more food to increase fat as insulation.
- b. Increase amount of vasodilation.
- c. Increase amount of muscle contraction.
- d. Sit on a warm rock.

a. Increases in body weight increase body size by a factor of eight, and the chitin thickness of the exoskeleton has to significantly decrease to accommodate increase in body size.

b. Doubling of body size increases body weight by a factor of eight, and the chitin thickness of the exoskeleton has to significantly decrease to accommodate weight increase.

c. Increases in body weight increase body size by a factor of eight, and the chitin thickness of the exoskeleton has to significantly increase to accommodate increase in body size.

d. Doubling of body size increases body weight by a factor of eight, and the chitin thickness of the exoskeleton has to significantly increase to accommodate weight increase.

25. What is the relationship between basal metabolic rate (BMR) and body size? Why?

- a. BMR decreases with body size, because larger animals require more energy to maintain their size. However, smaller animals have relatively higher BMRs per body weight because they have greater surface area.
- b. BMR increases with body size, because smaller animals require more energy to maintain their size. However, larger animals have relatively higher BMRs per body weight because they have greater surface area.
- c. BMR increases with body size, because larger animals require more energy to maintain their size. However, smaller animals have relatively higher BMRs per body weight because they have greater surface area for their mass.
- d. BMR decreases with body size, because smaller animals require more energy to maintain their size. However, larger animals have relatively higher BMRs per body weight because they have greater surface area for their mass.

**26.** Radial symmetry is typically found in aquatic organisms. What is radial symmetry and why is it advantageous to certain aquatic organisms?

- a. Radially symmetric means that a plane cut from the front to back of the organism produces distinct left and right sides that are mirror images of each other. It helps certain aquatic organisms to extract food from surrounding environments.
- b. Radially symmetric means that a plane cut from the front to back of the organism produces distinct left and right sides that are mirror images of each other. It helps certain aquatic organisms to perform photosynthesis.
- c. Radially symmetric means that a plane cut along its longitudinal axis will produce equal halves, and there is no distinct left or right. It helps certain aquatic organisms to perform photosynthesis.
- d. Radially symmetric means that a plane cut along its longitudinal axis to produce equal halves, and there is no distinct left or right. It helps certain aquatic organisms to extract food from surrounding environments.

**27.** Columnar epithelial cells, which are typically found in a single-layer arrangement, are found along the digestive tract. What is the role of columnar epithelial cells in digestion?

- a. Columnar epithelial cells absorb material from the lumen of the digestive tract to prepare the material for entry into the body.
- b. Columnar epithelial cells release mucus for lubrication as well as antimicrobial agents in the digestive tract.
- c. Columnar epithelial cells secrete enzymes like salivary amylase which aid in digestion by the breakdown of carbohydrates in the body.
- d. Columnar epithelial cells help in the propulsion of food by peristalsis in the digestive tract of the body.

**28.** In vertebrates, cartilage is found in fetal bones, ears, and intervertebral discs, whereas bone is found in the skeleton. What are the similarities between cartilage and bone?

- a. Both are types of connective tissue in the body and cells of both are known as chondrocytes.
- b. Both are types of connective tissue in the body and have non-vascular organic matrix material that provides strength and flexibility.
- c. Both are types of connective tissue in the body and have organic matrix material that provides strength and flexibility.
- d. Both consist of bone marrow and have organic matrix material that provides strength and flexibility.

**29.** A friend sneaks up behind you and scares you, speeding up your heart rate. How and why did this event influence cardiac muscle contraction?

- a. Muscle contraction speed increases as the enteric nervous system responds to local conditions and makes muscle contraction speed up or slow down.
- b. Muscle contraction speed increases as the autonomic nervous system responds to local conditions and makes muscle contraction speed up or slow down.
- c. Muscle contraction speed increases as the somatic nervous system responds to local conditions and makes muscle contraction speed up or slow down.
- d. Muscle contraction speed increases as the central nervous system responds to local conditions and makes muscle contraction speed up or slow down.

**30.** Neurons have several specialized structures, including dendrites. What might happen if an individual has malformed dendrites?

- a. The individual's neurons would not be able to receive input properly.
- b. The individual's neurons would not be able to synthesize proteins.
- c. The individual's neurons would not be able to communicate with target neurons.
- d. The individual's neurons would not be able to carry nerve signals.
- 31.** How can squamous epithelia, which have a high surface area-to-volume ratio, both facilitate diffusion and prevent damage from abrasion?
- a. Single layers of squamous epithelia facilitate gas, nutrient or waste exchange, whereas stratified layers provide protection but are not replaceable following damage.
- b. Stratified layers of squamous epithelia facilitate gas, nutrient or waste exchange, whereas single layers provide protection and are replaceable following damage.
- c. Single layers of squamous epithelia facilitate gas, nutrient or waste exchange whereas stratified layers provide protection and are replaceable following damage.
- d. Single layers of squamous epithelia facilitate only exchange of gases by diffusion, whereas stratified layers provide protection and are replaceable following damage.
- 32.** What is homeostasis and how does it help maintain equilibrium of various body functions throughout the body?
- a. Homeostasis is the process of achieving stability, which occurs through behavioral changes. Equilibrium is maintained by that ensuring body functions remain within a certain range.
- b. Homeostasis is the process by which constant adjustments to changes in the body occur, and equilibrium is maintained by ensuring that body functions remain within a certain range.
- c. Homeostasis is the process that prevents blood loss from circulation when a blood vessel is ruptured, and equilibrium is maintained by ensuring that circulation of blood is kept within a normal range.
- d. Homeostasis is the process by which constant adjustment to changes in the body occurs, and equilibrium is maintained as body functions remain within a certain range without any fluctuations.
- 33.** How can an environmental change result in an alteration of gland secretion?
- a. A receptor detects change, sends a signal to the control center, which sends a signal to the gland to inhibit the gland secretions.
- b. A receptor detects change, sends a signal to the control center, which sends a signal to the gland to increase the secretions of the gland.
- c. A receptor detects change and sends a signal to the effector directly ,which in this case is the gland.
- d. A receptor detects change, sends a signal to the control center, which in turn sends a signal to the effector, which in this case is the gland.
- 34.** How is a condition such as diabetes a good example of the failure of a set point in humans?
- a. A negative feedback loop cannot proceed in diabetic individuals, as they do not produce enough functional insulin to lower blood sugar.
- b. Negative feedback loop cannot proceed in diabetic individuals, as they do not produce enough functional insulin to increase the blood sugar.
- c. Positive feedback loop cannot proceed in diabetic individuals, as they do not produce enough functional insulin to lower blood sugar.
- d. Positive feedback loop cannot proceed in diabetic individuals, as they do not produce enough functional insulin to increase the blood sugar.
- 35.** What are the roles of vasodilation and vasoconstriction in maintaining body temperature?
- a. Vasodilation allows for radiation and evaporative heat loss, and vasoconstriction brings blood to the core to conserve heat by vital organs.
- b. Vasodilation brings blood to the core to conserve heat by vital organs, and vasoconstriction results in radiation and evaporative heat loss.
- c. Vasodilation results in the formation of an insulating layer between skin and internal organs causing heat conservation and brings blood to the core to conserve heat.
- d. Vasodilation results in radiation and evaporative heat loss, and vasoconstriction transfers heat from arteries to veins to warm blood returning to the heart.

## TEST PREP FOR AP® COURSES

- 36.** Maintaining body heat is important for maintaining body functions in animals. Which of the following

statements provides an example of how an animal can actively generate body heat?

- a. Triglycerides are used to store energy for later use.
- b. An animal produces metabolic waste energy in the form of heat.
- c. An animal has insulation, which helps it maintain a constant body temperature.
- d. An animal eats a large amount of high-fat foods to produce adipose tissue.

**37.** Ectotherms and endotherms have different strategies for generating and maintaining body heat. Explain why ectotherms are more dependent on the environment for body heat than endotherms and how endotherms are able to generate and maintain body temperature.

- a. Ectotherms use external thermal heat whereas endotherms use metabolically generated heat to help regulate and maintain body temperatures.
- b. Ectotherms use external heat to help regulate and maintain body temperatures whereas endotherms have constantly varying internal temperatures.
- c. Ectotherms use metabolically-generated heat to maintain a constant body temperature whereas endotherms use metabolically generated heat to regulate body temperature within a wider range.
- d. Ectotherms use external thermal energy to help regulate and maintain body temperatures whereas endotherms maintain a constant body temperature.

**38.** Which of the following statements most directly supports the claim that different species of organisms use different metabolic strategies to meet their energy requirements for growth, reproduction, and homeostasis?

- a. During cold periods, pond-dwelling animals can increase the number of unsaturated fatty acids in their cell membranes, while some plants make antifreeze proteins to prevent ice crystal formation in tissues.
- b. Bacteria lack introns, while many eukaryotic genes contain many of these intervening sequences.
- c. Carnivores have more teeth that are specialized for grinding food.
- d. Plants generally use starch molecules for storage while animals use glycogen and fats for storage.

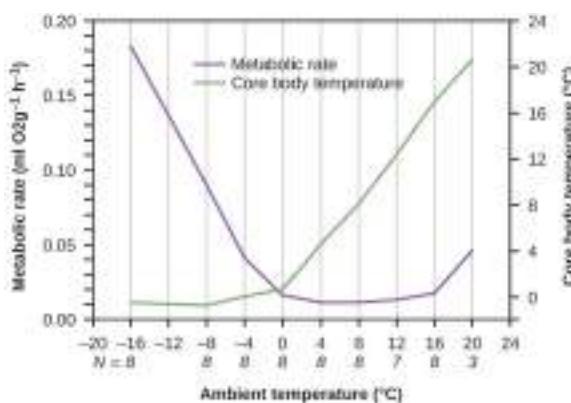

**39.** The body sizes of organisms vary and tends to be correlated with the region in which the organisms are found. Why do organisms at different latitudes tend to have different body sizes, and what is the relationship between heat loss and body size in an organism?

- a. Temperature varies by latitude, and body size affects heat retention and loss. Smaller organisms lose heat at a slower rate than larger organisms because they have a smaller surface area for their mass.
- b. Temperature varies by latitude, and body size affects heat retention and loss. Smaller organisms lose heat at a faster rate than larger organisms because they have a greater surface area for their mass.
- c. Temperature varies by latitude, and body size affects heat retention and loss. Larger organisms lose heat at a faster rate than smaller organisms because they have a greater surface area for their mass.
- d. Temperature varies by latitude, and body size affects heat retention and loss. Smaller organisms lose heat at a faster rate than larger organisms because they have a smaller surface area for their mass.

**40.** If an American alligator has been basking but gets too hot, how might the alligator cool itself?

- a. increase vasodilation
- b. sweat
- c. move into shade
- d. increase metabolic rate

**41.**

During torpor, arctic ground squirrels reduce their energy requirements by reducing their core body temperature and metabolic rate. Why would an active ground squirrel's ATP synthesis also increase in proportion to metabolic rate when temperatures fall below 0°?

- a. Colder temperatures causes ATP to degrade.
- b. ATP is synthesized through cellular respiration, which provides body heat.
- c. ATP synthesis is needed to provide more oxygen to the cells.
- d. ATP is consumed by the cells to generate body heat.

**42.** Why is hibernation not a good option for small animals like the hummingbirds to help reduce its metabolic rate and conserve its need for food?

- Hummingbirds have a fast metabolic rate and a large surface area to volume ratio.
- Hummingbirds are unable to lower their metabolic rate and body temperature to enter hibernation.
- Hummingbirds migrate south for the winter.
- Hummingbirds live a short life.

**43.** How does hibernation differ in small animals such as ground squirrels and larger animals such as bears?

- Smaller animals can engage in torpor while larger animals cannot.
- Larger animals can engage in torpor while smaller animals cannot.
- Smaller animals cannot remain inactive throughout the entire winter while larger animals can.
- Larger animals cannot remain inactive throughout the entire winter while smaller animals can.

**44.**

|          | Bear   | Marmot | Honey possum | Hummingbird | Shrew |
|----------|--------|--------|--------------|-------------|-------|
| BM (g)   | 80,000 | 4,000  | 10           | 4           | 2     |
| CD (min) | 8,307  | 1,766  | 80           | 59          | 35    |
| WU (min) | 741    | 237    | 24           | 17          | 13    |
| NBT (°C) | 37     | 40     | 37           | 40          | 34    |
| BTH (°C) | 33     | 18     | 5            | 2           | 2     |

In the data, BM = body mass, CD = cool-down time; WU = warm-up time, NBT = normal body temperature and BTH = body temperature during hibernation. What can you conclude from the data collected on five different animals as shown in the table above?

- The time it takes for animals to change body temperature is directly related to body size.
- The time it takes for animals to change their body temperature is indirectly related to their size.
- Larger animals hibernate for longer periods of time.
- Smaller animals hibernate for shorter periods of time

**45.**

|          | Bear   | Marmot | Honey possum | Hummingbird | Shrew |
|----------|--------|--------|--------------|-------------|-------|
| BM (g)   | 80,000 | 4,000  | 10           | 4           | 2     |
| CD (min) | 8,307  | 1,766  | 80           | 59          | 35    |
| WU (min) | 741    | 237    | 24           | 17          | 13    |
| NBT (°C) | 37     | 40     | 37           | 40          | 34    |
| BTH (°C) | 33     | 18     | 5            | 2           | 2     |

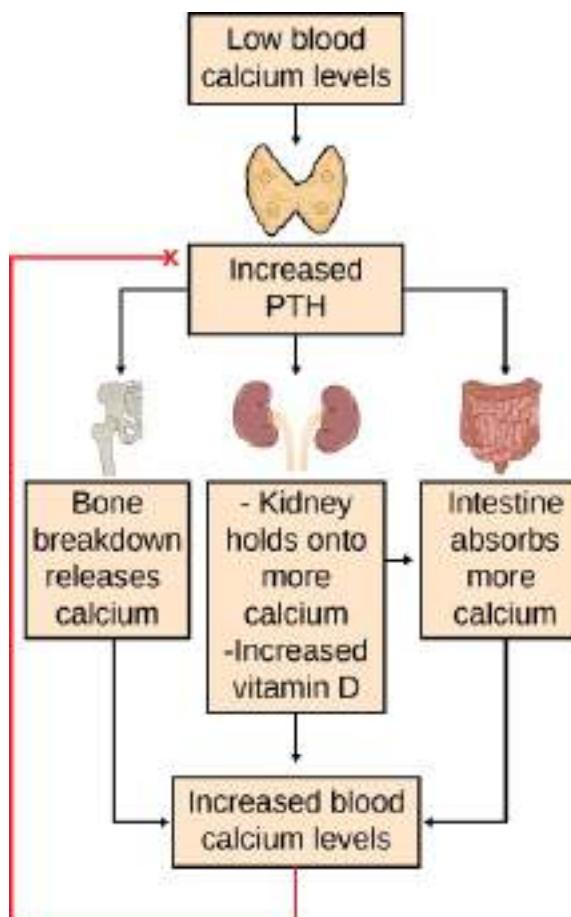

In the data, BM = body mass, CD = cool-down time; WU = warm-up time, NBT = normal body temperature and BTH = body temperature during hibernation. What can you conclude from about the time it takes to cool down versus the time it takes to warm up?

- a. Larger animals consume more energy to maintain their body temperatures.
- b. Smaller animals can survive hibernation with less food reserves than larger animals.
- c. Smaller animals require more time to alter their body temperature.
- d. Larger animals require more time to alter their body temperature.

**46.** The endocrine system incorporates feedback mechanisms that maintain homeostasis. Which of the following demonstrates negative feedback by the endocrine system?

- a. During labor, the fetus exerts pressure on the uterine wall, inducing the production of oxytocin, which stimulates uterine wall contraction. The contractions cause the fetus to further push on the wall, increasing the production of oxytocin.
- b. After a meal, blood glucose levels become elevated, stimulating beta cells of the pancreas to release insulin into the blood. Excess glucose is then converted to glycogen in the liver, reducing blood glucose levels.
- c. At high elevation, atmospheric oxygen is scarcer. In response to signals that oxygen is low, the brain decreases an individual's rate of respiration to compensate for the difference.
- d. A transcription factor binds to the regulating region of a gene, blocking the binding of another transcription factor required for expression.

**47.**

This figure depicts the process of calcium homeostasis. Describe how blood calcium control is an example of a negative feedback loop.

- a. Cells in parathyroid gland sense calcium decrease causing parathyroid hormone release and stimulating calcium absorption. Bone may also break down to release calcium.
- b. Cells in parathyroid gland sense calcium decrease causing calcitonin release and stimulating calcium absorption. Bone may also break down to release calcium.
- c. Cells in thyroid gland sense calcium decrease causing calcitonin release and stimulating calcium absorption. Bone may also break down to release calcium.
- d. Cells in parathyroid gland sense calcium increase causing parathyroid hormone release and stimulating calcium absorption. Bone may also break down to release calcium.

**48.** In organisms, homeostasis of various bodily processes, such as body temperature, blood glucose levels, and blood calcium levels, is essential for the maintenance of proper body functions. What role does insulin play in homeostasis?

- a. When a fetus pushes against the uterine wall, insulin is released by the brain to stimulate uterine contractions.
- b. In the presence of decreased blood glucose levels, insulin is produced by the parathyroid to increase calcium absorption.
- c. Insulin activation activates other clotting factors until a fibrin clot is produced.
- d. Insulin is secreted by the pancreas in response to elevated blood glucose levels to remove glucose from the blood.

**49.** Proper blood glucose levels are necessary to maintain cellular function, because glucose is fuel for cells.

Glucagon is an important component of blood glucose homeostasis, which is maintained by a negative feedback loop. Describe the role of glucagon in blood glucose homeostasis.

- a. When blood sugar is low, glucose and ATP produce glycogen. Excess blood sugar stimulates the release of glucagon, which in turn stimulates glycogen release to increase blood glucose levels.
- b. When there is excess blood sugar, excess glucose and ATP produce glucagon. A drop in blood glucose level stimulates the release of glycogen, which in turn stimulates glycogen release to increase blood glucose levels.
- c. When there is excess blood sugar, the excess glucose and ATP produce glycogen. A drop in blood glucose level stimulates the release of glucagon, which in turn stimulates the release of glycogen to increase blood glucose levels.
- d. When there is excess blood sugar, the excess glucose and ATP produce glycogen. A drop in blood glucose level stimulates the release of glucagon, which in turn releases more glucagon to increase blood glucose levels.

**50.** One process that is under the control of a negative feedback loop is red blood cell production. These cells carry oxygen to all of the body cells, and remove some carbon dioxide. What would most likely happen if an individual had a sufficient number of red blood cells?

- a. The individual would have increased red blood cell production.
- b. The individual's body would start destroying the red blood cells.
- c. The individual's body would cease production of new red blood cells.
- d. The individual would produce the same amount of red blood cells.

**51.** Diabetes results when either insulin cannot be produced or does not function properly. Consequently, diabetes can produce complications such as blindness,

heart disease, and kidney disease. To help manage diabetes, a patient can get insulin injections. How do insulin injections promote a negative feedback loop to help maintain blood glucose production?

- a. Insulin injections allow transport and storage of glucose to increase blood glucose levels after consuming a large or high-glucose meal.
- b. Insulin injections allow only storage of glucose to decrease blood glucose levels after consuming a large or high-glucose meal.
- c. Insulin injections allow transport and storage of glucose to increase blood glucose levels before consuming a meal.
- d. Insulin injections allow transport and storage of glucose to decrease blood glucose levels after consuming a large or high-glucose meal.

**52.** Positive feedback loops amplify processes in organisms. Which of the following statements describes the role of the hormone oxytocin in a positive feedback loop for childbirth?

- a. Oxytocin halts uterine contractions when the fetus pushes on the uterine wall.
- b. Oxytocin maintains pain levels as the child is pushed through the birth canal.
- c. Oxytocin stimulates uterine contractions when the fetus pushes on the uterine wall.
- d. Oxytocin decreases pain levels as the child is pushed through the birth canal.

**53.** Birth is one of the few positive feedback loops observed in humans and is essential for the proper delivery of babies. Describe how a baby pushing against a pregnant woman's cervix stimulates a positive feedback loop.

- a. Stretching stimulates nerve impulses to be sent to the brain, which releases oxytocin from the pituitary, which in turn causes uterine contractions.
- b. Stretching stimulates nerve impulses to be sent to the brain, which releases estrogen from the pituitary, which in turn causes uterine contractions.
- c. Stretching stimulates nerve impulses to be sent to the brain, which releases oxytocin from the parathyroid gland, which in turn causes uterine contractions.
- d. Stretching stimulates nerve impulses to be sent to the brain which releases progesterone from the pituitary, which in turn causes uterine contractions

**54.** Negative feedback mechanisms are far more prevalent in the human body than positive feedback loops because they help regulate homeostasis. However, there are some instances of positive feedback loops that can be observed in animals. Regulation of which of the following is an

example of a positive feedback loop?

- a. When body temperature gets too high, signals are sent to reduce body temperature.
  - b. Increased blood glucose levels stimulate insulin production, which in turn sequesters glucose from the blood.
  - c. Decreased calcium levels stimulate increased calcium absorption.
  - d. Activation of one clotting factor stimulates production of other clotting factors until a fibrin clot is produced.
55. Both negative and positive feedback loops are essential for maintaining proper body functions. Blood calcium and blood clotting are under the control of different feedback loops. Which of these processes is maintained by a positive feedback loop and why?

- a. Blood clotting is maintained by a positive feedback loop, as clotting is amplified in response by increasing the amount of clotting factors when clotting factors are present.
- b. Blood clotting is maintained by a positive feedback loop, as clotting factors are maintained in a specific range and a positive loop helps return the conditions to the set point.
- c. Blood calcium is maintained by a positive feedback loop, as calcium levels are amplified in response by increasing the amount of calcium levels when calcium is present.
- d. Blood calcium is maintained by a positive feedback loop, as calcium levels are maintained in a specific range and a positive feedback loop helps return the conditions to the set point.

# 25 | ANIMAL NUTRITION AND THE DIGESTIVE SYSTEM

**Figure 25.1** For humans, fruits and vegetables are important in maintaining a balanced diet. (credit: modification of work by Julie Rybarczyk)

## Chapter Outline

- 25.1: Digestive Systems**
- 25.2: Nutrition and Energy Production**
- 25.3: Digestive System Processes**
- 25.4: Digestive System Regulation**

## Introduction

All living organisms need nutrients to survive. Animals obtain their nutrients by the consumption of other organisms. At the cellular level, the biological molecules necessary for animal function are amino acids, lipid molecules, nucleotides, and simple sugars. However, the food consumed consists of protein, fat, and complex carbohydrates. Animals must convert these macromolecules into the simple molecules required for maintaining cellular functions, such as assembling new molecules, cells, and tissues. The conversion of the food consumed to the nutrients required is a multi-step process involving digestion and absorption. During digestion, food particles are broken down into smaller components; later, they are absorbed by the body.

One of the challenges in human nutrition is maintaining a balance between food intake, storage, and energy expenditure. Imbalances can have serious health consequences. For example, eating too much food while not expending much energy

leads to obesity; this in turn will increase the risk of developing illnesses such as type-2 diabetes and cardiovascular disease. The recent rise in obesity and related diseases makes understanding the role of diet and nutrition in maintaining good health all the more important. Many health experts believe that nutrition education will improve the overall health of the entire population. In fact, one nutrition education program, the Supplemental Nutrition Assistance Program (SNAP),<sup>[1]</sup> focused on preschool-aged children enrolled in a low-cost childcare setting and found that participating children were significantly more likely to eat more vegetables at home. You can read more about SNAP [here](http://openstaxcollege.org/l/32SNAP) (<http://openstaxcollege.org/l/32SNAP>)

## 25.1 | Digestive Systems

In this section, you will explore the following questions:

- What are the differences between digestion and absorption?
- What are different types of digestive systems in invertebrates and vertebrates?
- What are the specialized functions of the organs involved in processing food in the human body?
- How do organs work together to digest food and absorb nutrients?

### Connection for AP® Courses

Much information in this chapter is not within the scope of AP®. However, the chapter provides us with the opportunity to review concepts we've explored previously, including structure and function, macromolecules, energy production, transport of substances across membranes, and enzyme activity. All living organisms require a source of energy and molecules needed to build cells, tissues, and organs. During digestion, food is broken down into smaller molecules for absorption and distribution to all cells of the body. Nutrients are required to carry out cellular processes and maintain homeostasis, and digestion and absorption require the participation of several organs. Different animals have evolved different types of digestive systems specialized to meet their dietary needs. You do not need to memorize details about the different types of animal digestive systems, but you might find it interesting to explore the evolution of the system through a few groups of animals, from intracellular digestion in simple invertebrates to a digestive tract and accessory organs in complex vertebrates. Using a human eating a turkey sandwich as an example, food is ingested through the mouth. The mouth is the location where both mechanical (chewing) and chemical breakdown of food begins via the enzyme amylase, which breaks down carbohydrates into simpler sugars. The food bolus then travels by peristalsis (alternating waves of contraction) down the pharynx and esophagus to the stomach. In the stomach, pepsinogen mixes with hydrochloric acid to form pepsin, which begins digesting proteins, such as turkey, into smaller chains of amino acids. Mucus in the stomach protects its lining from damage by acidity, and the tightening of a sphincter prevents stomach contents from regurgitating into the esophagus. Further digestion of the ingredients of the sandwich occurs in the small intestine aided by a variety of enzymes; for example, bile salts and pancreatic amylase dumped into the small intestine from the gallbladder and pancreas, respectively, help emulsify fats. Once the ingredients of the sandwich have been broken down into smaller nutrient molecules, including amino acids, glucose, and fatty acids, they are absorbed from the small intestine into the circulatory and lymphatic systems. The walls of the small intestine contain small, finger-like projections called villi and microvilli that increase surface area for absorption of nutrients by diffusion. The large intestine or colon does not produce digestive enzymes but functions to absorb water, salts, and some vitamins. Any nutrients from the sandwich are stored in the liver, and wastes are eliminated.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 and Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A Learning Objective merges required content with one or more of the seven Science Practices.

|                   |                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Big Idea 2</b> | Biological systems utilize free energy and molecular building blocks to grow, to reproduce, and to maintain dynamic homeostasis. |

|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enduring Understanding</b><br><b>2.A</b> | Growth, reproduction and maintenance of living systems require free energy and matter.                                                                                         |
| <b>Essential Knowledge</b>                  | <b>2.A.3</b> Organisms must exchange matter with the environment to grow, reproduce and maintain organization.                                                                 |
| <b>Science Practice</b>                     | <b>2.2</b> The student can apply mathematical routines to quantities that describe natural phenomena.                                                                          |
| <b>Learning Objective</b>                   | <b>2.6</b> The student is able to use calculated surface area-to-volume ratios to predict which cell(s) might eliminate wastes or procure nutrients faster by diffusion.       |
| <b>Essential Knowledge</b>                  | <b>2.A.3</b> Organisms must exchange matter with the environment to grow, reproduce and maintain organization.                                                                 |
| <b>Science Practice</b>                     | <b>6.2</b> The student can construct explanations of phenomena based on evidence produced through scientific practices.                                                        |
| <b>Learning Objective</b>                   | <b>2.7</b> The student will be able to explain how cell size and shape affects the overall rate of nutrient intake and the rate of waste elimination.                          |
| <b>Big Idea 4</b>                           | Biological systems interact, and these systems and their interactions possess complex properties.                                                                              |
| <b>Enduring Understanding</b><br><b>4.A</b> | Interactions within biological systems lead to complex properties.                                                                                                             |
| <b>Essential Knowledge</b>                  | <b>4.A.4</b> Organisms exhibit complex properties due to interactions between their constituent parts.                                                                         |
| <b>Science Practice</b>                     | <b>3.3</b> The student can evaluate scientific questions.                                                                                                                      |
| <b>Learning Objective</b>                   | <b>4.8</b> The student is able to evaluate scientific questions concerning organisms that exhibit complex properties due to the interaction of their constituent parts.        |
| <b>Essential Knowledge</b>                  | <b>4.A.4</b> Organisms exhibit complex properties due to interactions between their constituent parts.                                                                         |
| <b>Science Practice</b>                     | <b>6.4</b> The student can make claims and predictions about natural phenomena based on scientific theories and models.                                                        |
| <b>Learning Objective</b>                   | <b>4.9</b> The student is able to predict the effects of a change in a component(s) of a biological system on the functionality of an organism(s).                             |
| <b>Essential Knowledge</b>                  | <b>4.A.4</b> Organisms exhibit complex properties due to interactions between their constituent parts.                                                                         |
| <b>Science Practice</b>                     | <b>1.3</b> The student can refine representations and models of natural or man-made phenomena and systems in the domain.                                                       |
| <b>Learning Objective</b>                   | <b>4.10</b> The student is able to refine representations and models to illustrate biocomplexity due to interactions of the constituent parts.                                 |
| <b>Enduring Understanding</b><br><b>4.B</b> | Competition and cooperation are important aspects of biological systems.                                                                                                       |
| <b>Essential Knowledge</b>                  | <b>4.B.2</b> Cooperative interactions within organisms promote efficiency in the use of energy and matter.                                                                     |
| <b>Science Practice</b>                     | <b>1.4</b> The student can use representations and models to analyze situations or solve problems qualitatively and quantitatively.                                            |
| <b>Learning Objective</b>                   | <b>4.18</b> The student is able to use representations and models to analyze how cooperative interactions within organisms promote efficiency in the use of matter and energy. |

Animals obtain their nutrition by consuming other organisms. Depending on their diet, animals can be classified into the following categories: plant eaters (herbivores), meat eaters (carnivores), and those that eat both plants and animals (omnivores). The nutrients and macromolecules present in food are not immediately accessible to the cells. There are a number of processes that modify food within the animal body to make the nutrients and organic molecules accessible for cellular function. As animals evolved in complexity of form and function, their digestive systems have also evolved to accommodate their various dietary needs.

## Herbivores, Omnivores, and Carnivores

**Herbivores** are animals whose primary food source is plant-based. Examples of herbivores, as shown in [Figure 25.2](#), include vertebrates like deer, koalas, and some bird species, as well as invertebrates such as crickets and caterpillars. These animals have evolved digestive systems capable of handling large amounts of plant material. Herbivores can be further classified into frugivores (fruit-eaters), granivores (seed eaters), nectivores (nectar feeders), and folivores (leaf eaters).

**Figure 25.2** Herbivores, like this (a) mule deer and (b) monarch caterpillar, eat primarily plant material. (credit a: modification of work by Bill Ebbesen; credit b: modification of work by Doug Bowman)

**Carnivores** are animals that eat other animals. The word carnivore is derived from Latin and literally means “meat eater.” Wild cats such as lions, shown in [Figure 25.3a](#) and tigers are examples of vertebrate carnivores, as are snakes and sharks, while invertebrate carnivores include sea stars, spiders, and ladybugs, shown in [Figure 25.3b](#). Obligate carnivores are those that rely entirely on animal flesh to obtain their nutrients; examples of obligate carnivores are members of the cat family, such as lions and cheetahs. Facultative carnivores are those that also eat non-animal food in addition to animal food. Note that there is no clear line that differentiates facultative carnivores from omnivores; dogs would be considered facultative carnivores.

**Figure 25.3** Carnivores like the (a) lion eat primarily meat. The (b) ladybug is also a carnivore that consumes small insects called aphids. (credit a: modification of work by Kevin Pluck; credit b: modification of work by Jon Sullivan)

**Omnivores** are animals that eat both plant- and animal-derived food. In Latin, omnivore means to eat everything. Humans, bears (shown in **Figure 25.4a**), and chickens are examples of vertebrate omnivores; invertebrate omnivores include cockroaches and crayfish (shown in **Figure 25.4b**).

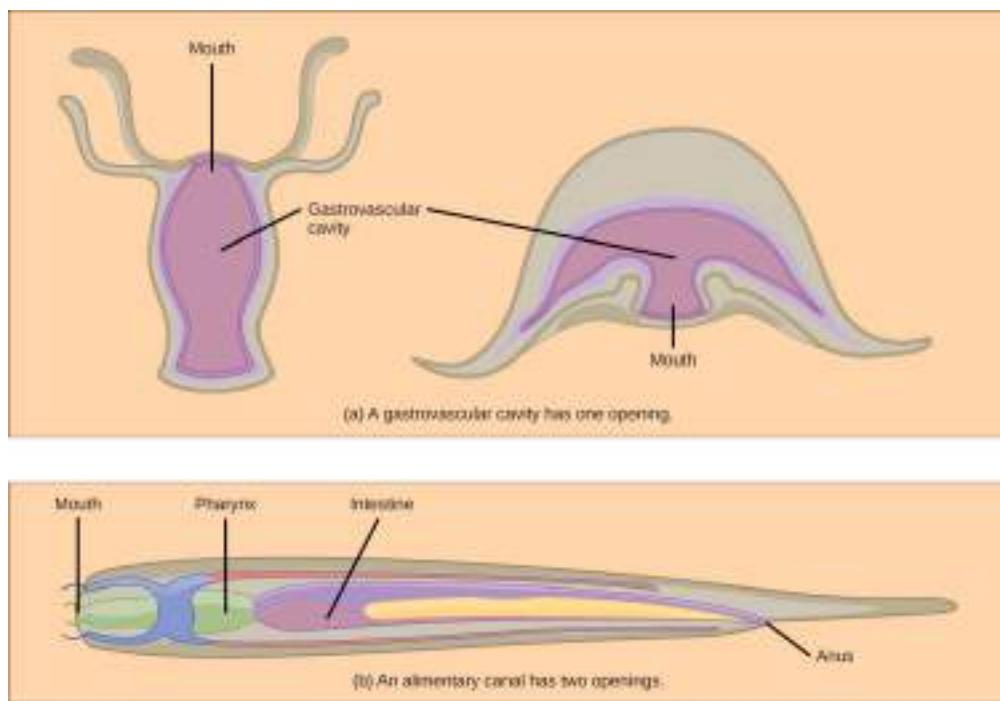

**Figure 25.4** Omnivores like the (a) bear and (b) crayfish eat both plant and animal based food. (credit a: modification of work by Dave Menke; credit b: modification of work by Jon Sullivan)

## Invertebrate Digestive Systems

Animals have evolved different types of digestive systems to aid in the digestion of the various foods they consume. The simplest example is that of a **gastrovascular cavity** and is found in organisms with only one opening for digestion. Platyhelminthes (flatworms), Ctenophora (comb jellies), and Cnidaria (coral, jelly fish, and sea anemones) use this type of digestion. Gastrovascular cavities, as shown in **Figure 25.5a**, are typically a blind tube or cavity with only one opening, the “mouth”, which also serves as an “anus”. Ingested material enters the mouth and passes through a hollow, tubular cavity. Cells within the cavity secrete digestive enzymes that break down the food. The food particles are engulfed by the cells lining the gastrovascular cavity.

The **alimentary canal**, shown in **Figure 25.5b**, is a more advanced system: it consists of one tube with a mouth at one end and an anus at the other. Earthworms are an example of an animal with an alimentary canal. Once the food is ingested through the mouth, it passes through the esophagus and is stored in an organ called the crop; then it passes into the gizzard where it is churned and digested. From the gizzard, the food passes through the intestine, the nutrients are absorbed, and the waste is eliminated as feces, called castings, through the anus.

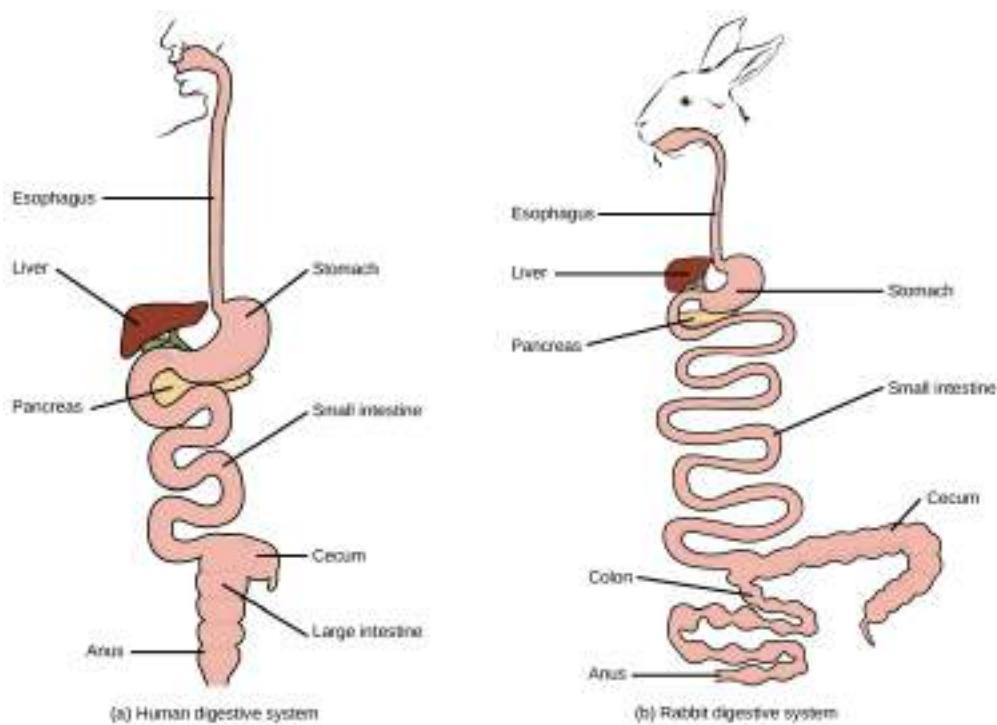

**Figure 25.5** (a) A gastrovascular cavity has a single opening through which food is ingested and waste is excreted, as shown in this hydra and in this jellyfish medusa. (b) An alimentary canal has two openings: a mouth for ingesting food, and an anus for eliminating waste, as shown in this nematode.

## Vertebrate Digestive Systems

Through evolution, vertebrate digestive systems have adapted to different diets. Some animals have a single stomach, while others have multi-chambered stomachs. Birds have developed a digestive system adapted to eating unmasticated food.

### **Monogastric: Single-chambered Stomach**

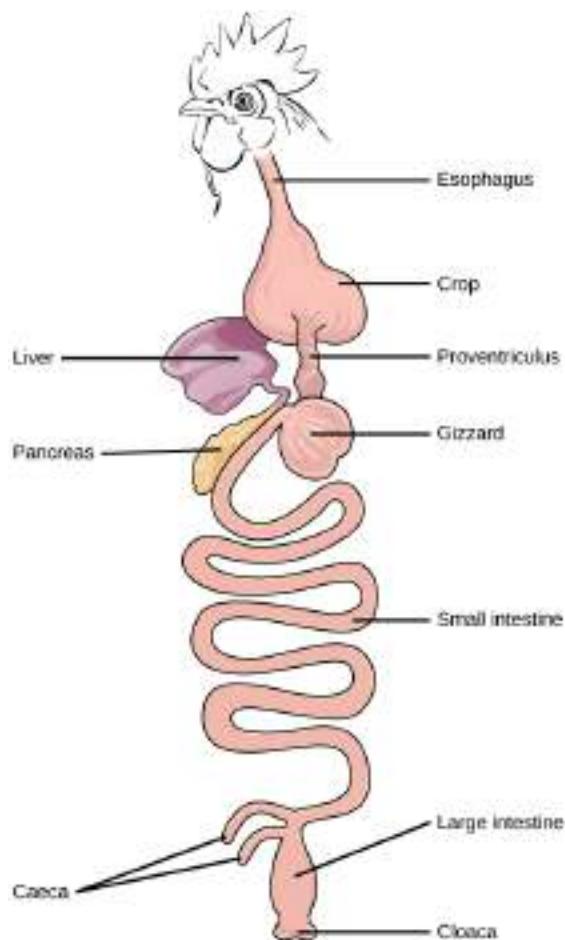

As the word **monogastric** suggests, this type of digestive system consists of one (“mono”) stomach chamber (“gastric”). Humans and many animals have a monogastric digestive system as illustrated in **Figure 25.6ab**. The process of digestion begins with the mouth and the intake of food. The teeth play an important role in masticating (chewing) or physically breaking down food into smaller particles. The enzymes present in saliva also begin to chemically break down food. The esophagus is a long tube that connects the mouth to the stomach. Using peristalsis, or wave-like smooth muscle contractions, the muscles of the esophagus push the food towards the stomach. In order to speed up the actions of enzymes in the stomach, the stomach is an extremely acidic environment, with a pH between 1.5 and 2.5. The gastric juices, which include enzymes in the stomach, act on the food particles and continue the process of digestion. Further breakdown of food takes place in the small intestine where enzymes produced by the liver, the small intestine, and the pancreas continue the process of digestion. The nutrients are absorbed into the blood stream across the epithelial cells lining the walls of the small intestines. The waste material travels on to the large intestine where water is absorbed and the drier waste material is compacted into feces; it is stored until it is excreted through the rectum.

**Figure 25.6** (a) Humans and herbivores, such as the (b) rabbit, have a monogastric digestive system. However, in the rabbit the small intestine and cecum are enlarged to allow more time to digest plant material. The enlarged organ provides more surface area for absorption of nutrients. Rabbits digest their food twice: the first time food passes through the digestive system, it collects in the cecum, and then it passes through the anus as soft feces called cecotrophes. The rabbit re-ingests these cecotrophes to further digest them.

### Avian

Birds face special challenges when it comes to obtaining nutrition from food. They do not have teeth and so their digestive system, shown in [Figure 25.7](#), must be able to process un-masticated food. Birds have evolved a variety of beak types that reflect the vast variety in their diet, ranging from seeds and insects to fruits and nuts. Because most birds fly, their metabolic rates are high in order to efficiently process food and keep their body weight low. The stomach of birds has two chambers: the **proventriculus**, where gastric juices are produced to digest the food before it enters the stomach, and the **gizzard**, where the food is stored, soaked, and mechanically ground. The undigested material forms food pellets that are sometimes regurgitated. Most of the chemical digestion and absorption happens in the intestine and the waste is excreted through the cloaca.

**Figure 25.7** The avian esophagus has a pouch, called a crop, which stores food. Food passes from the crop to the first of two stomachs, called the proventriculus, which contains digestive juices that break down food. From the proventriculus, the food enters the second stomach, called the gizzard, which grinds food. Some birds swallow stones or grit, which are stored in the gizzard, to aid the grinding process. Birds do not have separate openings to excrete urine and feces. Instead, uric acid from the kidneys is secreted into the large intestine and combined with waste from the digestive process. This waste is excreted through an opening called the cloaca.

# evolution CONNECTION

## Avian Adaptations

Birds have a highly efficient, simplified digestive system. Recent fossil evidence has shown that the evolutionary divergence of birds from other land animals was characterized by streamlining and simplifying the digestive system. Unlike many other animals, birds do not have teeth to chew their food. In place of lips, they have sharp pointy beaks. The horny beak, lack of jaws, and the smaller tongue of the birds can be traced back to their dinosaur ancestors. The emergence of these changes seems to coincide with the inclusion of seeds in the bird diet. Seed-eating birds have beaks that are shaped for grabbing seeds and the two-compartment stomach allows for delegation of tasks. Since birds need to remain light in order to fly, their metabolic rates are very high, which means they digest their food very quickly and need to eat often. Contrast this with the ruminants, where the digestion of plant matter takes a very long time.

Although both birds and humans are vertebrates, birds have a relatively higher metabolic rate than humans.

a. Why is the metabolic rate of birds relatively higher than that of humans?

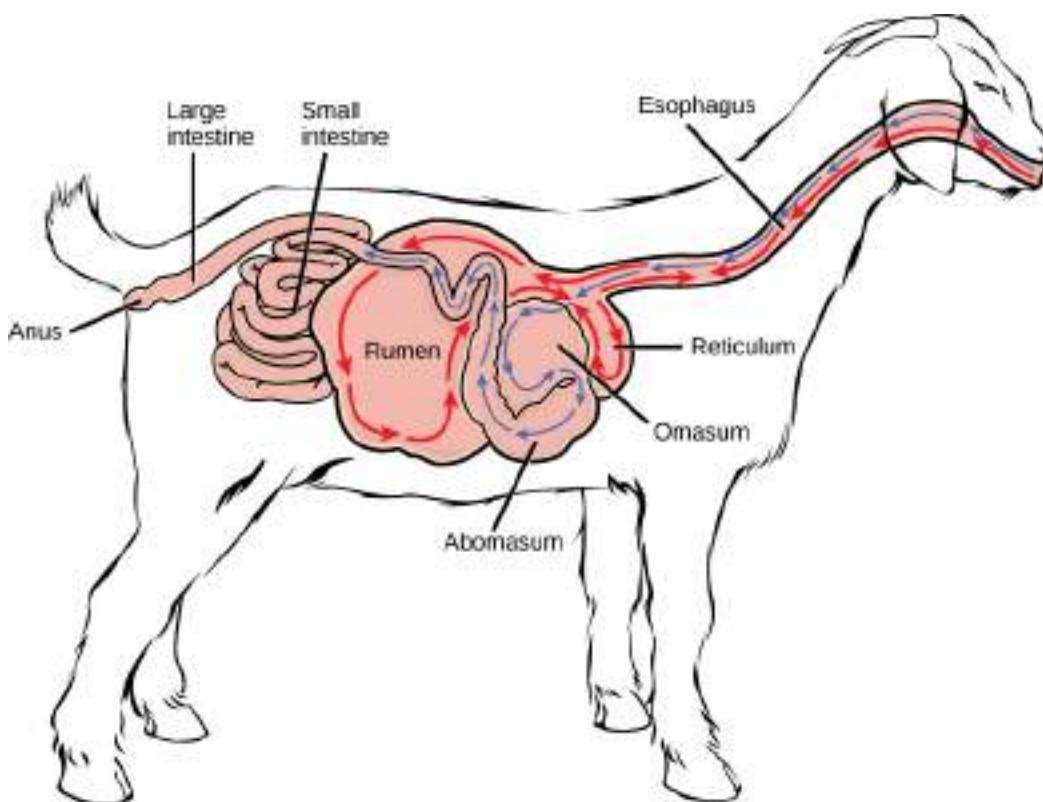

b. How do birds compensate for such a high metabolism?

- a. a. Birds have smaller surfaces to lose heat than humans, so their metabolic rate must be higher.  
b. Birds need to eat greater amounts of food since they digest food quickly.
- b. a. Birds need to be light to fly, so they need to digest their food faster than humans.  
b. Birds need to eat greater amounts of food since they digest food quickly.
- c. a. Birds have smaller surfaces to lose heat than humans, so their metabolic rate must be higher.  
b. Birds need to eat often to maintain energy since they digest food quickly.
- d. a. Birds need to be light to fly, so they need to digest their food faster than humans.  
b. Birds need to eat often to maintain energy since they digest food quickly.

## Ruminants

**Ruminants** are mainly herbivores like cows, sheep, and goats, whose entire diet consists of eating large amounts of **roughage** or fiber. They have evolved digestive systems that help them digest vast amounts of cellulose. An interesting feature of the ruminants' mouth is that they do not have upper incisor teeth. They use their lower teeth, tongue and lips to tear and chew their food. From the mouth, the food travels to the esophagus and on to the stomach.

To help digest the large amount of plant material, the stomach of the ruminants is a multi-chambered organ, as illustrated in **Figure 25.8**. The four compartments of the stomach are called the rumen, reticulum, omasum, and abomasum. These chambers contain many microbes that break down cellulose and ferment ingested food. The abomasum is the “true” stomach and is the equivalent of the monogastric stomach chamber where gastric juices are secreted. The four-compartment gastric chamber provides larger space and the microbial support necessary to digest plant material in ruminants. The fermentation process produces large amounts of gas in the stomach chamber, which must be eliminated. As in other animals, the small intestine plays an important role in nutrient absorption, and the large intestine helps in the elimination of waste.

**Figure 25.8** Ruminant animals, such as goats and cows, have four stomachs. The first two stomachs, the rumen and the reticulum, contain prokaryotes and protists that are able to digest cellulose fiber. The ruminant regurgitates cud from the reticulum, chews it, and swallows it into a third stomach, the omasum, which removes water. The cud then passes onto the fourth stomach, the abomasum, where it is digested by enzymes produced by the ruminant.

### Pseudo-ruminants

Some animals, such as camels and alpacas, are pseudo-ruminants. They eat a lot of plant material and roughage. Digesting plant material is not easy because plant cell walls contain the polymeric sugar molecule cellulose. The digestive enzymes of these animals cannot break down cellulose, but microorganisms present in the digestive system can. Therefore, the digestive system must be able to handle large amounts of roughage and break down the cellulose. Pseudo-ruminants have a three-chamber stomach in the digestive system. However, their cecum—a pouched organ at the beginning of the large intestine containing many microorganisms that are necessary for the digestion of plant materials—is large and is the site where the roughage is fermented and digested. These animals do not have a rumen but have an omasum, abomasum, and reticulum.

## Parts of the Digestive System

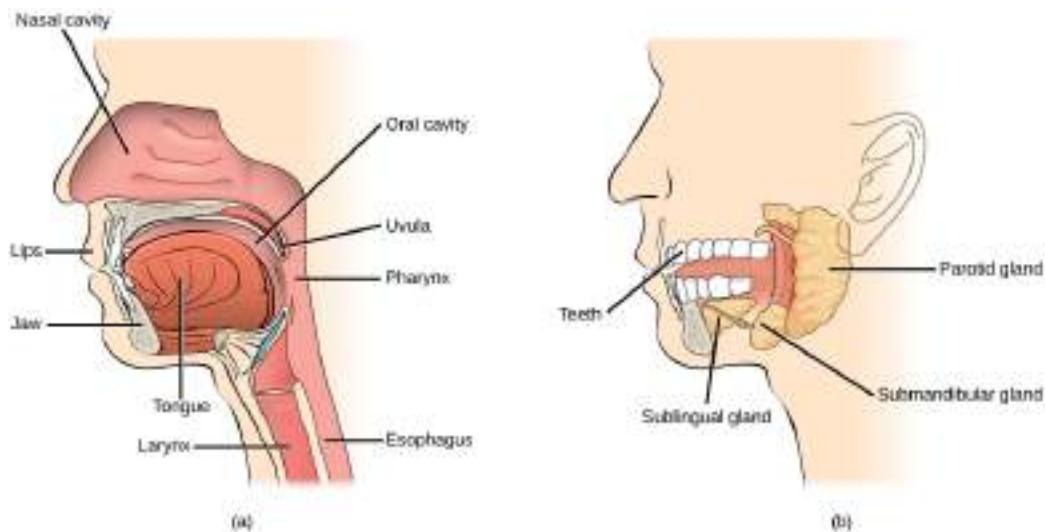

The vertebrate digestive system is designed to facilitate the transformation of food matter into the nutrient components that sustain organisms.

### Oral Cavity

The oral cavity, or mouth, is the point of entry of food into the digestive system, illustrated in **Figure 25.9**. The food consumed is broken into smaller particles by mastication, the chewing action of the teeth. All mammals have teeth and can chew their food.

The extensive chemical process of digestion begins in the mouth. As food is being chewed, saliva, produced by the salivary glands, mixes with the food. Saliva is a watery substance produced in the mouths of many animals. There are three major glands that secrete saliva—the parotid, the submandibular, and the sublingual. Saliva contains mucus that moistens food and buffers the pH of the food. Saliva also contains immunoglobulins and lysozymes, which have antibacterial action to reduce tooth decay by inhibiting growth of some bacteria. Saliva also contains an enzyme called **salivary amylase** that begins the process of converting starches in the food into a disaccharide called maltose. Another enzyme called **lipase** is produced by the cells in the tongue. Lipases are a class of enzymes that can break down triglycerides. The lingual lipase begins the breakdown of fat components in the food. The chewing and wetting action provided by the teeth and saliva prepare the food into a mass called the **bolus** for swallowing. The tongue helps in swallowing—moving the bolus from the mouth into the pharynx. The pharynx opens to two passageways: the trachea, which leads to the lungs, and the esophagus, which leads to

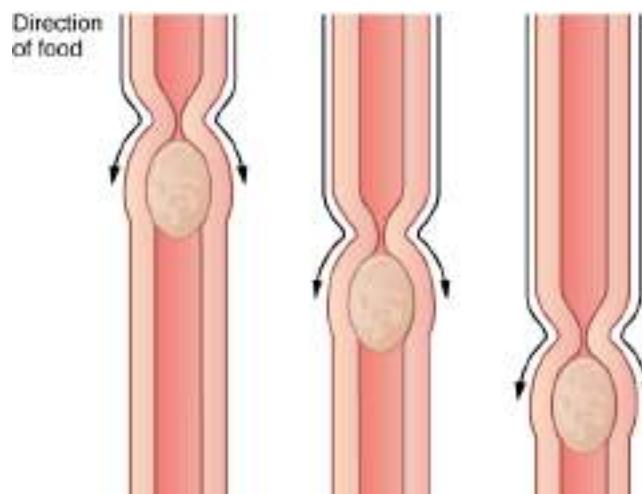

the stomach. The trachea has an opening called the glottis, which is covered by a cartilaginous flap called the epiglottis. When swallowing, the epiglottis closes the glottis and food passes into the esophagus and not the trachea. This arrangement allows food to be kept out of the trachea.

**Figure 25.9** Digestion of food begins in the (a) oral cavity. Food is masticated by teeth and moistened by saliva secreted from the (b) salivary glands. Enzymes in the saliva begin to digest starches and fats. With the help of the tongue, the resulting bolus is moved into the esophagus by swallowing. (credit: modification of work by the National Cancer Institute)

### Esophagus

The **esophagus** is a tubular organ that connects the mouth to the stomach. The chewed and softened food passes through the esophagus after being swallowed. The smooth muscles of the esophagus undergo a series of wave-like movements called **peristalsis** that push the food toward the stomach, as illustrated in [Figure 25.10](#). The peristaltic wave is unidirectional—it moves food from the mouth to the stomach, and reverse movement is not possible. The peristaltic movement of the esophagus is an involuntary reflex; it takes place in response to the act of swallowing.

**Figure 25.10** The esophagus transfers food from the mouth to the stomach through peristaltic movements.

A ring-like muscle called a **sphincter** forms valves in the digestive system. The gastro-esophageal sphincter is located at the stomach end of the esophagus. In response to swallowing and the pressure exerted by the bolus of food, this sphincter opens, and the bolus enters the stomach. When there is no swallowing action, this sphincter is shut and prevents the contents of the stomach from traveling up the esophagus. Many animals have a true sphincter; however, in humans, there is no true sphincter, but the esophagus remains closed when there is no swallowing action. Acid reflux or “heartburn” occurs when the acidic digestive juices escape into the esophagus.

### Stomach

A large part of digestion occurs in the stomach, shown in **Figure 25.11**. The **stomach** is a saclike organ that secretes gastric digestive juices. The pH in the stomach is between 1.5 and 2.5. This highly acidic environment is required for the chemical breakdown of food and the extraction of nutrients. When empty, the stomach is a rather small organ; however, it can expand to up to 20 times its resting size when filled with food. This characteristic is particularly useful for animals that need to eat when food is available.

### visual CONNECTION

The diagram illustrates the human digestive system with various organs labeled:

- Liver
- Gallbladder
- Stomach
- Pancreas
- Colon
- Transverse colon
- Ascending colon
- Descending colon
- Cecum
- Appendix
- Small Intestine
- Duodenum
- Jejunum
- Ileum
- Rectum
- Anus

Which of the following statements about the digestive system is true?

- Bile is a mixture of food and digestive juices that is produced in the stomach.
- Food enters the large intestine before the small intestine.
- In the small intestine, chyme mixes with bile, which emulsifies fats.
- The large intestines are separated from the small intestines by the pyloric sphincter.

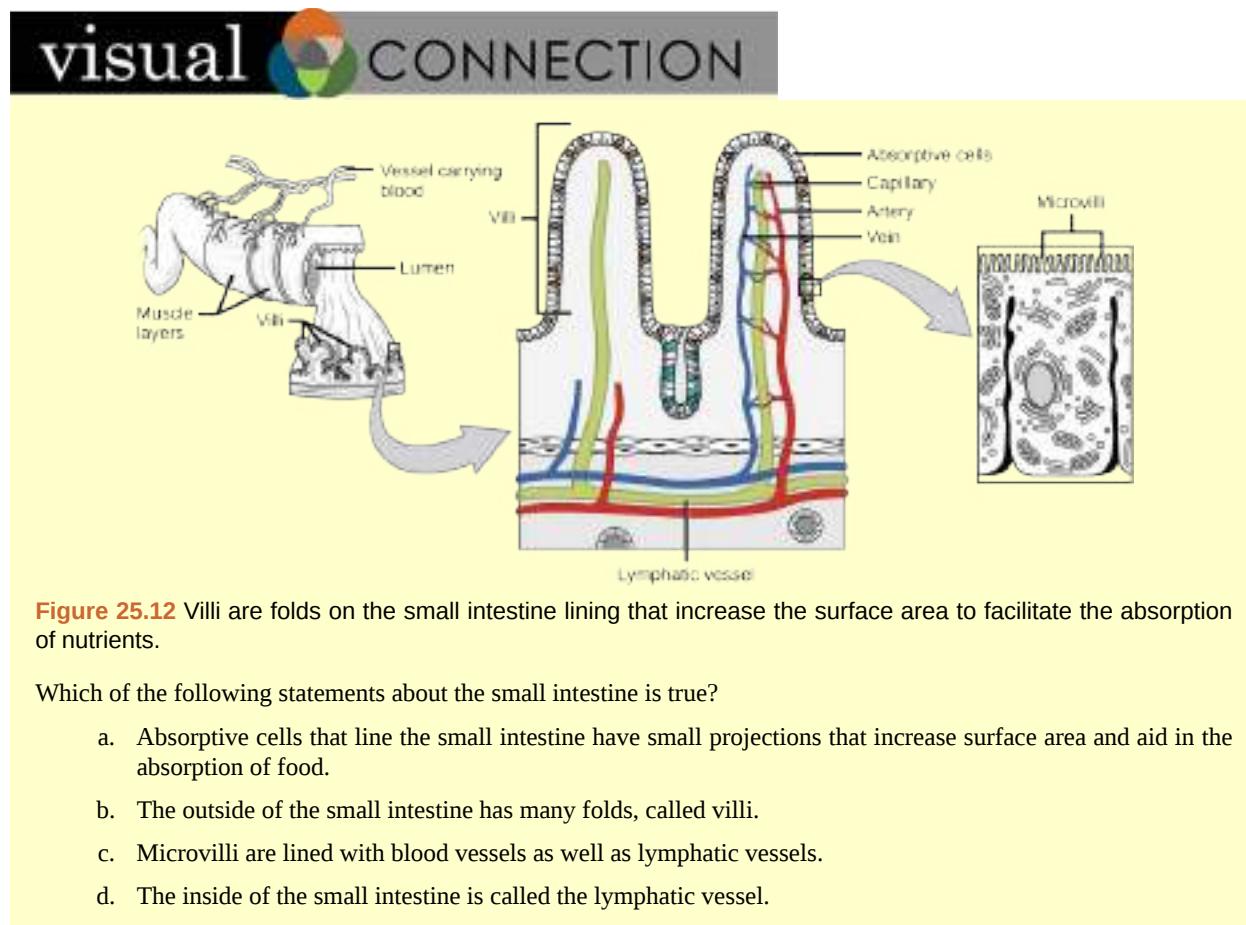

The stomach is the major site for protein digestion in animals other than ruminants. Protein digestion is mediated by an enzyme called pepsin in the stomach chamber. **Pepsin** is secreted by the chief cells in the stomach in an inactive form called **pepsinogen**. Pepsin breaks peptide bonds and cleaves proteins into smaller polypeptides; it also helps activate more pepsinogen, starting a positive feedback mechanism that generates more pepsin. Another cell type—parietal cells—secretes hydrogen and chloride ions, which combine in the lumen to form hydrochloric acid, the primary acidic component of the stomach juices. Hydrochloric acid helps to convert the inactive pepsinogen to pepsin. The highly acidic environment also kills many microorganisms in the food and, combined with the action of the enzyme pepsin, results in the hydrolysis of protein in the food. Chemical digestion is facilitated by the churning action of the stomach. Contraction and relaxation of smooth muscles mixes the stomach contents about every 20 minutes. The partially digested food and gastric juice mixture is called **chyme**. Chyme passes from the stomach to the small intestine. Further protein digestion takes place in the small intestine. Gastric emptying occurs within two to six hours after a meal. Only a small amount of chyme is released into the small intestine at a time. The movement of chyme from the stomach into the small intestine is regulated by the pyloric sphincter.

When digesting protein and some fats, the stomach lining must be protected from getting digested by pepsin. There are two points to consider when describing how the stomach lining is protected. First, as previously mentioned, the enzyme pepsin is synthesized in the inactive form. This protects the chief cells, because pepsinogen does not have the same enzyme functionality of pepsin. Second, the stomach has a thick mucus lining that protects the underlying tissue from the action of the digestive juices. When this mucus lining is ruptured, ulcers can form in the stomach. Ulcers are open wounds in or on

an organ caused by bacteria (*Helicobacter pylori*) when the mucus lining is ruptured and fails to reform.

### Small Intestine

Chyme moves from the stomach to the small intestine. The **small intestine** is the organ where the digestion of protein, fats, and carbohydrates is completed. The small intestine is a long tube-like organ with a highly folded surface containing finger-like projections called the **villi**. The apical surface of each villus has many microscopic projections called microvilli. These structures, illustrated in **Figure 25.12**, are lined with epithelial cells on the luminal side and allow for the nutrients to be absorbed from the digested food and absorbed into the blood stream on the other side. The villi and microvilli, with their many folds, increase the surface area of the intestine and increase absorption efficiency of the nutrients. Absorbed nutrients in the blood are carried into the hepatic portal vein, which leads to the liver. There, the liver regulates the distribution of nutrients to the rest of the body and removes toxic substances, including drugs, alcohol, and some pathogens.

**Figure 25.12** Villi are folds on the small intestine lining that increase the surface area to facilitate the absorption of nutrients.

Which of the following statements about the small intestine is true?

- Absorptive cells that line the small intestine have small projections that increase surface area and aid in the absorption of food.
- The outside of the small intestine has many folds, called villi.
- Microvilli are lined with blood vessels as well as lymphatic vessels.
- The inside of the small intestine is called the lymphatic vessel.

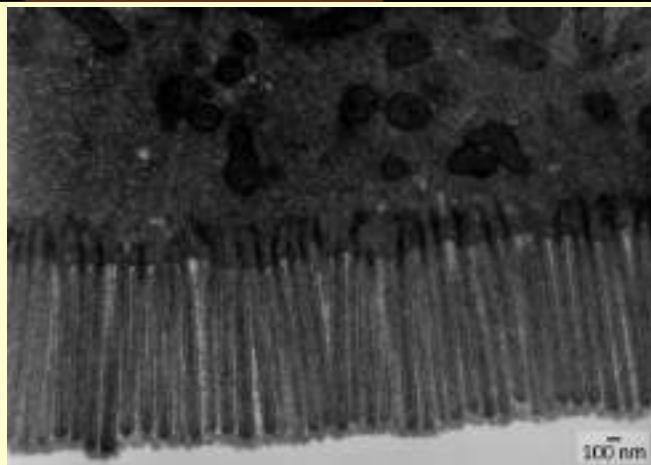

The human small intestine is over 6m long and is divided into three parts: the duodenum, the jejunum, and the ileum. The “C-shaped,” fixed part of the small intestine is called the **duodenum** and is shown in **Figure 25.11**. The duodenum is separated from the stomach by the pyloric sphincter which opens to allow chyme to move from the stomach to the duodenum. In the duodenum, chyme is mixed with pancreatic juices in an alkaline solution rich in bicarbonate that neutralizes the acidity of chyme and acts as a buffer. Pancreatic juices also contain several digestive enzymes. Digestive juices from the pancreas, liver, and gallbladder, as well as from gland cells of the intestinal wall itself, enter the duodenum. **Bile** is produced in the liver and stored and concentrated in the gallbladder. Bile contains bile salts which emulsify lipids while the pancreas produces enzymes that catabolize starches, disaccharides, proteins, and fats. These digestive juices break down the food particles in the chyme into glucose, triglycerides, and amino acids. Some chemical digestion of food takes place in the duodenum. Absorption of fatty acids also takes place in the duodenum.

The second part of the small intestine is called the **jejunum**, shown in **Figure 25.11**. Here, hydrolysis of nutrients is continued while most of the carbohydrates and amino acids are absorbed through the intestinal lining. The bulk of chemical digestion and nutrient absorption occurs in the jejunum.

The **ileum**, also illustrated in **Figure 25.11** is the last part of the small intestine and here the bile salts and vitamins are

absorbed into blood stream. The undigested food is sent to the colon from the ileum via peristaltic movements of the muscle. The ileum ends and the large intestine begins at the ileocecal valve. The vermiform, “worm-like,” appendix is located at the ileocecal valve. The appendix of humans secretes no enzymes and has an insignificant role in immunity.

## everyday CONNECTION for AP® Courses

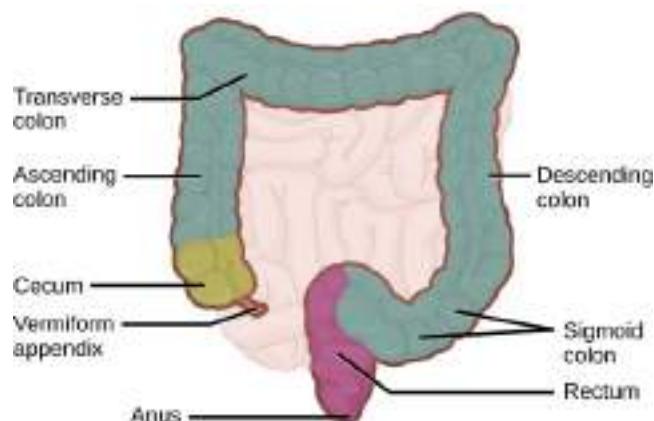

**Figure 25.13** Transmission electron microscope image of a thin section cut through an epithelial cell from a human jejunum (segment of the small intestine). The image shows the apical end of an absorptive cell with some of the densely packed microvilli that make up the striated border. Each microvillus is approximately 1  $\mu\text{m}$  long by 0.1  $\mu\text{m}$  in diameter and contains a core of actin microfilaments. (credit: “Microvilli”, Wikimedia Commons)

What is the role of microvilli in nutrient absorption?

- Microvilli form the inner layer of epithelial tissue in the small intestine and increase the absorption of nutrients from chyme.
- Microvilli are projections of absorptive cells that are involved in the absorption of bile salts and vitamin B12.
- Microvilli increase the surface area of absorptive cells, and therefore increase the amount of nutrients that can be absorbed.
- Microvilli use smooth muscle contractions to move the chyme, which contains nutrients, thereby increasing the rate of absorption.

### Large Intestine

The **large intestine**, illustrated in **Figure 25.14**, reabsorbs the water from the undigested food material and processes the waste material. The human large intestine is much smaller in length compared to the small intestine but larger in diameter. It has three parts: the cecum, the colon, and the rectum. The cecum joins the ileum to the colon and is the receiving pouch for the waste matter. The colon is home to many bacteria or “intestinal flora” that aid in the digestive processes. The colon can be divided into four regions, the ascending colon, the transverse colon, the descending colon and the sigmoid colon. The main functions of the colon are to extract the water and mineral salts from undigested food, and to store waste material. Carnivorous mammals have a shorter large intestine compared to herbivorous mammals due to their diet.

**Figure 25.14** The large intestine reabsorbs water from undigested food and stores waste material until it is eliminated.

### Rectum and Anus

The **rectum** is the terminal end of the large intestine, as shown in **Figure 25.14**. The primary role of the rectum is to store the feces until defecation. The feces are propelled using peristaltic movements during elimination. The **anus** is an opening at the far-end of the digestive tract and is the exit point for the waste material. Two sphincters between the rectum and anus control elimination: the inner sphincter is involuntary and the outer sphincter is voluntary.

### Accessory Organs

The organs discussed above are the organs of the digestive tract through which food passes. Accessory organs are organs that add secretions (enzymes) that catabolize food into nutrients. Accessory organs include salivary glands, the liver, the pancreas, and the gallbladder. The liver, pancreas, and gallbladder are regulated by hormones in response to the food consumed.

The **liver** is the largest internal organ in humans and it plays a very important role in digestion of fats and detoxifying blood. The liver produces bile, a digestive juice that is required for the breakdown of fatty components of the food in the duodenum. The liver also processes the vitamins and fats and synthesizes many plasma proteins.

The **pancreas** is another important gland that secretes digestive juices. The chyme produced from the stomach is highly acidic in nature; the pancreatic juices contain high levels of bicarbonate, an alkali that neutralizes the acidic chyme. Additionally, the pancreatic juices contain a large variety of enzymes that are required for the digestion of protein and carbohydrates.

The **gallbladder** is a small organ that aids the liver by storing bile and concentrating bile salts. When chyme containing fatty acids enters the duodenum, the bile is secreted from the gallbladder into the duodenum.

### Activity

Create a mini-poster that shows the procurement, digestion, absorption, and distribution of nutrients through the digestive systems of one invertebrate animal and one vertebrate animal. Explain how the organs of the system promote efficiency in the use of matter and energy.

### Think About It

Explain how the villi and microvilli aid in absorption of nutrients from the small intestine into the circulatory system.

## 25.2 | Nutrition and Energy Production

In this section, you will explore the following questions:

- Why must an animal have a balanced diet?
- What are the primary components of food?
- What are examples of essential nutrients required for cellular function that cannot be synthesized by the animal body?
- How is energy produced through diet and digestion?
- How are excess carbohydrates and energy stored in the body?

### Connection for AP<sup>®</sup> Courses

Much of the content described in this module is not within the scope of AP<sup>®</sup>. However, as we learn in the chapter on biological macromolecules, in animals the organic molecules required for building cellular materials and tissues come from food. During digestion, complex carbohydrates are broken down into glucose and used to provide energy through metabolic pathways, such as cellular respiration (see the chapter on cellular respiration). Excess sugars in the body are stored as glycogen in the liver and muscles for later use. Another important requirement is nitrogen, and protein catabolism provides a source of nitrogen; amino acids from protein breakdown are building blocks for new proteins. The carbon and nitrogen derived from amino acids also become building blocks for nucleic acids. Excess nitrogen is excreted because it is toxic. Although the animal body can synthesize many of the molecules necessary for function from organic precursors, some essential nutrients must be consumed from food. Vitamins are another class of essential organic molecules that are required in small quantities for many enzymes to function. (No, you do not need to memorize the table of vitamins and their functions!) Deficiencies in nutrients can have detrimental effects on an animal's health. For example, among other things, vitamin D is necessary for calcium absorption for bone development, and vitamin C is critical to multiple biochemical pathways, including immune function.

As we learn in the chapter on cellular respiration, animals need free energy, primarily supplied by carbohydrates, to maintain homeostasis. ATP is the energy currency of the cell and is produced by the oxidative reactions in the cytoplasm and mitochondria, where carbohydrates, proteins, and fats undergo a series of metabolic reactions collectively called cellular respiration. When the amount of ATP available exceeds the body's requirements, the liver uses the excess ATP and glucose to produce molecules of glycogen. The ability to store excess energy is an evolutionary adaptation that helps animals deal with mobility and food shortages.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP<sup>®</sup> Biology Curriculum Framework. The AP<sup>®</sup> Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP<sup>®</sup> Biology course, an inquiry-based laboratory experience, instructional activities, and AP<sup>®</sup> exam questions. A learning objective merges required content with one or more of the seven science practices.

Given the diversity of animal life on our planet, it is not surprising that the animal diet would also vary substantially. The animal diet is the source of materials needed for building DNA and other complex molecules needed for growth, maintenance, and reproduction; collectively these processes are called biosynthesis. The diet is also the source of materials for ATP production in the cells. The diet must be balanced to provide the minerals and vitamins that are required for cellular function.

## Food Requirements

What are the fundamental requirements of the animal diet? The animal diet should be well balanced and provide nutrients required for bodily function and the minerals and vitamins required for maintaining structure and regulation necessary for good health and reproductive capability. These requirements for a human are illustrated graphically in **Figure 25.15**

**Figure 25.15** For humans, a balanced diet includes fruits, vegetables, grains, and protein. (credit: USDA)

The first step in ensuring that you are meeting the food requirements of your body is an awareness of the food groups and the nutrients they provide. To learn more about each food group and the recommended daily amounts, explore this **interactive site** ([http://openstaxcollege.org/l/food\\_groups](http://openstaxcollege.org/l/food_groups)) by the United States Department of Agriculture.

How many cups of vegetables per day are recommended for a 61-year-old woman who does not exercise on a regular basis?

- a. 1.5 cups
- b. 2 cups
- c. 2.5 cups
- d. 3 cups

## everyday CONNECTION

### Let's Move! Campaign

Obesity is a growing epidemic and the rate of obesity among children is rapidly rising in the United States. To combat childhood obesity and ensure that children get a healthy start in life, former first lady Michelle Obama has launched the Let's Move! campaign. The goal of this campaign is to educate parents and caregivers on providing healthy nutrition and encouraging active lifestyles to future generations. This program aims to involve the entire community, including parents, teachers, and healthcare providers to ensure that children have access to healthy foods—more fruits, vegetables, and whole grains—and consume fewer calories from processed foods. Another goal is to ensure that children get physical activity. With the increase in television viewing and stationary pursuits such as video games, sedentary lifestyles have become the norm. Learn more at [www.letsmove.gov](http://www.letsmove.gov).

How does increased activity help reduce obesity in individuals?

- a. A more active individual will burn more calories.
- b. A more active individual will consume less fat.
- c. A more active individual will consume more calories.
- d. The appetite of a more active individual will be less.

### Organic Precursors

The organic molecules required for building cellular material and tissues must come from food. Carbohydrates or sugars are the primary source of organic carbons in the animal body. During digestion, digestible carbohydrates are ultimately broken down into glucose and used to provide energy through metabolic pathways. Complex carbohydrates, including polysaccharides, can be broken down into glucose through biochemical modification; however, humans do not produce the enzyme cellulase and lack the ability to derive glucose from the polysaccharide cellulose. In humans, these molecules provide the fiber required for moving waste through the large intestine and a healthy colon. The intestinal flora in the human gut are able to extract some nutrition from these plant fibers. The excess sugars in the body are converted into glycogen and stored in the liver and muscles for later use. Glycogen stores are used to fuel prolonged exertions, such as long-distance running, and to provide energy during food shortage. Excess glycogen can be converted to fats, which are stored in the lower layer of the skin of mammals for insulation and energy storage. Excess digestible carbohydrates are stored by mammals in order to survive famine and aid in mobility.

Another important requirement is that of nitrogen. Protein catabolism provides a source of organic nitrogen. Amino acids are the building blocks of proteins and protein breakdown provides amino acids that are used for cellular function. The carbon and nitrogen derived from these become the building block for nucleotides, nucleic acids, proteins, cells, and tissues. Excess nitrogen must be excreted as it is toxic. Fats add flavor to food and promote a sense of satiety or fullness. Fatty foods are also significant sources of energy because one gram of fat contains nine calories. Fats are required in the diet to aid the absorption of fat-soluble vitamins and the production of fat-soluble hormones.

### **Essential Nutrients**

While the animal body can synthesize many of the molecules required for function from the organic precursors, there are some nutrients that need to be consumed from food. These nutrients are termed **essential nutrients**, meaning they must be eaten, and the body cannot produce them.

The omega-3 alpha-linolenic acid and the omega-6 linoleic acid are essential fatty acids needed to make some membrane phospholipids. **Vitamins** are another class of essential organic molecules that are required in small quantities for many enzymes to function and, for this reason, are considered to be co-enzymes. Absence or low levels of vitamins can have a dramatic effect on health, as outlined in **Table 25.1** and **Table 25.2**. Both fat-soluble and water-soluble vitamins must be obtained from food. **Minerals**, listed in **Table 25.3**, are inorganic essential nutrients that must be obtained from food. Among their many functions, minerals help in structure and regulation and are considered co-factors. Certain amino acids also must be procured from food and cannot be synthesized by the body. These amino acids are the “essential” amino acids. The human body can synthesize only 11 of the 20 required amino acids; the rest must be obtained from food. The essential amino acids are listed in **Table 25.4**.

### **Water-soluble Essential Vitamins**

| Vitamin                                   | Function                                                                                                                                                                               | Deficiencies Can Lead To                                                                                                                                     | Sources                                          |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| Vitamin B <sub>1</sub> (Thiamine)         | Needed by the body to process lipids, proteins, and carbohydrates Coenzyme removes CO <sub>2</sub> from organic compounds                                                              | Muscle weakness, Beriberi: reduced heart function, CNS problems                                                                                              | Milk, meat, dried beans, whole grains            |
| Vitamin B <sub>2</sub> (Riboflavin)       | Takes an active role in metabolism, aiding in the conversion of food to energy (FAD and FMN)                                                                                           | Cracks or sores on the outer surface of the lips (cheliosis); inflammation and redness of the tongue; moist, scaly skin inflammation (seborrheic dermatitis) | Meat, eggs, enriched grains, vegetables          |
| Vitamin B <sub>3</sub> (Niacin)           | Used by the body to release energy from carbohydrates and to process alcohol; required for the synthesis of sex hormones; component of coenzyme NAD <sup>+</sup> and NADP <sup>+</sup> | Pellagra, which can result in dermatitis, diarrhea, dementia, and death                                                                                      | Meat, eggs, grains, nuts, potatoes               |
| Vitamin B <sub>5</sub> (Pantothenic acid) | Assists in producing energy from foods (lipids, in particular); component of coenzyme A                                                                                                | Fatigue, poor coordination, retarded growth, numbness, tingling of hands and feet                                                                            | Meat, whole grains, milk, fruits, vegetables     |
| Vitamin B <sub>6</sub> (Pyridoxine)       | The principal vitamin for processing amino acids and lipids; also helps convert nutrients into energy                                                                                  | Irritability, confusion, mouth sores or ulcers, anemia, muscular twitching                                                                                   | Meat, dairy products, whole grains, orange juice |
| Vitamin B <sub>7</sub> (Biotin)           | Used in energy and amino acid metabolism, fat synthesis, and fat breakdown; helps the body use blood sugar                                                                             | Hair loss, dermatitis, numbness and tingling in the extremities; neuromuscular disorders                                                                     | Meat, eggs, legumes and other vegetables         |

**Table 25.1**

### Water-soluble Essential Vitamins

| Vitamin                                | Function                                                                                                               | Deficiencies Can Lead To                                                                               | Sources                                                    |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| Vitamin B <sub>9</sub><br>(Folic acid) | Assists the normal development of cells, especially during fetal development; helps metabolize nucleic and amino acids | Deficiency during pregnancy is associated with birth defects, such as neural tube defects and anemia   | Leafy green vegetables, whole wheat, fruits, nuts, legumes |
| Vitamin B <sub>12</sub><br>(Cobalamin) | Maintains healthy nervous system and assists with blood cell formation; coenzyme in nucleic acid metabolism            | Anemia, neurological disorders, numbness, loss of balance                                              | Meat, eggs, animal products                                |
| Vitamin C<br>(Ascorbic acid)           | Helps maintain connective tissue: bone, cartilage, and dentin; boosts the immune system                                | Scurvy, which results in bleeding, hair and tooth loss; joint pain and swelling; delayed wound healing | Citrus fruits, broccoli, tomatoes, red sweet bell peppers  |

**Table 25.1**

### Fat-soluble Essential Vitamins

| Vitamin                      | Function                                                                                                                                                               | Deficiencies Can Lead To                                | Sources                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|----------------------------------------------------------------------------|
| Vitamin A<br>(Retinol)       | Critical to the development of bones, teeth, and skin; helps maintain eyesight, enhances the immune system, fetal development, gene expression                         | Night-blindness, skin disorders, impaired immunity      | Dark green leafy vegetables, yellow-orange vegetables fruits, milk, butter |
| Vitamin D                    | Critical for calcium absorption for bone development and strength; maintains a stable nervous system; maintains a normal and strong heartbeat; helps in blood clotting | Rickets, osteomalacia, immunity                         | Cod liver oil, milk, egg yolk                                              |
| Vitamin E<br>(Tocopherol)    | Lessens oxidative damage of cells, and prevents lung damage from pollutants; vital to the immune system                                                                | Deficiency is rare; anemia, nervous system degeneration | Wheat germ oil, unrefined vegetable oils, nuts, seeds, grains              |
| Vitamin K<br>(Phylloquinone) | Essential to blood clotting                                                                                                                                            | Bleeding and easy bruising                              | Leafy green vegetables, tea                                                |

**Table 25.2**

### Minerals and Their Function in the Human Body

| Mineral                    | Function                                                                                                                            | Deficiencies Can Lead To                                                   | Sources                                                                                        |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| *Calcium                   | Needed for muscle and neuron function; heart health; builds bone and supports synthesis and function of blood cells; nerve function | Osteoporosis, rickets, muscle spasms, impaired growth                      | Milk, yogurt, fish, green leafy vegetables, legumes                                            |
| *Chlorine                  | Needed for production of hydrochloric acid (HCl) in the stomach and nerve function; osmotic balance                                 | Muscle cramps, mood disturbances, reduced appetite                         | Table salt                                                                                     |
| Copper (trace amounts)     | Required component of many redox enzymes, including cytochrome c oxidase; cofactor for hemoglobin synthesis                         | Copper deficiency is rare                                                  | Liver, oysters, cocoa, chocolate, sesame, nuts                                                 |
| Iodine                     | Required for the synthesis of thyroid hormones                                                                                      | Goiter                                                                     | Seafood, iodized salt, dairy products                                                          |
| Iron                       | Required for many proteins and enzymes, notably hemoglobin, to prevent anemia                                                       | Anemia, which causes poor concentration, fatigue, and poor immune function | Red meat, leafy green vegetables, fish (tuna, salmon), eggs, dried fruits, beans, whole grains |
| *Magnesium                 | Required co-factor for ATP formation; bone formation; normal membrane functions; muscle function                                    | Mood disturbances, muscle spasms                                           | Whole grains, leafy green vegetables                                                           |
| Manganese (trace amounts)  | A cofactor in enzyme functions; trace amounts are required                                                                          | Manganese deficiency is rare                                               | Common in most foods                                                                           |
| Molybdenum (trace amounts) | Acts as a cofactor for three essential enzymes in humans: sulfite oxidase, xanthine oxidase, and aldehyde oxidase                   | Molybdenum deficiency is rare                                              |                                                                                                |

**Table 25.3**

## Minerals and Their Function in the Human Body

| Mineral                  | Function                                                                                                        | Deficiencies Can Lead To                              | Sources                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|-----------------------------------------|
| *Phosphorus              | A component of bones and teeth; helps regulate acid-base balance; nucleotide synthesis                          | Weakness, bone abnormalities, calcium loss            | Milk, hard cheese, whole grains, meats  |
| *Potassium               | Vital for muscles, heart, and nerve function                                                                    | Cardiac rhythm disturbance, muscle weakness           | Legumes, potato skin, tomatoes, bananas |
| Selenium (trace amounts) | A cofactor essential to activity of antioxidant enzymes like glutathione peroxidase; trace amounts are required | Selenium deficiency is rare                           | Common in most foods                    |
| *Sodium                  | Systemic electrolyte required for many functions; acid-base balance; water balance; nerve function              | Muscle cramps, fatigue, reduced appetite              | Table salt                              |
| Zinc (trace amounts)     | Required for several enzymes such as carboxypeptidase, liver alcohol dehydrogenase, and carbonic anhydrase      | Anemia, poor wound healing, can lead to short stature | Common in most foods                    |

\*Greater than 200mg/day required

**Table 25.3**

## Essential Amino Acids

| Amino acids that must be consumed |  | Amino acids anabolized by the body |
|-----------------------------------|--|------------------------------------|
| isoleucine                        |  | alanine                            |
| leucine                           |  | selenocysteine                     |
| lysine                            |  | aspartate                          |
| methionine                        |  | cysteine                           |
| phenylalanine                     |  | glutamate                          |
| tryptophan                        |  | glycine                            |
| valine                            |  | proline                            |
| histidine*                        |  | serine                             |
| threonine                         |  | tyrosine                           |
| arginine*                         |  | asparagine                         |

\*The human body can synthesize histidine and arginine, but not in the quantities required, especially for growing children.

**Table 25.4**

The logo for "science practices CONNECTION for AP Courses". The word "practices" is in a dark blue box with a magnifying glass icon over the letter "i". The word "CONNECTION" is in a light green box. The words "for AP Courses" are in a white box.

### Think About It

There are several nations where malnourishment is a common occurrence. What are some of the health challenges posed by malnutrition? What are examples of diseases caused by nutrient deficiencies?

## Food Energy and ATP

Animals need food to obtain energy and maintain homeostasis. Homeostasis is the ability of a system to maintain a stable internal environment even in the face of external changes to the environment. For example, the normal body temperature of humans is 37°C (98.6°F). Humans maintain this temperature even when the external temperature is hot or cold. It takes energy to maintain this body temperature, and animals obtain this energy from food.

The primary source of energy for animals is carbohydrates, mainly glucose. Glucose is called the body's fuel. The digestible carbohydrates in an animal's diet are converted to glucose molecules through a series of catabolic chemical reactions.

Adenosine triphosphate, or ATP, is the primary energy currency in cells; ATP stores energy in phosphate ester bonds. ATP releases energy when the phosphodiester bonds are broken and ATP is converted to ADP and a phosphate group. ATP is produced by the oxidative reactions in the cytoplasm and mitochondrion of the cell, where carbohydrates, proteins, and fats undergo a series of metabolic reactions collectively called cellular respiration. For example, glycolysis is a series of reactions in which glucose is converted to pyruvic acid and some of its chemical potential energy is transferred to NADH and ATP.

ATP is required for all cellular functions. It is used to build the organic molecules that are required for cells and tissues; it provides energy for muscle contraction and for the transmission of electrical signals in the nervous system. When the amount of ATP is available in excess of the body's requirements, the liver uses the excess ATP and excess glucose to produce molecules called glycogen. Glycogen is a polymeric form of glucose and is stored in the liver and skeletal muscle cells. When blood sugar drops, the liver releases glucose from stores of glycogen. Skeletal muscle converts glycogen to glucose during intense exercise. The process of converting glucose and excess ATP to glycogen and the storage of excess energy is an evolutionarily important step in helping animals deal with mobility, food shortages, and famine.

## everyday CONNECTION

### Obesity

Obesity is a major health concern in the United States, and there is a growing focus on reducing obesity and the diseases it may lead to, such as type-2 diabetes, cancers of the colon and breast, and cardiovascular disease. How does the food consumed contribute to obesity?

Fatty foods are calorie-dense, meaning that they have more calories per unit mass than carbohydrates or proteins. One gram of carbohydrates has four calories, one gram of protein has four calories, and one gram of fat has nine calories. Animals tend to seek lipid-rich food for their higher energy content.

The signals of hunger (“time to eat”) and satiety (“time to stop eating”) are controlled in the hypothalamus region of the brain. Foods that are rich in fatty acids tend to promote satiety more than foods that are rich only in carbohydrates.

Excess carbohydrate and ATP are used by the liver to synthesize glycogen. The pyruvate produced during glycolysis is used to synthesize fatty acids. When there is more glucose in the body than required, the resulting excess pyruvate is converted into molecules that eventually result in the synthesis of fatty acids within the body. These fatty acids are stored in adipose cells—the fat cells in the mammalian body whose primary role is to store fat for later use.

It is important to note that some animals benefit from obesity. Polar bears and seals need body fat for insulation and to keep them from losing body heat during Arctic winters. When food is scarce, stored body fat provides energy for maintaining homeostasis. Fats prevent famine in mammals, allowing them to access energy when food is not available on a daily basis; fats are stored when a large kill is made or lots of food is available.

Which of the following statements about obesity is true?

- a. Carbohydrate-rich foods satisfy hunger better than fatty acid-rich food.
- b. Obesity is disadvantageous for organisms that live in cold climates.
- c. Fat has more calories than protein or carbohydrates.
- d. In the presence of excess blood glucose, fatty acids are synthesized and stored in skeletal muscle.

## 25.3 | Digestive System Processes

In this section, you will explore the following questions:

- What is the process of digestion?
- What steps are involved in digestion and absorption?
- What is elimination?
- What are the roles of the small and large intestines in absorption?

### Connection for AP<sup>®</sup> Courses

Much of the information in this module is not within the scope of AP<sup>®</sup>. However, when we explored concepts about biological molecules in the chapter on biological macromolecules, we learned how macromolecules—carbohydrates, lipids, proteins, and nucleic acids—are synthesized from monomers. During digestion, these polymers are broken down into monomers, which are then absorbed and transported to all cells of the body. In the **Digestive Systems** module, we described the fate of the ingredients of a sandwich as they pass through the digestive tract. Food is ingested through the mouth, and digestion and absorption occur in a series of steps, with special enzymes playing important roles in digesting carbohydrates, proteins, and lipids. (You do not need to know the names of the specific enzymes involved in chemical digestion.) While most absorption of nutrients takes place in the small intestine, the remaining water, some vitamins, and any leftover salts are absorbed in the large intestine. Elimination describes the removal of undigested food.

Obtaining nutrition and energy from food is a multi-step process. For true animals, the first step is **ingestion**, the act of taking in food. This is followed by digestion, absorption, and elimination. In the following sections, each of these steps will be discussed in detail.

## Ingestion

The large molecules found in intact food cannot pass through the cell membranes. Food needs to be broken into smaller particles so that animals can harness the nutrients and organic molecules. The first step in this process is **ingestion**. Ingestion is the process of taking in food through the mouth. In vertebrates, the teeth, saliva, and tongue play important roles in mastication (preparing the food into bolus). While the food is being mechanically broken down, the enzymes in saliva begin to chemically process the food as well. The combined action of these processes modifies the food from large particles to a soft mass that can be swallowed and can travel the length of the esophagus.

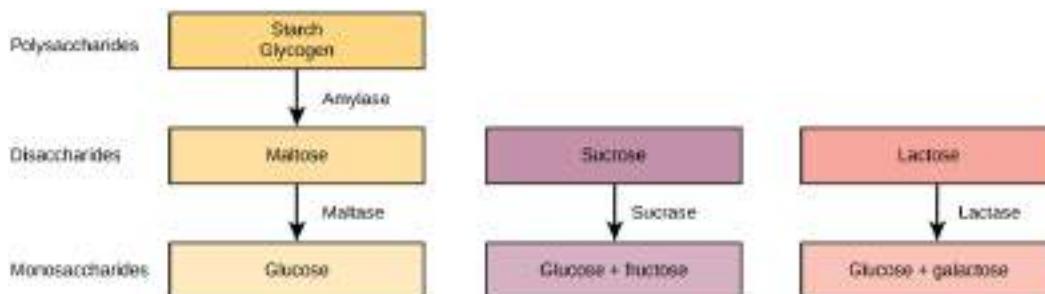

## Digestion and Absorption

**Digestion** is the mechanical and chemical break down of food into small organic fragments. It is important to break down macromolecules into smaller fragments that are of suitable size for absorption across the digestive epithelium. Large, complex molecules of proteins, polysaccharides, and lipids must be reduced to simpler particles such as simple sugar before they can be absorbed by the digestive epithelial cells. Different organs play specific roles in the digestive process. The animal diet needs carbohydrates, protein, and fat, as well as vitamins and inorganic components for nutritional balance. How each of these components is digested is discussed in the following sections.

### Carbohydrates

The digestion of carbohydrates begins in the mouth. The salivary enzyme amylase begins the breakdown of food starches into maltose, a disaccharide. As the bolus of food travels through the esophagus to the stomach, no significant digestion of carbohydrates takes place. The esophagus produces no digestive enzymes but does produce mucus for lubrication. The acidic environment in the stomach stops the action of the amylase enzyme.

The next step of carbohydrate digestion takes place in the duodenum. Recall that the chyme from the stomach enters the duodenum and mixes with the digestive secretion from the pancreas, liver, and gallbladder. Pancreatic juices also contain amylase, which continues the breakdown of starch and glycogen into maltose, a disaccharide. The disaccharides are broken down into monosaccharides by enzymes called **maltases**, **sucrases**, and **lactases**, which are also present in the brush border of the small intestinal wall. Maltase breaks down maltose into glucose. Other disaccharides, such as sucrose and lactose are broken down by sucrase and lactase, respectively. Sucrase breaks down sucrose (or “table sugar”) into glucose and fructose, and lactase breaks down lactose (or “milk sugar”) into glucose and galactose. The monosaccharides (glucose) thus produced are absorbed and then can be used in metabolic pathways to harness energy. The monosaccharides are transported across the intestinal epithelium into the bloodstream to be transported to the different cells in the body. The steps in carbohydrate digestion are summarized in **Figure 25.17** and **Table 25.5**.

**Figure 25.17** Digestion of carbohydrates is performed by several enzymes. Starch and glycogen are broken down into glucose by amylase and maltase. Sucrose (table sugar) and lactose (milk sugar) are broken down by sucrase and lactase, respectively.

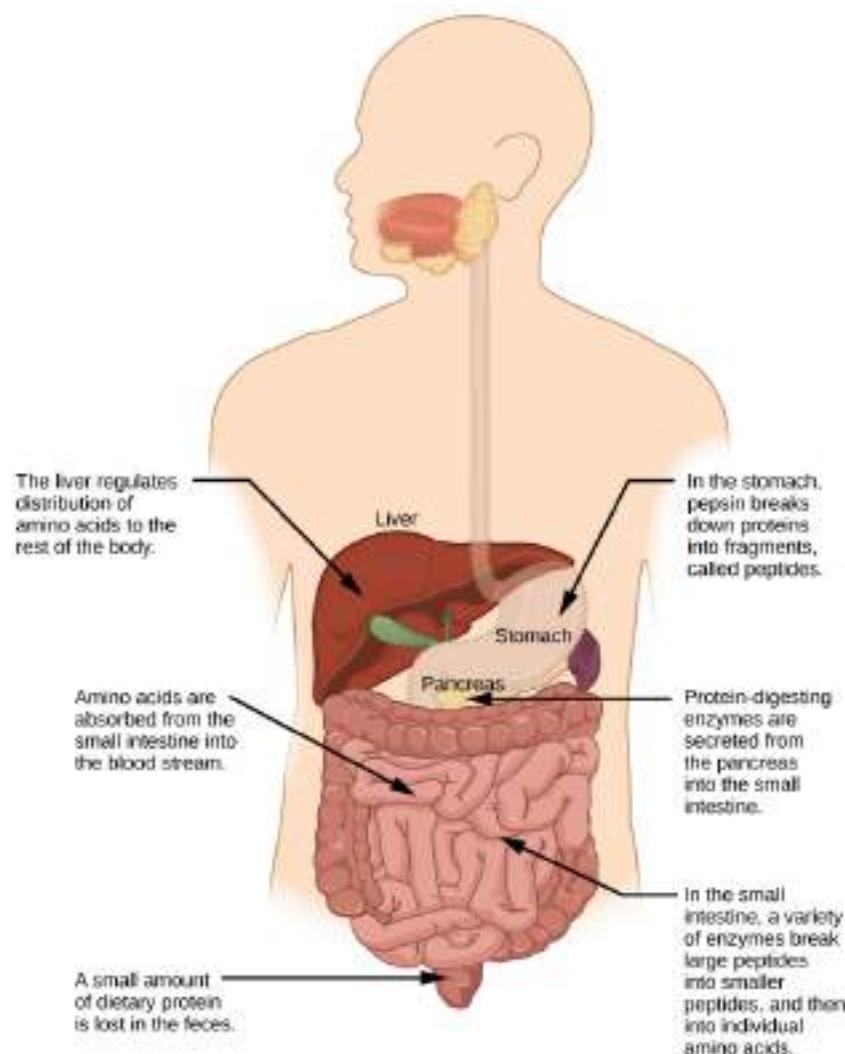

## Digestion of Carbohydrates

| Enzyme             | Produced By                                    | Site of Action  | Substrate Acting On      | End Products                                         |
|--------------------|------------------------------------------------|-----------------|--------------------------|------------------------------------------------------|
| Salivary amylase   | Salivary glands                                | Mouth           | Polysaccharides (Starch) | Disaccharides (maltose), oligosaccharides            |
| Pancreatic amylase | Pancreas                                       | Small intestine | Polysaccharides (starch) | Disaccharides (maltose), monosaccharides             |
| Oligosaccharidases | Lining of the intestine; brush border membrane | Small intestine | Disaccharides            | Monosaccharides (e.g., glucose, fructose, galactose) |

**Table 25.5**

### Protein

A large part of protein digestion takes place in the stomach. The enzyme pepsin plays an important role in the digestion of proteins by breaking down the intact protein to peptides, which are short chains of four to nine amino acids. In the duodenum, other enzymes—**trypsin**, **elastase**, and **chymotrypsin**—act on the peptides reducing them to smaller peptides. Trypsin elastase, carboxypeptidase, and chymotrypsin are produced by the pancreas and released into the duodenum where they act on the chyme. Further breakdown of peptides to single amino acids is aided by enzymes called peptidases (those that break down peptides). Specifically, **carboxypeptidase**, **dipeptidase**, and **aminopeptidase** play important roles in reducing the peptides to free amino acids. The amino acids are absorbed into the bloodstream through the small intestines. The steps in protein digestion are summarized in [Figure 25.18](#) and [Table 25.6](#).

**Figure 25.18** Protein digestion is a multistep process that begins in the stomach and continues through the intestines.

### Digestion of Protein

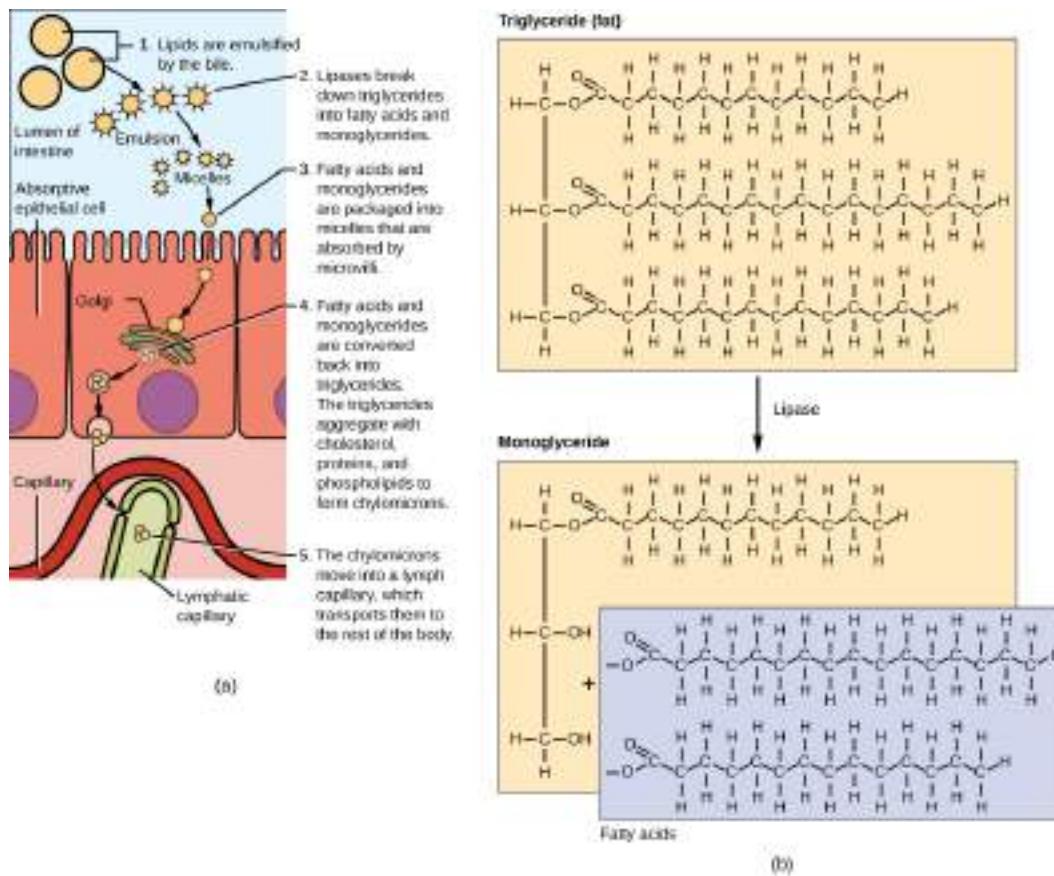

| Enzyme                              | Produced By         | Site of Action  | Substrate Acting On | End Products             |
|-------------------------------------|---------------------|-----------------|---------------------|--------------------------|
| Pepsin                              | Stomach chief cells | Stomach         | Proteins            | Peptides                 |
| Trypsin<br>Elastase<br>Chymotrypsin | Pancreas            | Small intestine | Proteins            | Peptides                 |
| Carboxypeptidase                    | Pancreas            | Small intestine | Peptides            | Amino acids and peptides |
| Aminopeptidase<br>Dipeptidase       | Lining of intestine | Small intestine | Peptides            | Amino acids              |

**Table 25.6**

## *Lipids*

Lipid digestion begins in the stomach with the aid of lingual lipase and gastric lipase. However, the bulk of lipid digestion occurs in the small intestine due to pancreatic lipase. When chyme enters the duodenum, the hormonal responses trigger the release of bile, which is produced in the liver and stored in the gallbladder. Bile aids in the digestion of lipids, primarily triglycerides by emulsification. Emulsification is a process in which large lipid globules are broken down into several small lipid globules. These small globules are more widely distributed in the chyme rather than forming large aggregates. Lipids are hydrophobic substances: in the presence of water, they will aggregate to form globules to minimize exposure to water. Bile contains bile salts, which are amphipathic, meaning they contain hydrophobic and hydrophilic parts. Thus, the bile salts hydrophilic side can interface with water on one side and the hydrophobic side interfaces with lipids on the other. By doing so, bile salts emulsify large lipid globules into small lipid globules.

Why is emulsification important for digestion of lipids? Pancreatic juices contain enzymes called lipases (enzymes that break down lipids). If the lipid in the chyme aggregates into large globules, very little surface area of the lipids is available for the lipases to act on, leaving lipid digestion incomplete. By forming an emulsion, bile salts increase the available surface area of the lipids many fold. The pancreatic lipases can then act on the lipids more efficiently and digest them, as detailed in **Figure 25.19**. Lipases break down the lipids into fatty acids and glycerides. These molecules can pass through the plasma membrane of the cell and enter the epithelial cells of the intestinal lining. The bile salts surround long-chain fatty acids and monoglycerides forming tiny spheres called micelles. The micelles move into the brush border of the small intestine absorptive cells where the long-chain fatty acids and monoglycerides diffuse out of the micelles into the absorptive cells leaving the micelles behind in the chyme. The long-chain fatty acids and monoglycerides recombine in the absorptive cells to form triglycerides, which aggregate into globules and become coated with proteins. These large spheres are called **chylomicrons**. Chylomicrons contain triglycerides, cholesterol, and other lipids and have proteins on their surface. The surface is also composed of the hydrophilic phosphate "heads" of phospholipids. Together, they enable the chylomicron to move in an aqueous environment without exposing the lipids to water. Chylomicrons leave the absorptive cells via exocytosis. Chylomicrons enter the lymphatic vessels, and then enter the blood in the subclavian vein.

**Figure 25.19** Lipids are digested and absorbed in the small intestine.

## **Vitamins**

Vitamins can be either water-soluble or lipid-soluble. Fat soluble vitamins are absorbed in the same manner as lipids. It is important to consume some amount of dietary lipid to aid the absorption of lipid-soluble vitamins. Water-soluble vitamins

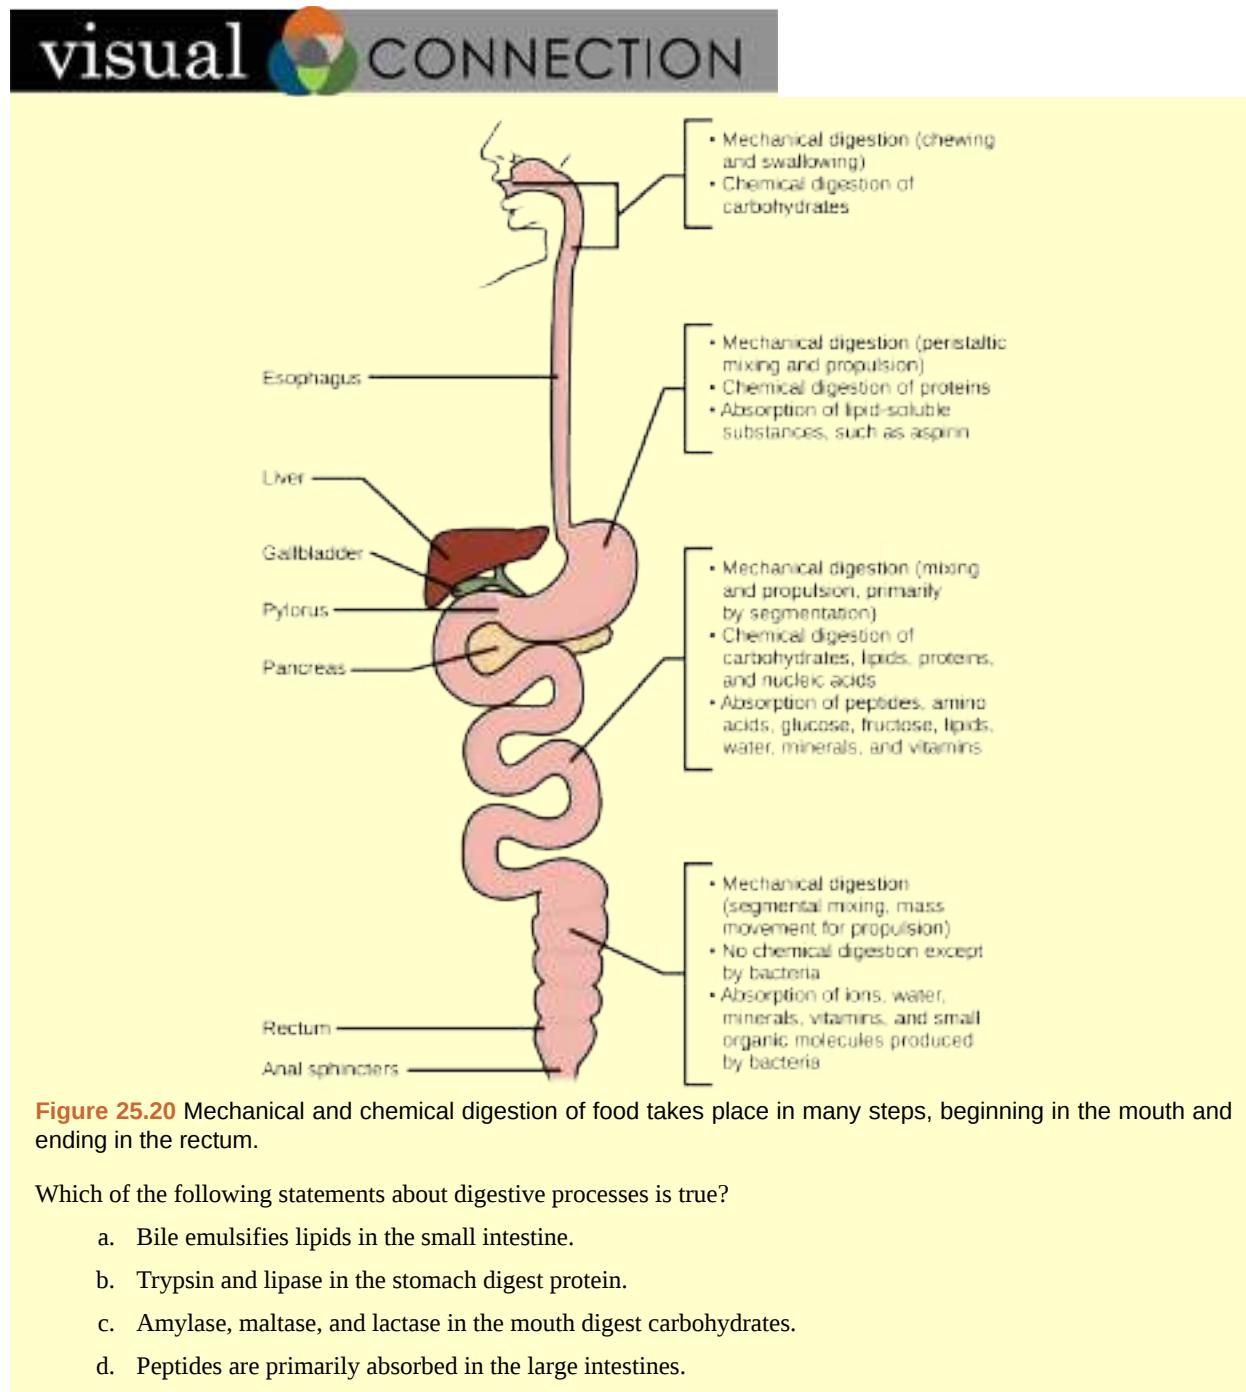

can be directly absorbed into the bloodstream from the intestine.

This **website** ([http://openstaxcollege.org/l/digest\\_enzymes](http://openstaxcollege.org/l/digest_enzymes)) has an overview of the digestion of protein, fat, and carbohydrates.

Which of the following events in digestion and absorption is incorrect?

- a. Carbohydrate digestion begins in the mouth.
- b. Protein is primarily digested in the stomach.
- c. Fats are primarily digested in the large intestine.
- d. Digested carbohydrate, fat, and protein molecules are absorbed by villi in the small intestine.

**Figure 25.20** Mechanical and chemical digestion of food takes place in many steps, beginning in the mouth and ending in the rectum.

Which of the following statements about digestive processes is true?

- Bile emulsifies lipids in the small intestine.
- Trypsin and lipase in the stomach digest protein.
- Amylase, maltase, and lactase in the mouth digest carbohydrates.
- Peptides are primarily absorbed in the large intestines.

## Elimination

The final step in digestion is the elimination of undigested food content and waste products. The undigested food material enters the colon, where most of the water is reabsorbed. Recall that the colon is also home to the microflora called “intestinal flora” that aid in the digestion process. The semi-solid waste is moved through the colon by peristaltic movements of the muscle and is stored in the rectum. As the rectum expands in response to storage of fecal matter, it triggers the neural signals required to set up the urge to eliminate. The solid waste is eliminated through the anus using peristaltic movements of the rectum.

### Common Problems with Elimination

Diarrhea and constipation are some of the most common health concerns that affect digestion. Constipation is a condition where the feces are hardened because of excess water removal in the colon. In contrast, if enough water is not removed from the feces, it results in diarrhea. Many bacteria, including the ones that cause cholera, affect the proteins involved in water reabsorption in the colon and result in excessive diarrhea.

### Emesis

Emesis, or vomiting, is elimination of food by forceful expulsion through the mouth. It is often in response to an irritant that affects the digestive tract, including but not limited to viruses, bacteria, emotions, sights, and food poisoning. This forceful expulsion of the food is due to the strong contractions produced by the stomach muscles. The process of emesis is regulated by the medulla.

## 25.4 | Digestive System Regulation

In this section, you will explore the following questions:

- How is neural regulation involved in the digestive processes?
- How do hormones regulate digestion?

### Connection for AP<sup>®</sup> Courses

The concepts presented in this module are not within the scope for AP<sup>®</sup> other than to note that the brain houses the control center for the sensation of hunger and satiety (fullness). The functions of the digestive system are regulated through neural and hormonal responses. In the chapter that discusses the endocrine system, we explore in detail the role of the endocrine system in maintaining homeostasis, including the normal functioning of the digestive system.

The brain is the control center for the sensation of hunger and satiety. The functions of the digestive system are regulated through neural and hormonal responses.

### Neural Responses to Food

In reaction to the smell, sight, or thought of food, like that shown in **Figure 25.21**, the first response is that of salivation. The salivary glands secrete more saliva in response to stimulation by the autonomic nervous system triggered by the food in preparation for digestion. Simultaneously, the stomach begins to produce hydrochloric acid to digest the food. Recall that the peristaltic movements of the esophagus and other organs of the digestive tract are under the control of the brain. The brain prepares these muscles for movement as well. When the stomach is full, the part of the brain that detects satiety signals fullness. There are three overlapping phases of gastric control—the cephalic phase, the gastric phase, and the intestinal phase—each requires many enzymes and is under neural control as well.

**Figure 25.21** Seeing a plate of food triggers the secretion of saliva in the mouth and the production of HCl in the stomach. (credit: Kelly Bailey)

### Digestive Phases

The response to food begins even before food enters the mouth. The first phase of ingestion, called the **cephalic phase**, is controlled by the neural response to the stimulus provided by food. All aspects—such as sight, sense, and smell—trigger the neural responses resulting in salivation and secretion of gastric juices. The gastric and salivary secretion in the cephalic phase can also take place due to the thought of food. Right now, if you think about a piece of chocolate or a crispy potato chip, the increase in salivation is a cephalic phase response to the thought. The central nervous system prepares the stomach to receive food.

The **gastric phase** begins once the food arrives in the stomach. It builds on the stimulation provided during the cephalic phase. Gastric acids and enzymes process the ingested materials. The gastric phase is stimulated by (1) distension of the stomach, (2) a decrease in the pH of the gastric contents, and (3) the presence of undigested material. This phase consists of local, hormonal, and neural responses. These responses stimulate secretions and powerful contractions.

The **intestinal phase** begins when chyme enters the small intestine triggering digestive secretions. This phase controls the rate of gastric emptying. In addition to gastric emptying, when chyme enters the small intestine, it triggers other hormonal and neural events that coordinate the activities of the intestinal tract, pancreas, liver, and gallbladder.

### Hormonal Responses to Food

The **endocrine system** controls the response of the various glands in the body and the release of hormones at the appropriate times.

One of the important factors under hormonal control is the stomach acid environment. During the gastric phase, the hormone **gastrin** is secreted by G cells in the stomach in response to the presence of proteins. Gastrin stimulates the release of stomach acid, or hydrochloric acid (HCl) which aids in the digestion of the proteins. However, when the stomach is emptied, the acidic environment need not be maintained and a hormone called **somatostatin** stops the release of hydrochloric acid. This is controlled by a negative feedback mechanism.

In the duodenum, digestive secretions from the liver, pancreas, and gallbladder play an important role in digesting chyme during the intestinal phase. In order to neutralize the acidic chyme, a hormone called **secretin** stimulates the pancreas to produce alkaline bicarbonate solution and deliver it to the duodenum. Secretin acts in tandem with another hormone called **cholecystokinin** (CCK). Not only does CCK stimulate the pancreas to produce the requisite pancreatic juices, it also stimulates the gallbladder to release bile into the duodenum.

Visit [this website \(\[http://openstaxcollege.org/l/enteric\\\_endo\]\(http://openstaxcollege.org/l/enteric\_endo\)\)](http://openstaxcollege.org/l/enteric_endo) to learn more about the endocrine system. Review the text and watch the animation of how control is implemented in the endocrine system.

Which of the following statements about the enteric endocrine system is true?

- a. Gastrin stimulates pancreatic enzyme and bile secretion.
- b. The enteric endocrine system includes all endocrine cells of the gastrointestinal tract.
- c. All hormone-secreting cells in the enteric endocrine system are clustered together.
- d. Enteric endocrine system cells secrete enzymes in response to specific stimuli.

Another level of hormonal control occurs in response to the composition of food. Foods high in lipids take a long time to digest. A hormone called **gastric inhibitory peptide** is secreted by the small intestine to slow down the peristaltic movements of the intestine to allow fatty foods more time to be digested and absorbed.

Understanding the hormonal control of the digestive system is an important area of ongoing research. Scientists are exploring the role of each hormone in the digestive process and developing ways to target these hormones.

## KEY TERMS

- alimentary canal** tubular digestive system with a mouth and anus
- aminopeptidase** protease that breaks down peptides to single amino acids; secreted by the brush border of small intestine
- anus** exit point for waste material
- bile** digestive juice produced by the liver; important for digestion of lipids
- bolus** mass of food resulting from chewing action and wetting by saliva
- carboxypeptidase** protease that breaks down peptides to single amino acids; secreted by the brush border of the small intestine
- carnivore** animal that consumes animal flesh
- cephalic phase** first phase of digestion, controlled by the neural response to the stimulus provided by food
- cholecystokinin** hormone that stimulates the contraction of the gallbladder to release bile
- chylomicron** small lipid globule
- chyme** mixture of partially digested food and stomach juices
- chymotrypsin** pancreatic protease
- digestion** mechanical and chemical break down of food into small organic fragments
- dipeptidase** protease that breaks down peptides to single amino acids; secreted by the brush border of small intestine
- duodenum** first part of the small intestine where a large part of digestion of carbohydrates and fats occurs
- elastase** pancreatic protease
- endocrine system** system that controls the response of the various glands in the body and the release of hormones at the appropriate times
- esophagus** tubular organ that connects the mouth to the stomach
- essential nutrient** nutrient that cannot be synthesized by the body; it must be obtained from food
- gallbladder** organ that stores and concentrates bile
- gastric inhibitory peptide** hormone secreted by the small intestine in the presence of fatty acids and sugars; it also inhibits acid production and peristalsis in order to slow down the rate at which food enters the small intestine
- gastric phase** digestive phase beginning once food enters the stomach; gastric acids and enzymes process the ingested materials
- gastrin** hormone which stimulates hydrochloric acid secretion in the stomach
- gastrovascular cavity** digestive system consisting of a single opening
- gizzard** muscular organ that grinds food
- herbivore** animal that consumes strictly plant diet
- ileum** last part of the small intestine; connects the small intestine to the large intestine; important for absorption of B-12
- ingestion** act of taking in food
- intestinal phase** third digestive phase; begins when chyme enters the small intestine triggering digestive secretions and

controlling the rate of gastric emptying

**jejunum** second part of the small intestine

**lactase** enzyme that breaks down lactose into glucose and galactose

**large intestine** digestive system organ that reabsorbs water from undigested material and processes waste matter

**lipase** enzyme that chemically breaks down lipids

**liver** organ that produces bile for digestion and processes vitamins and lipids

**maltase** enzyme that breaks down maltose into glucose

**mineral** inorganic, elemental molecule that carries out important roles in the body

**monogastric** digestive system that consists of a single-chambered stomach

**omnivore** animal that consumes both plants and animals

**pancreas** gland that secretes digestive juices

**pepsin** enzyme found in the stomach whose main role is protein digestion

**pepsinogen** inactive form of pepsin

**peristalsis** wave-like movements of muscle tissue

**proventriculus** glandular part of a bird's stomach

**rectum** area of the body where feces is stored until elimination

**roughage** component of food that is low in energy and high in fiber

**ruminant** animal with a stomach divided into four compartments

**salivary amylase** enzyme found in saliva, which converts carbohydrates to maltose

**secretin** hormone which stimulates sodium bicarbonate secretion in the small intestine

**small intestine** organ where digestion of protein, fats, and carbohydrates is completed

**somatostatin** hormone released to stop acid secretion when the stomach is empty

**sphincter** band of muscle that controls movement of materials throughout the digestive tract

**stomach** saclike organ containing acidic digestive juices

**sucrase** enzyme that breaks down sucrose into glucose and fructose

**trypsin** pancreatic protease that breaks down protein

**villi** folds on the inner surface of the small intestine whose role is to increase absorption area

**vitamin** organic substance necessary in small amounts to sustain life

## CHAPTER SUMMARY

### 25.1 Digestive Systems

Different animals have evolved different types of digestive systems specialized to meet their dietary needs. Humans and many other animals have monogastric digestive systems with a single-chambered stomach. Birds have evolved a digestive system that includes a gizzard where the food is crushed into smaller pieces. This compensates for their inability to masticate. Ruminants that consume large amounts of plant material have a multi-chambered stomach that digests

roughage. Pseudo-ruminants have similar digestive processes as ruminants but do not have the four-compartment stomach. Processing food involves ingestion (eating), digestion (mechanical and enzymatic breakdown of large molecules), absorption (cellular uptake of nutrients), and elimination (removal of undigested waste as feces).

Many organs work together to digest food and absorb nutrients. The mouth is the point of ingestion and the location where both mechanical and chemical breakdown of food begins. Saliva contains an enzyme called amylase that breaks down carbohydrates. The food bolus travels through the esophagus by peristaltic movements to the stomach. The stomach has an extremely acidic environment. An enzyme called pepsin digests protein in the stomach. Further digestion and absorption take place in the small intestine. The large intestine reabsorbs water from the undigested food and stores waste until elimination.

## 25.2 Nutrition and Energy Production

Animal diet should be balanced and meet the needs of the body. Carbohydrates, proteins, and fats are the primary components of food. Some essential nutrients are required for cellular function but cannot be produced by the animal body. These include vitamins, minerals, some fatty acids, and some amino acids. Food intake in more than necessary amounts is stored as glycogen in the liver and muscle cells, and in fat cells. Excess adipose storage can lead to obesity and serious health problems. ATP is the energy currency of the cell and is obtained from the metabolic pathways. Excess carbohydrates and energy are stored as glycogen in the body.

## 25.3 Digestive System Processes

Digestion begins with ingestion, where the food is taken in the mouth. Digestion and absorption take place in a series of steps with special enzymes playing important roles in digesting carbohydrates, proteins, and lipids. Elimination describes removal of undigested food contents and waste products from the body. While most absorption occurs in the small intestines, the large intestine is responsible for the final removal of water that remains after the absorptive process of the small intestines. The cells that line the large intestine absorb some vitamins as well as any leftover salts and water. The large intestine (colon) is also where feces is formed.

## 25.4 Digestive System Regulation

The brain and the endocrine system control digestive processes. The brain controls the responses of hunger and satiety. The endocrine system controls the release of hormones and enzymes required for digestion of food in the digestive tract.

## REVIEW QUESTIONS

1. When you eat an apple, it is first physically broken down into smaller fragments. What is the term for this process?
  - a. elimination
  - b. absorption
  - c. mastication
  - d. peristalsis
2. Which of the following statements is true?
  - a. The majority of water is reabsorbed by the small intestines.
  - b. Elimination is a process that occurs via diffusion.
  - c. Absorption is the process that chemically breaks down food.
  - d. The small intestines absorb nutrients.
3. Ruminants and pseudo-ruminants are both able to digest plant materials but have different mechanisms for doing so. Which of the following is a pseudo-ruminant?
  - a. cow
  - b. goat
  - c. crow
  - d. horse
4. Which of the following statements about animal digestion is true?
  - a. Roughage is digested very quickly.
  - b. Birds eat large quantities at one time.
  - c. Birds have a four-chambered stomach.
  - d. In pseudo-ruminants, roughage is digested in the cecum.
5. Chemical and mechanical digestion begins in the mouth, and food is prepared into a \_\_\_\_\_, which is then swallowed.
  - a. bolus
  - b. trachea
  - c. peristalsis
  - d. sphincter

**6.** Which of the following statements about digestion is true?

- a. Pepsin is converted to pepsinogen with the help of hydrochloric acid.
- b. Starch digestion begins in the mouth.
- c. Wave-like muscle movements called peristalsis move food from the stomach to the mouth.
- d. Amino acids are absorbed through the intestinal lining of the ileum.

**7.** Chyme is highly acidic. What is secreted by the pancreas to neutralize chyme?

- a. hydrochloric acid
- b. bicarbonate
- c. bile
- d. amylase

**8.** How does the liver assist in fat digestion?

- a. produces bicarbonate
- b. concentrates bile salts
- c. produces bile
- d. produces pepsin

**9.** When you eat food, it is vital that the nutrients be absorbed. How does absorption occur?

- a. Food is mechanically and chemically broken down into smaller molecules.
- b. Alternating waves of muscular contraction facilitate movement of food.
- c. Partially digested food flows into the small intestine and food regurgitation is prevented.
- d. Nutrients diffuse across the intestines.

**10.** Certain organs control the release of hormones that have vital roles in digestion. Which of the following controls hunger and satiety signals?

- a. thymus
- b. adrenal cortex
- c. thyroid
- d. hypothalamus

**11.** One cup of which of the following has the most calories?

- a. spaghetti with tomato sauce
- b. deep-fried zucchini
- c. mixed fruit
- d. scrambled eggs

**12.** Plant materials, such as fruits and vegetables, are difficult to digest because they are difficult to break down. How are humans able to obtain nutrients from fruits and vegetables?

- a. Humans produce cellulase, which breaks down cellulose.
- b. Intestinal flora have enzymes that break down some of the fiber.
- c. Bile is released from the gallbladder to break down fiber.
- d. In the stomach, pepsin is produced to break down plant material.

**13.** Which statement is not an example of how fat is beneficial?

- a. Fat helps absorb lipid-soluble vitamins.
- b. Fat helps produce lipid-soluble hormones.
- c. Fat has low energy density.
- d. Fat makes you feel full faster.

**14.** Certain molecules are required by but not produced by the body. Fat- and water-soluble \_\_\_\_\_ are organic molecules that cannot be produced by the body but are required for many enzymatic functions.

- a. minerals
- b. vitamins
- c. amino acids
- d. sugars

**15.** What is the result of insufficient amounts of the mineral iodine in the body?

- a. muscle weakness
- b. poor immune function
- c. mood disturbances
- d. goiters

**16.** Adenosine triphosphate, or ATP, is the source of energy for cells. ATP stores energy in \_\_\_\_\_ bonds.

- a. carbohydrate
- b. glycolysis
- c. glycogen
- d. phosphodiester

**17.** Which of the following statements about glycogen is true?

- a. When an individual is sedentary, glycogen is converted to glucose.
- b. The liver releases glycogen when blood sugar drops.
- c. ATP is produced by excess glycogen and glucose.
- d. During glycolysis, glycogen is converted to pyruvic acid.

**18.** What is produced from excess ATP and glucose?

- a. glycogen
  - b. pyruvate
  - c. peptides
  - d. essential nutrients
- 19.** Which of the following is not a reason why ATP is required by animals?
- a. ATP is needed to build organic molecules.
  - b. ATP provides energy for muscle contraction.
  - c. ATP assists in electrical signal transmission.
  - d. ATP is the body's fuel source.
- 20.** Different macromolecules have varying amounts of energy density. Which of the following is the least energy dense?
- a. protein
  - b. fat
  - c. fiber
  - d. carbohydrates
- 21.** Which of the following does not play a role in masticating food?
- a. teeth
  - b. pharynx
  - c. saliva
  - d. tongue
- 22.** Which of the following statements about the process of digestion is true?
- a. Organisms absorb large molecules through digestive cells.
  - b. The last step of digestion is absorption.
  - c. Food is only mechanically broken down in the mouth.
  - d. Food is prepared into a bolus before it is swallowed.
- 23.** Which of the following enzymes is involved in carbohydrate digestion?
- a. pancreatic amylase
  - b. elastase
  - c. trypsin
  - d. pepsin
- 24.** In protein digestion, what happens in the stomach?
- a. Aminopeptidase and dipeptidase break peptides into amino acids.
  - b. Pepsin breaks proteins into peptides.
  - c. Trypsin, elastase, and chymotrypsin break proteins into peptides.
  - d. Carboxypeptidase breaks peptides into amino acids and peptides.
- 25.** Water reabsorption is an essential component of processing food. Where is the majority of water reabsorbed?
- a. small intestines
  - b. rectum
  - c. colon
  - d. anus
- 26.** If you come down with the flu, you might experience emesis. What causes emesis?
- a. stomach muscle contractions
  - b. neural signals that urge elimination
  - c. inadequate water reabsorption
  - d. excess water reabsorption
- 27.** Not all organs involved in processing food are involved in digestion. Which of the following organs is not involved in digestion?
- a. mouth
  - b. anus
  - c. stomach
  - d. small intestine
- 28.** Which of the following statements about digestion of food in the large intestines is true?
- a. Mechanical digestion occurs by bacteria.
  - b. Semi-solid waste is moved by wave-like muscle contractions.
  - c. Most nutrients are absorbed.
  - d. Peristaltic mixing occurs.
- 29.** Taking in food, or \_\_\_\_\_, is the first step of gaining nutrients from food.
- a. digestion
  - b. ingestion
  - c. elimination
  - d. absorption
- 30.** What is the correct order of processes by which nutrients and energy are obtained from food?

- a. digestion → ingestion → absorption → elimination
- b. ingestion → absorption → digestion → elimination
- c. ingestion → digestion → absorption → elimination
- d. ingestion → digestion → elimination → absorption

31. Gastric control has three phases that assist in digesting food. Which phase is initiated by chyme?

- a. intestinal
- b. gastric
- c. cephalic
- d. digestive

32. Which of the following occurs during the cephalic phase of gastric control?

- a. Salivation is triggered.
- b. Food is processed by gastric acids and enzymes.
- c. Gastrin is produced.
- d. Digestive secretions are released.

## CRITICAL THINKING QUESTIONS

36. Explain how villi and microvilli aid in absorption.

- a. Villi and microvilli increase the surface area of the small intestines, which aids in the absorption of bile salts and vitamin B12.
- b. Villi and microvilli increase the surface area of the small intestine, which increases the absorption of nutrients by diffusion.
- c. Villi and microvilli form the inner layer of epithelial tissue in the small intestine and increase the absorption of nutrients from chyme.
- d. Villi and microvilli absorb food through the small intestine via smooth muscle contractions called peristalsis.

37. Ruminants, such as this goat, are able to digest large amounts of plant material. How is plant material passed through, digested, and absorbed in the ruminant digestive system?

33. Hormones are essential for digesting ingested food items. Which hormone controls the release of bile from the gallbladder?

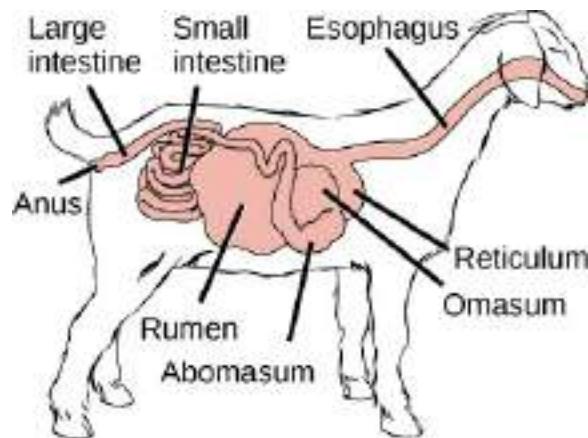

- a. pepsin
- b. gastrin
- c. amylase
- d. cholecystokinin

34. What is the role of gastrin in food digestion and absorption?

- a. Gastrin stimulates release of stomach acid.
- b. Gastrin stimulates production of bicarbonate.
- c. Gastrin stimulates pancreatic juice production.
- d. Gastrin stops the release of stomach acid.

35. The gastric phase assists in processing ingested materials. When does the gastric phase begin?

- a. when food is smelled
- b. when food reaches the stomach
- c. when chyme enters the small intestines
- d. when food is ingested

- a. Food is chewed in the mouth, then passes through the esophagus into the rumen and then the reticulum, which contain microbes that break down cellulose and ferment the ingested plant material. The ruminant regurgitates cud from the rumen, and the food is passed into the omasum for water removal and then into the small and large intestines for nutrient and further water absorption. Waste is excreted through the anus.
- b. Food is chewed in the mouth, then passes through the esophagus into the rumen and then the reticulum, which contain microbes that break down cellulose and ferment the ingested plant material. The ruminant regurgitates cud from the rumen, and the food is passed into the abomasum for water removal and then into the small and large intestines for nutrient and further water absorption. Waste is excreted through the anus.
- c. Food is chewed in the mouth, then passes through the esophagus into the rumen and then the reticulum, which contain microbes that break down proteins and ferment the ingested plant material. Ruminants regurgitate cud from the rumen, and the food is passed into the omasum for water removal and then into the small and large intestines for nutrient and further water absorption. Waste is excreted through the anus.
- d. Food is chewed in the mouth then passes through the esophagus into the reticulum and then the rumen, which contain microbes that break down cellulose and ferment the ingested plant material. The ruminant regurgitates cud from the rumen, and the food is passed into the omasum for water removal and then into the small and large intestines for nutrient and further water absorption. Waste is excreted through the anus.

**38. a. How does a stomach ulcer form?**

**b. How could you prevent a stomach ulcer from forming in your stomach?**

- a. When the serosa layer of stomach ruptures and does not reform, an open wound is formed. It may be caused by bacteria
- b. Ulcers can be prevented by eliminating ingesting items that cause degradation of the mucus lining like foods that irritate the stomach.
- a. When the mucus lining of the stomach ruptures and does not reform, an open wound is formed. It may be caused by a virus.
- b. Ulcers can be prevented by eliminating ingesting items that cause degradation of the mucus lining, like foods that irritate the stomach.
- a. When the mucus lining of the stomach ruptures and does not reform, an open wound is formed. It may be caused by bacteria.
- b. Ulcers can be prevented by ingesting items that will increase the acid content of the stomach.
- a. When the mucus lining of the stomach ruptures and does not reform, an open wound forms. It may be caused by bacteria.
- b. Ulcers can be prevented by eliminating ingesting items that cause degradation of the mucus lining, such as foods that irritate the stomach.

**39. How is the gallbladder involved in digestion, even though it is considered an accessory organ?**

- The gallbladder secretes bile to the duodenum, which uses it to break down proteins. It is considered an accessory organ because food does not directly pass through it.
- The gallbladder secretes bile to the duodenum, which uses it to break down fats. It is considered an accessory organ because food does not directly pass through it.
- The gallbladder secretes bile to the ileum, which uses it to break down fats. It is considered an accessory organ because food does not directly pass through it.
- The gallbladder secretes bile to the ileum, which uses it to break down proteins. It is considered an accessory organ because only a very small amount of digestion takes place in the gallbladder.

**40. What is the role of saliva in the digestive system?**

- a. Saliva contains an enzyme called amylase, which starts the chemical digestion in the mouth by breaking down proteins.
- b. Saliva contains an enzyme called lipase, which starts chemical digestion in the mouth by breaking down proteins.
- c. Saliva contains an enzyme called maltase, which starts chemical digestion in the mouth by breaking down carbohydrates.
- d. Saliva contains an enzyme called amylase, which starts chemical digestion in the mouth by breaking down carbohydrates.

**41.** What are the biological benefits of a balanced diet?

- a. A balanced diet provides excess energy to be stored in the body and nutrients to maintain good health and increase reproductive capability.
- b. A balanced diet allows excess energy to be stored in the body, thereby increasing the rate of metabolic reactions.
- c. A balanced diet provides nutrients needed to maintain proper bodily functions, and vitamins and minerals to maintain good health and reproductive capability.
- d. A balanced diet provides nutrients needed to maintain proper bodily functions, and vitamins and minerals to maintain good health and increase reproductive capability.

**42.** Why is it important to eat carbohydrates, which provide organic carbons?

- a. They are needed to provide insulation to mammals.
- b. They help to fight infections.
- c. They are needed to produce antibodies.
- d. They are needed to build cells and tissues.

**43.** a. Why is it necessary to consume essential nutrients?  
b. What are two examples of fat-soluble essential vitamins, and what are their functions in the human body?

- a. Essential nutrients are not synthesized by the body and are not necessary for proper body function.
- b. Vitamins B and C are two fat-soluble essential vitamins. Vitamin B helps maintain eyesight, and vitamin C is essential for blood clotting.
- b. Essential nutrients are not synthesized by the body but are necessary for proper body function.
- b. Vitamins A and K are two fat-soluble essential vitamins. Vitamin A helps maintain connective tissue, and vitamin K is essential for blood clotting.
- c. Essential nutrients are synthesized by the body and are necessary for proper body function.
- b. Vitamins D and K are two fat-soluble essential vitamins. Vitamin D helps maintain a stable nervous system, and vitamin K is essential for blood clotting.
- d. Essential nutrients are not synthesized by the body but are necessary for proper body function.
- b. Vitamins A and K are two fat-soluble essential vitamins. Vitamin A helps maintain eyesight, and vitamin K is essential for blood clotting.

**44.** What happens to glycogen when blood sugar drops?

- a. It stimulates the release of insulin, which can regulate the blood sugar level.
- b. It is released from the liver and converted to glucose to increase blood sugar levels.
- c. It is converted to starch, which breaks down to form glucose and increase blood sugar levels.
- d. It is released from the liver and converted to pyruvate, which can then form glucose to increase blood sugar levels.

**45.** What is the evolutionary significance of glycogen production?

- a. Excess ATP and glucose produce glycogen, which can be used at a later point in time to act as co-factor if, for example, a good source is scarce.
- b. Excess proteins and glucose produce glycogen, which can be used at a later point in time to produce energy if, for example, food is scarce.
- c. Excess ATP and glucose produce glycogen, which can be used at a later point in time to produce energy if, for example, food is scarce.
- d. Excess proteins and fats produce glycogen, which can be used at a later point in time to act as source of nitrogen if, for example, a good source is scarce.

**46.** How can eating too much bread and pasta physiologically promote obesity?

- a. Excess blood glucose increases the amount of urea, which is converted into fatty acids. Fatty acids are stored in areolar cells, which increase the amount of body fat.
- b. Excess blood glucose increases the amount of pyruvate, which is converted into fatty acids. Fatty acids are stored in adipose cells, which increase the amount of body fat.
- c. Bread and pasta are rich in fats. Their digestion produces fatty acids and glycerol. Fatty acids are stored in adipose cells, which increase the amount of body fat.
- d. Bread and pasta are rich in fats. Their digestion produces fatty acids and glycerol. Fatty acids are stored in areolar cells, which increase the amount of body fat.

**47. How do ingestion and digestion differ?**

- a. Ingestion is taking food in through mouth, where mechanical digestion begins. Chemical digestion begins in the stomach, where food is further broken down into smaller molecules that can be absorbed and used by the body.
- b. Ingestion is the process of taking in food through the mouth, where mechanical and chemical digestion begins to break down the food into smaller molecules that can be absorbed and used by the body.
- c. Ingestion is taking food in through the mouth, where mechanical and chemical digestion begins. Digestion in the stomach breaks down proteins and fats present in food into smaller molecules that can be absorbed and used by the body.
- d. Ingestion is the transfer of food from the mouth to the esophagus, where mechanical and chemical digestion begin to break down the food into smaller molecules that can be absorbed and used by the body.

**48. Why are some dietary lipids a necessary part of a balanced diet?**

- a. Dietary lipids aid in the absorption of water-soluble vitamins, including B and C, which are needed for various bodily functions.
- b. Dietary lipids aid in the absorption of some minerals, including folic acid, iron, and magnesium, which are needed for various bodily functions.
- c. Dietary lipids aid in the absorption of vitamins, including A, B, C, D, E, and K, which are needed for various bodily functions.
- d. Dietary lipids aid in the absorption of fat-soluble vitamins, including A, D, E, and K, which are needed for various bodily functions.

**49. What happens to undigested food after the water is reabsorbed?**

- a. Undigested food is moved through the colon, where intestinal flora aid in digestion by peristalsis, and then stored in the rectum until elimination through the anus.
- b. Undigested food is moved through the colon, where intestinal flora aid in digestion by peristalsis; further absorption takes place in the rectum, after which it stores the food until elimination through the anus.
- c. Undigested food is moved through the colon, where intestinal flora aid in digestion by segmentation, and then it is stored in the rectum until elimination through the anus.
- d. Undigested food is moved through the ileum, where intestinal flora aid in digestion by peristalsis, and then it is stored in the rectum until elimination through the anus.

**50. a. What are micelles?**

**b. Why are micelles integral to lipid absorption?**

- a. a. Micelles are lipoproteins designed for the transport of lipids that enter lacteals.  
b. Micelles facilitate absorption by microvilli, where the fatty acids and proteins diffuse out to form lipoproteins.
- b. a. Micelles are lipoproteins designed for the transport of lipids that enter lacteals.  
b. Micelles facilitate absorption by microvilli, where the fatty acids and monoglycerides diffuse out to form triglycerides.
- c. a. Micelles are bile salt-surrounded fatty acids and phospholipids.  
b. Micelles facilitate absorption by microvilli, where the fatty acids and monoglycerides diffuse out to form triglycerides.
- d. a. Micelles are bile salt-surrounded fatty acids and monoglycerides.  
b. Micelles facilitate absorption by microvilli, where the fatty acids and monoglycerides diffuse out to form triglycerides.

**51. On a cellular level, why must food be broken down?**

- a. Large molecules present in intact food pass through the digestive epithelium and enter the cell through the membrane, thereby damaging the nuclear membrane. Hence it must be broken down.
- b. Fats present in intact food contain very large molecules, which cannot pass through cell membranes. Fats need to be passed through the digestive epithelium to be utilized.
- c. Large molecules present in intact food cannot pass through cell membranes. Nutrients need to be passed through the digestive epithelium to be utilized.
- d. Large molecules, if not broken down, produce toxic substances that pass through the epithelium of the digestive tract and are utilized by the cells. This can be lethal to the cell.

52. What is the importance of neural responses to food stimuli?

- a. Neural responses facilitate secretion of fumarase needed for chemical digestion of food as well as other involuntary responses like peristalsis.
- b. Neural responses facilitate secretion of enzymes that are needed to digest or break down food as well as other involuntary responses like segmentation in stomach.
- c. Neural responses facilitate secretion of enzymes needed to digest or break down food as well as other involuntary responses like peristalsis.
- d. Neural responses facilitate secretion of salivary amylase needed to digest or break down food as well as secretion of hormones like secretin and gastrin.

## TEST PREP FOR AP® COURSES

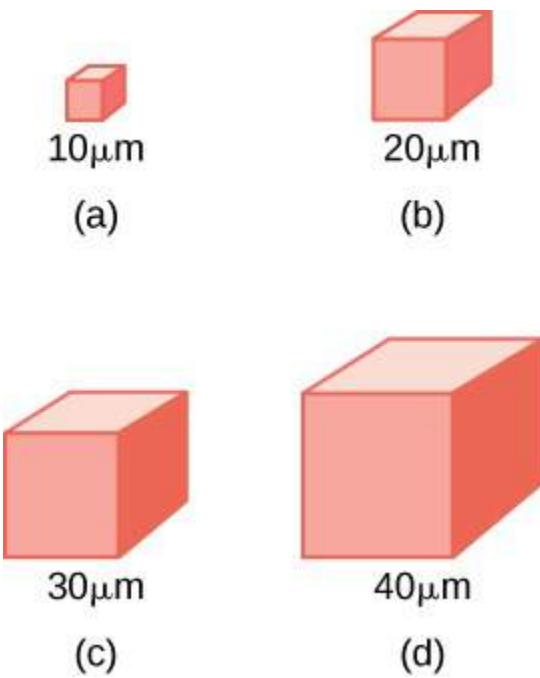

55. Simple cuboidal epithelial cells line the ducts of certain human exocrine glands. Various materials are transported into or out of the cells by diffusion. (The formula for the surface area of a cube is  $6 \times S^2$ , and the formula for the volume of a cube is  $S^3$ , where  $S$  = the length of a side of a cube.) Which of the following cube-shaped cells would be most efficient in removing waste by diffusion?

53. How do hormones regulate digestion?

- a. Hormones regulate aspects of digestion such as increasing the peristaltic movements in the esophagus when food is sensed.
- b. Hormones regulate digestion by signaling when the stomach is full or empty so that an individual will consume food or stop eating.
- c. Hormones like gastrin, secretin, adrenocorticotrophic are released from the pituitary to regulate which digestive secretions are released.
- d. Hormones regulate aspects of digestion such as which digestive secretions are released as well as when they are released.

54. When you are eating a meal, how do you know when you are full?

- a. The pituitary gland release hormones when the stomach is full, which therefore reduces hunger.
- b. The brain signals when the stomach is full that you are sated, which therefore reduces hunger.
- c. The stomach signals when it is full, which therefore reduces hunger.
- d. Low blood sugar levels stimulate a neurotransmitter, which sends a signal to the brain when the stomach is full and therefore reduces hunger.

- a. 10  $\mu\text{m}$
- b. 20  $\mu\text{m}$
- c. 30  $\mu\text{m}$
- d. 40  $\mu\text{m}$

**56.** Celiac disease is dangerous in affected individuals, because ingesting gluten damages the villi of the small intestines. Why is this potentially life threatening?

- a. The villi aid in mechanical digestion of food particles. When they are damaged, nutrients cannot be digested properly in the body.
- b. Villi increase the surface area of the small intestine, which aids in the absorption of bile salts. This nutrient cannot be absorbed when they are damaged.
- c. Villi decrease the surface area of the small intestine available for absorption. Nutrients cannot properly enter the bloodstream when they are damaged.
- d. Villi increase the surface area available for nutrient absorption. When villi are damaged, nutrients cannot properly enter the bloodstream.

**57.** One of the key features of villi and microvilli in the digestive system is their finger-like projection shape. Which of the following is an example of how the shape of microvilli can enhance nutrient absorption?

- a. Nutrients can enter the bloodstream through the blood vessels that are located in middle of the microvilli.
- b. Larger microvilli have more surface area over which more nutrients are absorbed.
- c. The microvilli projections aid in mechanical digestion of food particles.
- d. The finger-like projections prevent large particles of food from passing through the digestive system.

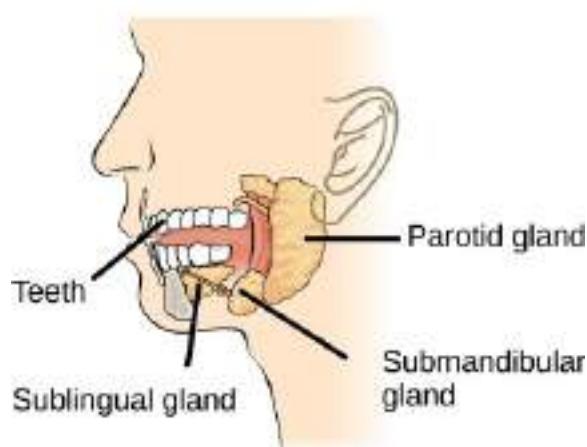

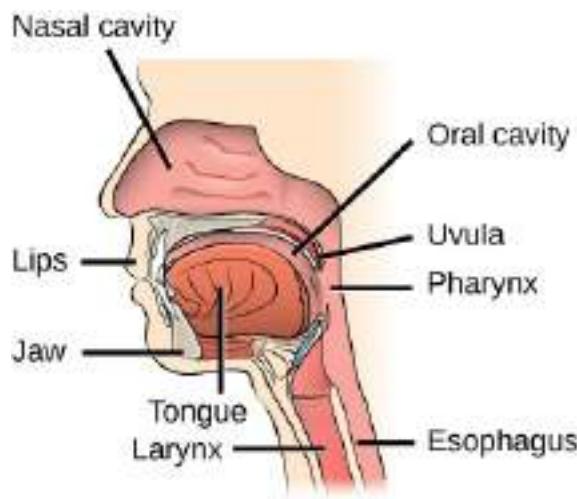

**58.** Microvilli greatly increase the efficiency of nutrient uptake in the small intestines. How do the size and shape of microvilli promote this efficiency?

- a. They have a greater surface area-to-volume ratio than larger cells. The finger-like projection shape provides more surface area over the small intestines from which they absorb nutrients and contains blood vessels so nutrients passing through them can enter the bloodstream readily.
- b. They have a greater surface area-to-volume ratio than larger cells. The finger-like projection shape is present in the middle of microvilli, which have more surface area over the small intestines from which they absorb nutrients and also contains blood vessels so nutrients can enter the blood easily.
- c. They have a greater surface area-to-volume ratio than larger cells. The finger-like projections prevent large particles of food from passing through the digestive system and also contain blood vessels so nutrients passed through them can readily enter the bloodstream.
- d. They have a greater surface area-to-volume ratio than larger cells. The finger-like projections aid in mechanical digestion of food particles and contain blood vessels so nutrients passing through them can enter the bloodstream readily.

**59.** Birds have several unique physical differences from other vertebrates, and several pertain to how birds process food. Some differences are obvious, such as the presence of a beak and no teeth, whereas other differences can be observed in their internal features. For example, birds have a monogastric digestive system like most other vertebrates, but their digestive system structure differs from that of most other monogastric vertebrates. Which of the following is true about how birds process food?

- a. Beak emergence coincided with insect inclusion in the bird diet.
- b. The gizzard is the primary site of mechanical digestion.
- c. Birds excrete nitrogenous waste and feces through separate openings.
- d. Birds digest plant material more slowly than ruminants.

**60.** As shown in this figure, the oral cavity has several components that contribute to ingestion and the initial stages of digestion. How do the components of the oral cavity work together to complete the first step of food processing?

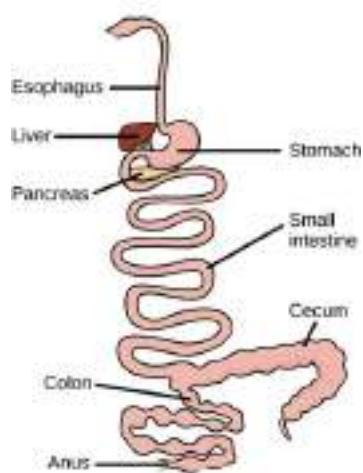

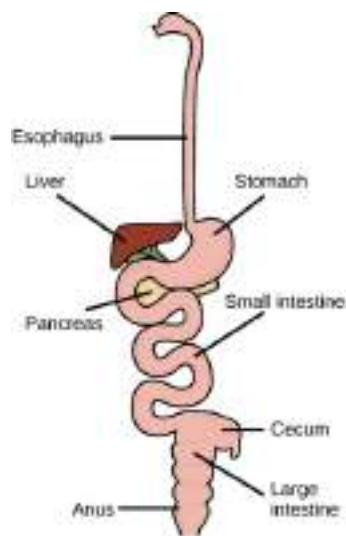

- a. The teeth and jaw mechanically chew the food, and saliva from the salivary glands moistens the food and begins chemical digestion. The tongue then physically moves the food to the pharynx, where peristalsis moves the food into the stomach.
- b. The teeth and jaw mechanically chew the food, and saliva from the salivary glands moistens the food and initiates mechanical and chemical digestion. The tongue then physically moves the food to the pharynx, where peristalsis moves the food into the stomach.
- c. The teeth and jaw mechanically chew the food, and saliva from the salivary glands moistens the food and begins chemical digestion. The tongue then physically moves the food to the larynx, where peristalsis moves the food into the stomach.
- d. The teeth and jaw mechanically chew the food, and saliva from the salivary glands moistens the food and initiates mechanical and chemical digestion. The tongue then physically moves the food to the pharynx, where segmentation moves the food into the stomach.

**61.** Most mammals have a monogastric digestive system, which means they have one stomach chamber. Ruminants and pseudo-ruminants consume a large amount of plant material and have polygastric digestive systems, which means they have more than one stomach chamber. Why is an increased number of stomach chambers beneficial for ruminants and pseudo-ruminants?

- a. Microbes in the chambers break down and ferment plant material.
- b. Extended exposure to stomach acid breaks down more cellulose.
- c. Increased amounts of peristalsis crush more of the plant fibers.
- d. Having more stomach chambers increases exposure for nutrients to be absorbed.

**62.** This figure shows the majority of the digestive tracts of two organisms that consume different food sources. a. Which digestive tract belongs to the herbivore? b. How did you determine this?

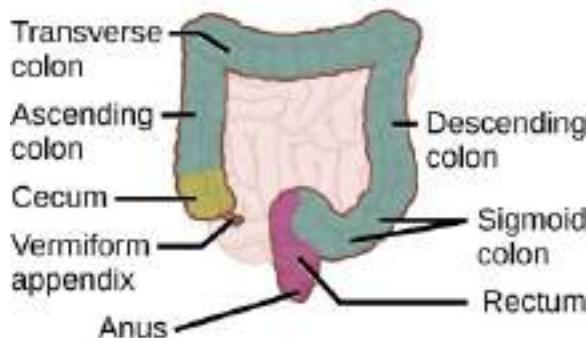

- a. a. The digestive tract shown at the bottom belongs to the herbivore. b. Herbivores have a shorter intestinal tract, which allows stronger smooth muscle contractions called peristalsis in a shorter area, providing more opportunity for nutrients to be obtained and absorbed.
- b. a. The digestive tract shown at the top belongs to the herbivore. b. Herbivores have a longer intestinal tract, which provides more opportunity for nutrients to be obtained and absorbed, since plant material is difficult for animals to break down.
- c. a. The digestive tract shown at the bottom belongs to the herbivore. b. Herbivores have a longer intestinal tract, which provides more opportunity for the nutrients to react with the intestinal enzymes for better absorption, since plant material is difficult for animals to break down.
- d. a. The digestive tract shown at the bottom belongs to the herbivore. b. Herbivores have a shorter intestinal tract, which provides more opportunity for nutrients to be obtained and absorbed, since plant material is difficult for animals to break down.

**63.** The ruminant digestive system has evolved several differences from the traditional mammalian monogastric digestive system because they consume large amounts of plant material. Which of the following is NOT a component of the ruminant digestive system that has evolved to more efficiently digest plant fibers?

- a. omasum
- b. abomasum
- c. reticulum
- d. gizzard

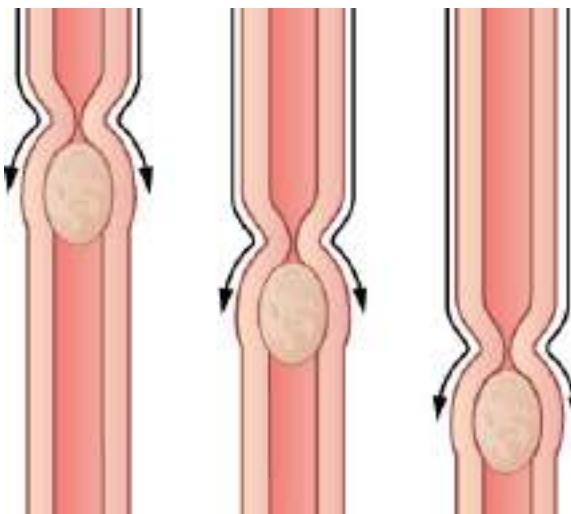

**64.**

This figure shows the three main components of the large intestine. How do these three parts contribute to processing as food material passes through the large intestine?

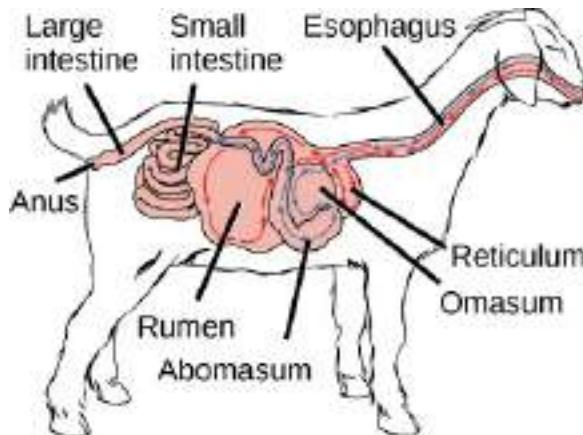

- a. The cecum receives semi-solid waste from the small intestine and absorbs water, vitamins, and minerals. Then the colon further digests some material. The rectum stores the fecal matter until it is excreted.
- b. The cecum receives semi-solid waste from the small intestine. Then the colon digests some materials. The rectum absorbs water and some vitamins and minerals and then stores the fecal matter until it is excreted.
- c. The cecum receives semi-solid waste from small intestine. Then, the colon absorbs water and some vitamins and minerals, and further digests some material. The rectum stores the fecal matter until it is excreted.
- d. The cecum receives semi-solid waste from the small intestine. The colon is the only region where absorption of vitamins takes place in the digestive system. The rectum stores the fecal matter until it is excreted.

**65.** This figure shows involuntary muscle movement in part of the digestive system. What stimulates this involuntary response?

- a. smelling food
- b. seeing food
- c. chewing food
- d. swallowing food

**66.** This image shows the digestive system of a ruminant animal. How does this polygastric digestive system enhance digestion efficiency in ruminants?

- a. Multiple stomach chambers in ruminant animals contain microbes that have cellulase, which breaks down plant material. Plant material is difficult to digest because animals lack cellulase to break down cellulose.
- b. Multiple stomach chambers in ruminant animals allow stronger smooth muscle contractions, which break down plant material. Plant material is difficult to digest because animals lack cellulase to break down cellulose.
- c. Multiple stomach chambers present in ruminant animals contain cellulase, which break down plant material. Plant material is difficult to digest because animals lack cellulase to break down cellulose.
- d. Multiple stomach chambers in ruminant animals allow the food to stay in the stomach for a longer time so that peristaltic movements and the action of enzymes on food particles occurs for a longer time.

**67.**

An experiment to measure the rate of respiration in mice at 10°C and 25°C was performed using a respirometer, an apparatus that measures changes in gas volume. Respiration was measured in mL of O<sub>2</sub> consumed per gram of organism over several five-minute trials, and the following data were obtained.

| Organism | Temperature (°C) | Average respiration (mL O <sub>2</sub> /g/min) |
|----------|------------------|------------------------------------------------|
| Mouse    | 10               | 0.0518                                         |
| Mouse    | 25               | 0.0321                                         |

According to these data, mice at 10°C demonstrated

greater oxygen consumption per gram of tissue than mice at 25°C. Which of the following statements best explains the observation?

- The mice at 10°C had a higher rate of ATP production than the mice at 25°C.
- The mice at 10°C had a lower metabolic rate than the mice at 25°C.
- The mice at 25°C weighed less than the mice at 10°C.
- The mice at 25°C were more active than the mice at 10°C.

**68.** ATP is essential for organisms because it provides energy to cells. How does ATP provide this energy on a physiological level?

- When energy is needed, ATP is converted to ADP and a phosphate group. Energy is released from the breaking of the phosphodiester bonds.
- When energy is needed, ATP is converted to ADP and a phosphate group. Energy is released from the breaking of the glycosidic bonds.
- When energy is needed, ATP is formed from ADP and a phosphate group. Energy is released from the breaking of the phosphodiester bonds.
- When energy is needed, ATP is formed from ADP and a phosphate group. Energy is released from the breaking of the phosphoanhydride bonds.

**69.** An omnivore comes across potatoes, avocados, kale, and eggs and craves only the eggs. In what nutrient is the animal likely deficient?

- carbohydrates
- protein
- fiber
- fatty acids

**70.** Carbohydrates often get a bad reputation for their role in promoting weight gain when consumed in excess. However, carbohydrates are necessary for biological functions. Why is it important to consume carbohydrates?

- Carbohydrates are broken down into glucose, which provides energy as ATP through metabolic pathways. ATP helps to maintain connective tissue.
- Carbohydrates are broken down into glucose, which is essential for blood clotting.
- Carbohydrates, along with proteins, help maintain connective tissue and are essential to blood clotting.
- Carbohydrates are broken down into glucose, which provides energy as ATP through metabolic pathways. ATP is required for proper cellular function.

**71.** Excess ATP is combined with excess glucose and stored as glycogen in the liver and skeletal muscle. Under what circumstance would glycogen storage in skeletal muscle prove beneficial for a rabbit?

- A rabbit has not eaten recently and its blood sugar drops.
- There is an overabundance of food available to a rabbit.
- A rabbit spots a coyote and flees in response.
- A young rabbit with an adequate food source is developing into an adult rabbit.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**72.** *E. coli* colonize the human gastrointestinal tract. The temperature of that environment is tightly regulated. However, the pH ranges from the highly acidic stomach (pH 4.5) to the relatively basic lower intestine (pH 9). Over the entire pH range of the environment the pH of the *E. coli* cytoplasm is maintained in a narrow range between 7.2 and 7.8. Wilks and Slonczewski (*Journal of Bacteriology*, 189, 2007) used a fluorescent dye to follow the recovery of cytoplasmic pH after an acid shock comparable to what occurs in the human stomach. They found that the pH within the cell recovered in approximately 2 minutes.

Rapid restoration of cytoplasmic pH does not occur in the presence of ATPase inhibitors. **Construct an explanation** for the mechanisms that maintain homeostasis with a model of exchange of hydrogen ions (H<sup>+</sup>) between the cell and its extracellular environment.

**73.** We need an explanation of the common experience that an "upset stomach" (functional dyspepsia) or constipation can result from stress. Irritable bowel syndrome is a chronic gastrointestinal disease and is treated with the neurotransmitter serotonin. Serotonin receptors are located on the cell membranes of neurons and activate second messenger cascades that regulate gene expression. In humans most serotonin is synthesized in neurons that enervate smooth muscle cells lining the gastrointestinal tract. There is an association of serotonin with a sense of well-being.

A. Based on these data, **justify the claim** that timing of the passage of food in the gastrointestinal tract is regulated by serotonin.

The effect of serotonin on smooth muscle is a clue but it doesn't provide a mechanism connecting stress to the symptoms of functional dyspepsia. Serotonin is

synthesized by all Bilateria (animals with bilateral symmetry, including humans) and is released as a response to stress (Puglisi-Allegra and Andolini, *Behavioral Brain Research*, 277, 2015). Serotonin is also synthesized by plants to regulate root growth.

B. **Describe** the role for serotonin that is indicated across domains.

C. **Evaluate** the effect that stress produces in serotonin production, the association of stress with functional dyspepsia, and the role of serotonin in the regulation of expression in smooth muscle cells in terms of evidence of a negative feedback produced by serotonin as a medication.

D. **Justify** your evaluation of the stress and the role of serotonin as a response to the stress in the form of a feedback loop diagrammatically.

Quorum sensing coordinates bacterial expression, stimulating virulence factors, and behavior, inducing the formation of biofilms. Knecht *et al.* (*EBioMedicine*, 9, 2016) have demonstrated that serotonin functions as a quorum sensing messenger among bacteria in the gastrointestinal tract of mice.

E. **Construct an explanation** of the effect of serotonin as a treatment of functional dyspepsia.

# 26 | THE NERVOUS SYSTEM

**Figure 26.1** An athlete's nervous system is hard at work during the planning and execution of a movement as precise as a high jump. Parts of the nervous system are involved in determining how hard to push off and when to turn, as well as controlling the muscles throughout the body that make this complicated movement possible without knocking the bar down—all in just a few seconds. (credit: modification of work by Shane T. McCoy, U.S. Navy)

## Chapter Outline

- 26.1: Neurons and Glial Cells**
- 26.2: How Neurons Communicate**
- 26.3: The Central Nervous System**
- 26.4: The Peripheral Nervous System**
- 26.5: Nervous System Disorders**

## Introduction

While you're reading this book, your nervous system is performing several functions simultaneously. The visual system is processing what is seen on the page, the motor system controls the turn of the pages (or click of the mouse), and the prefrontal cortex maintains attention. Even fundamental functions, like breathing and regulation of body temperature, are controlled by the nervous system. A nervous system is an organism's control center: it processes sensory information from outside (and inside) the body and controls all behaviors—from eating to sleeping to finding a mate.

Scientists have even discovered that certain individual neurons (a type of nerve cell) can multitask. Neuroscientists often use the model organism *C. elegans* (a worm) to study neurons. While studying these worms, it was recently discovered that one type of neuron called AIY regulates both speed and direction of movement. Even though humans have billions of neurons compared to the 302 in *C. elegans*, it is thought that many perform multiple functions.<sup>1</sup> You can read more about this research at the [Science Daily website \(<http://openstaxcollege.org/l/32neurons>\)](http://openstaxcollege.org/l/32neurons).

1. University of Michigan. First peek at how neurons multitask. *Science Daily*, 6 November 2014. [www.sciencedaily.com/releases/2014/11/141106131520.htm](http://www.sciencedaily.com/releases/2014/11/141106131520.htm).

## 26.1 | Neurons and Glial Cells

In this section, you will explore the following questions:

- What are the functions of the structural components of a neuron?
- What are the four main types of neurons?
- What are the functions of different types of glial cells?

### Connection for AP® Courses

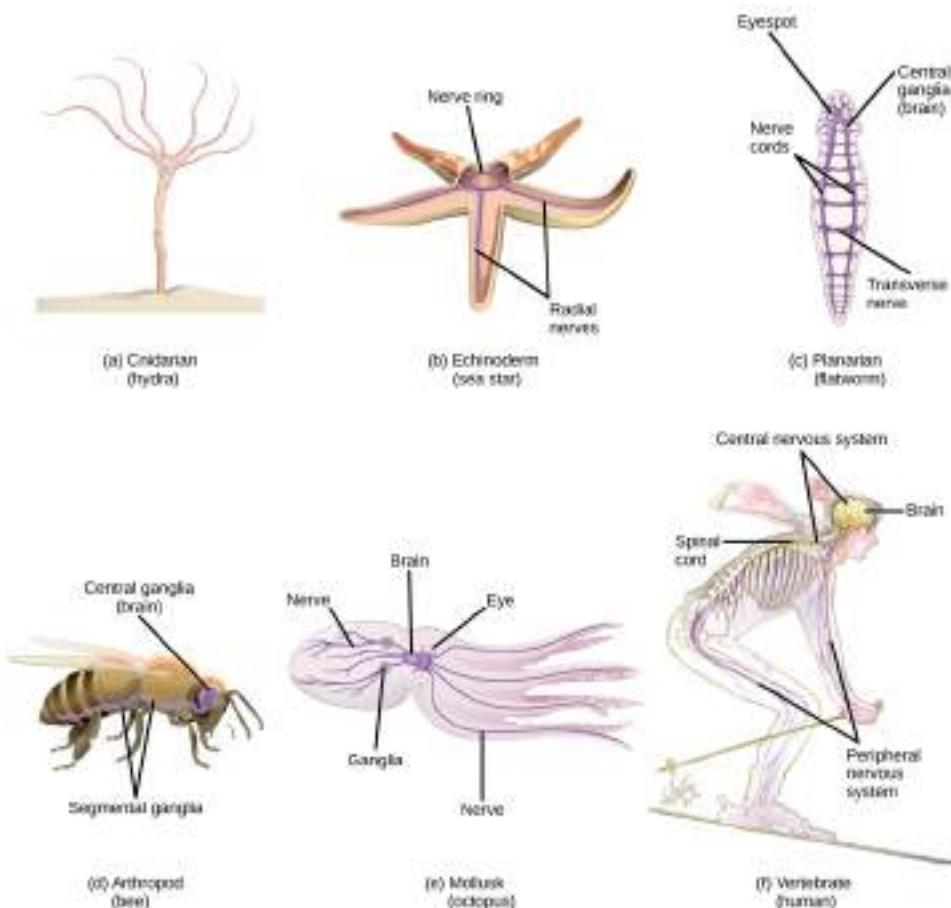

Much information about the various organ systems of animals is not within the scope of AP®. The nervous system, however, was selected for in-depth study because an animal's ability to detect, transmit, and respond to information is critical for survival. The nervous system interacts with all other organ systems to coordinate responses. The information in this chapter allows us to apply concepts we explored previously, including structure and function relationships, homeostasis, the movement of substances across cell membranes, cell signaling and communication, and the use of ATP.

Nervous systems in animals range from relatively simple nerve nets in jellyfish to a complex brain, spinal cord, and peripheral nervous in humans. (For the purpose of AP®, you do not need to have detailed information about myriad types of nervous systems in other animals. Instead, just focus on the complex nervous system of humans.) The basic structure of the nervous system that reflects function is the neuron, of which there are three types: sensory, motor, and interneuron. A typical neuron consists of **dendrites**, a cell body, and an **axon** to detect, generate, transmit, and integrate signal information. Many neurons are surrounded by **Schwann cells** (a type of glial cell) that form a **myelin** sheath, which acts as an electrical insulator, like the plastic wrap that surrounds the copper wires in a household appliance cord. The Schwann cells are separated by gaps of unmyelinated fibers called **nodes of Ranvier** over which the nerve impulse travels as the signal passes along the neuron, increasing the speed of transmission. (As we will learn in the **Nervous System Disorders** section, some diseases of the nervous system result from the loss of myelin.) Glial cells—often thought of as the “supporting cast” of the nervous system—outnumber neurons and play a role in the development of neurons, buffer harmful ions and chemicals, and provide myelin sheaths around neurons. Most brain tumors are caused by mutations in glial cells.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Nervous systems throughout the animal kingdom vary in structure and complexity, as illustrated by the variety of animals shown in **Figure 26.2**. Some organisms, like sea sponges, lack a true nervous system. Others, like jellyfish, lack a true brain and instead have a system of separate but connected nerve cells (neurons) called a “nerve net.” Echinoderms such as sea stars have nerve cells that are bundled into fibers called nerves. Flatworms of the phylum Platyhelminthes have both a central nervous system (CNS), made up of a small “brain” and two nerve cords, and a peripheral nervous system (PNS) containing a system of nerves that extend throughout the body. The insect nervous system is more complex but also fairly decentralized. It contains a brain, ventral nerve cord, and ganglia (clusters of connected neurons). These ganglia can control movements and behaviors without input from the brain. Octopi may have the most complicated of invertebrate nervous systems—they have neurons that are organized in specialized lobes and eyes that are structurally similar to vertebrate species.

**Figure 26.2** Nervous systems vary in structure and complexity. In (a) cnidarians, nerve cells form a decentralized nerve net. In (b) echinoderms, nerve cells are bundled into fibers called nerves. In animals exhibiting bilateral symmetry such as (c) planarians, neurons cluster into an anterior brain that processes information. In addition to a brain, (d) arthropods have clusters of nerve cell bodies, called peripheral ganglia, located along the ventral nerve cord. Mollusks such as squid and (e) octopi, which must hunt to survive, have complex brains containing millions of neurons. In (f) vertebrates, the brain and spinal cord comprise the central nervous system, while neurons extending into the rest of the body comprise the peripheral nervous system. (credit e: modification of work by Michael Vecchione, Clyde F.E. Roper, and Michael J. Sweeney, NOAA; credit f: modification of work by NIH)

Compared to invertebrates, vertebrate nervous systems are more complex, centralized, and specialized. While there is great diversity among different vertebrate nervous systems, they all share a basic structure: a CNS that contains a brain and spinal cord and a PNS made up of peripheral sensory and motor nerves. One interesting difference between the nervous systems of invertebrates and vertebrates is that the nerve cords of many invertebrates are located ventrally whereas the vertebrate spinal cords are located dorsally. There is debate among evolutionary biologists as to whether these different nervous system plans evolved separately or whether the invertebrate body plan arrangement somehow “flipped” during the evolution of vertebrates.

Watch [this video](http://openstaxcollege.org/l/vertebrate_evol) ([http://openstaxcollege.org/l/vertebrate\\_evol](http://openstaxcollege.org/l/vertebrate_evol)) of biologist Mark Kirschner discussing the “flipping” phenomenon of vertebrate evolution.

The nervous system is made up of **neurons**, specialized cells that can receive and transmit chemical or electrical signals, and **glia**, cells that provide support functions for the neurons by playing an information processing role that is complementary to neurons. A neuron can be compared to an electrical wire—it transmits a signal from one place to another. Glia can be compared to the workers at the electric company who make sure wires go to the right places, maintain the wires, and take down wires that are broken. Although glia have been compared to workers, recent evidence suggests that also usurp some of the signaling functions of neurons.

There is great diversity in the types of neurons and glia that are present in different parts of the nervous system. There are four major types of neurons, and they share several important cellular components.

## Neurons

The nervous system of the common laboratory fly, *Drosophila melanogaster*, contains around 100,000 neurons, the same number as a lobster. This number compares to 75 million in the mouse and 300 million in the octopus. A human brain contains around 86 billion neurons. Despite these very different numbers, the nervous systems of these animals control many of the same behaviors—from basic reflexes to more complicated behaviors like finding food and courting mates. The ability of neurons to communicate with each other as well as with other types of cells underlies all of these behaviors.

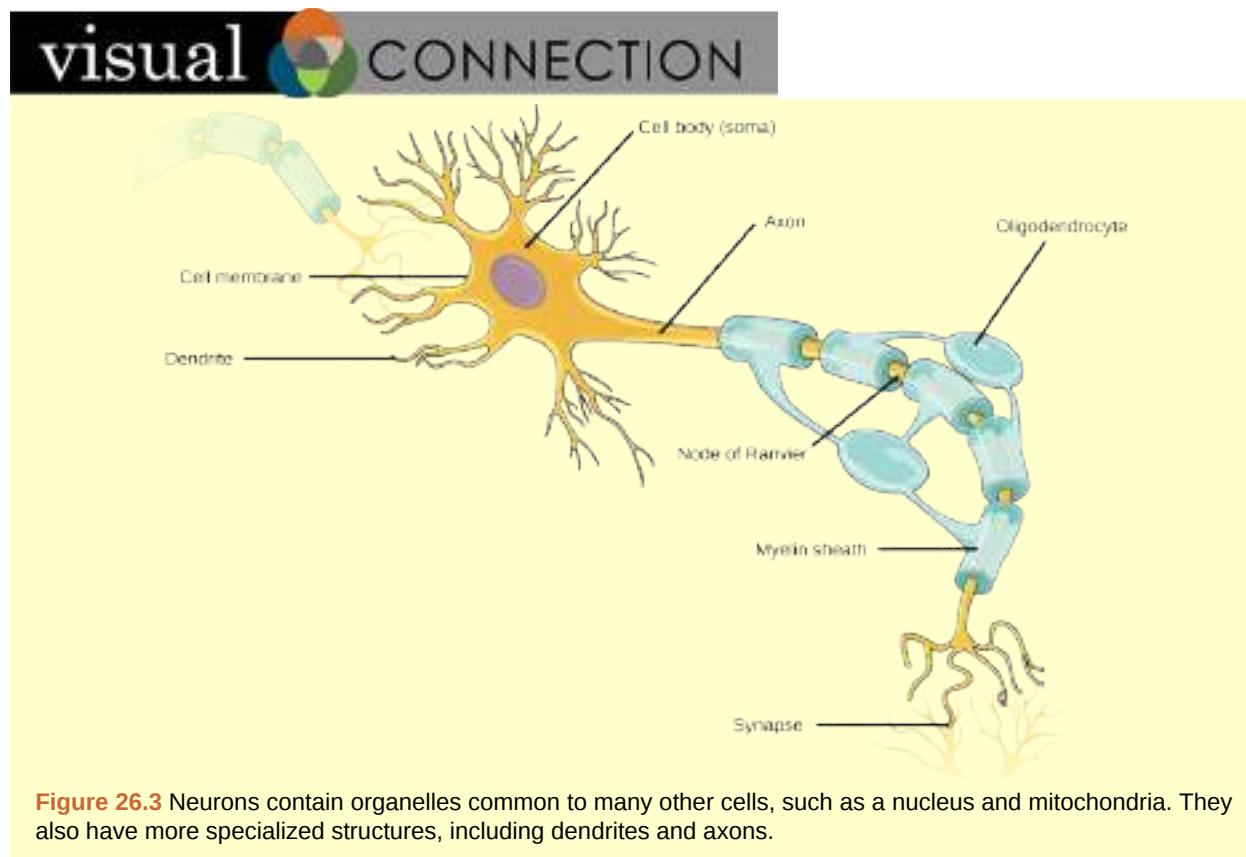

Most neurons share the same cellular components. But neurons are also highly specialized—different types of neurons have different sizes and shapes that relate to their functional roles.

### Parts of a Neuron

Like other cells, each neuron has a cell body (or soma) that contains a nucleus, smooth and rough endoplasmic reticulum, Golgi apparatus, mitochondria, and other cellular components. Neurons also contain unique structures, illustrated in [Figure 26.3](#) for receiving and sending the electrical signals that make neuronal communication possible. Dendrites are tree-like structures that extend away from the cell body to receive messages from other neurons at specialized junctions called **synapses**. Although some neurons do not have any dendrites, some types of neurons have multiple dendrites. Dendrites can have small protrusions called dendritic spines, which further increase surface area for possible synaptic connections.

Once a signal is received by the dendrite, it then travels passively to the cell body. The cell body contains a specialized structure, the **axon hillock** that integrates signals from multiple synapses and serves as a junction between the cell body and an axon. An axon is a tube-like structure that propagates the integrated signal to specialized endings called **axon terminals**. These terminals in turn synapse on other neurons, muscle, or target organs. Chemicals released at axon terminals allow signals to be communicated to these other cells. Neurons usually have one or two axons, but some neurons, like amacrine cells in the retina, do not contain any axons. Some axons are covered with myelin, which acts as an insulator to minimize dissipation of the electrical signal as it travels down the axon, greatly increasing the speed of conduction. This insulation is important as the axon from a human motor neuron can be as long as a meter—from the base of the spine to the toes. The myelin sheath is not actually part of the neuron. Myelin is produced by glial cells. Along the axon there are periodic gaps in the myelin sheath. These gaps are called nodes of Ranvier and are sites where the signal is “recharged” as it travels along the axon.

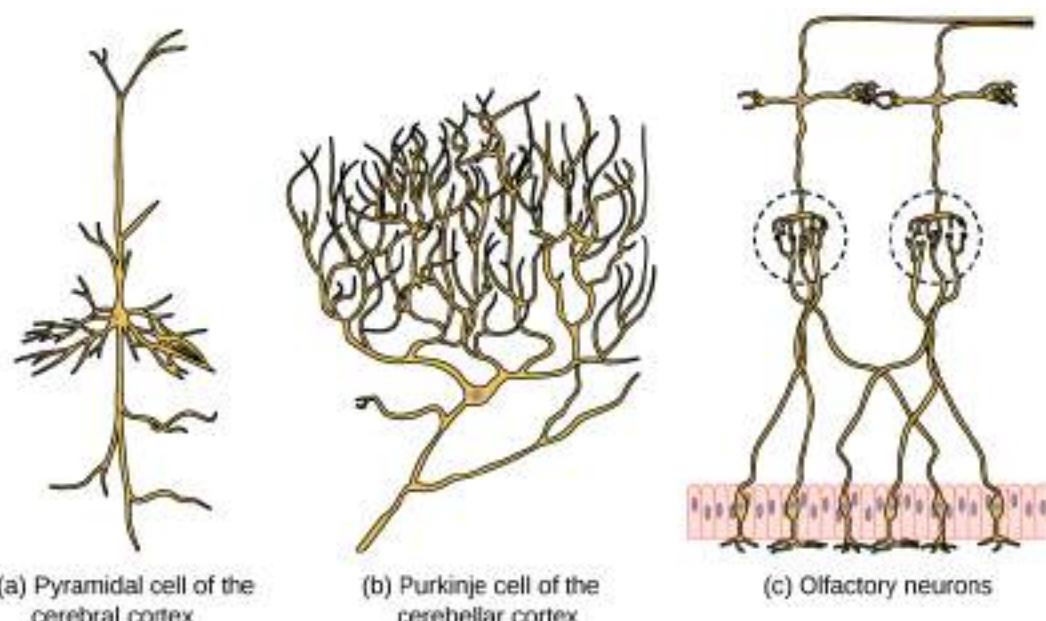

It is important to note that a single neuron does not act alone—neuronal communication depends on the connections that neurons make with one another (as well as with other cells, like muscle cells). Dendrites from a single neuron may receive synaptic contact from many other neurons. For example, dendrites from a Purkinje cell in the cerebellum are thought to receive contact from as many as 200,000 other neurons.

**Figure 26.3** Neurons contain organelles common to many other cells, such as a nucleus and mitochondria. They also have more specialized structures, including dendrites and axons.

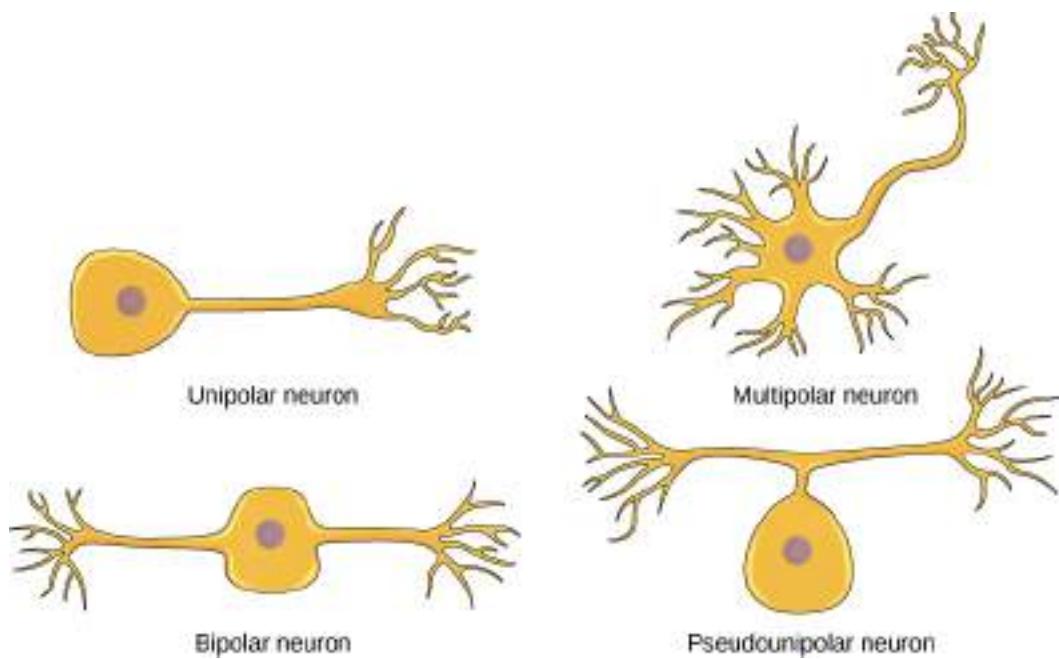

#### **Types of Neurons**

There are different types of neurons, and the functional role of a given neuron is intimately dependent on its structure. There is an amazing diversity of neuron shapes and sizes found in different parts of the nervous system (and across species), as illustrated by the neurons shown in **Figure 26.4**.

**Figure 26.4** There is great diversity in the size and shape of neurons throughout the nervous system. Examples include (a) a pyramidal cell from the cerebral cortex, (b) a Purkinje cell from the cerebellar cortex, and (c) olfactory cells from the olfactory epithelium and olfactory bulb.

While there are many defined neuron cell subtypes, neurons are broadly divided into four basic types: unipolar, bipolar, multipolar, and pseudounipolar. **Figure 26.5** illustrates these four basic neuron types. Unipolar neurons have only one structure that extends away from the soma. These neurons are not found in vertebrates but are found in insects where they stimulate muscles or glands. A bipolar neuron has one axon and one dendrite extending from the soma. An example of a bipolar neuron is a retinal bipolar cell, which receives signals from photoreceptor cells that are sensitive to light and transmits these signals to ganglion cells that carry the signal to the brain. Multipolar neurons are the most common type of neuron. Each multipolar neuron contains one axon and multiple dendrites. Multipolar neurons can be found in the central nervous system (brain and spinal cord). An example of a multipolar neuron is a Purkinje cell in the cerebellum, which has many branching dendrites but only one axon. Pseudounipolar cells share characteristics with both unipolar and bipolar cells. A pseudounipolar cell has a single process that extends from the soma, like a unipolar cell, but this process later branches into two distinct structures, like a bipolar cell. Most sensory neurons are pseudounipolar and have an axon that branches into two extensions: one connected to dendrites that receive sensory information and another that transmits this information to the spinal cord.

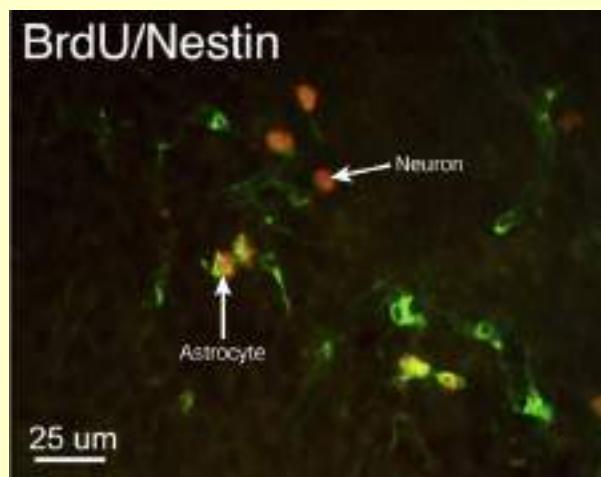

**Figure 26.5** Neurons are broadly divided into four main types based on the number and placement of axons: (1) unipolar, (2) bipolar, (3) multipolar, and (4) pseudounipolar.

# everyday CONNECTION

## Neurogenesis

At one time, scientists believed that people were born with all the neurons they would ever have. Research performed during the last few decades indicates that neurogenesis, the birth of new neurons, continues into adulthood. Neurogenesis was first discovered in songbirds that produce new neurons while learning songs. For mammals, new neurons also play an important role in learning: about 1000 new neurons develop in the hippocampus (a brain structure involved in learning and memory) each day. While most of the new neurons will die, researchers found that an increase in the number of surviving new neurons in the hippocampus correlated with how well rats learned a new task. Interestingly, exercise also promotes neurogenesis in the hippocampus. Stress has the opposite effect. While neurogenesis is quite limited compared to regeneration in other tissues, research in this area may lead to new treatments for disorders such as Alzheimer's, stroke, and epilepsy.

How do scientists identify new neurons? A researcher can inject a compound called bromodeoxyuridine (BrdU) into the brain of an animal. While all cells will be exposed to BrdU, BrdU will only be incorporated into the DNA of newly generated cells that are in S phase. A technique called immunohistochemistry can be used to attach a fluorescent label to the incorporated BrdU, and a researcher can use fluorescent microscopy to visualize the presence of BrdU, and thus new neurons, in brain tissue. **Figure 26.6** is a micrograph which shows fluorescently labeled neurons in the hippocampus of a rat.

**Figure 26.6** This micrograph shows fluorescently labeled new neurons in a rat hippocampus. Cells that are actively dividing have bromodeoxyuridine (BrdU) incorporated into their DNA and are labeled in red. Cells that express glial fibrillary acidic protein (GFAP) are labeled in green. Astrocytes, but not neurons, express GFAP. Thus, cells that are labeled both red and green are actively dividing astrocytes, whereas cells labeled red only are actively dividing neurons. (credit: modification of work by Dr. Maryam Faiz, et. al., University of Barcelona; scale-bar data from Matt Russell)

This site (<http://openstaxcollege.org/l/neurogenesis>) contains more information about neurogenesis, including an interactive laboratory simulation and a video that explains how BrdU labels new cells.

# science practices CONNECTION for AP<sup>®</sup> Courses

## Think About It

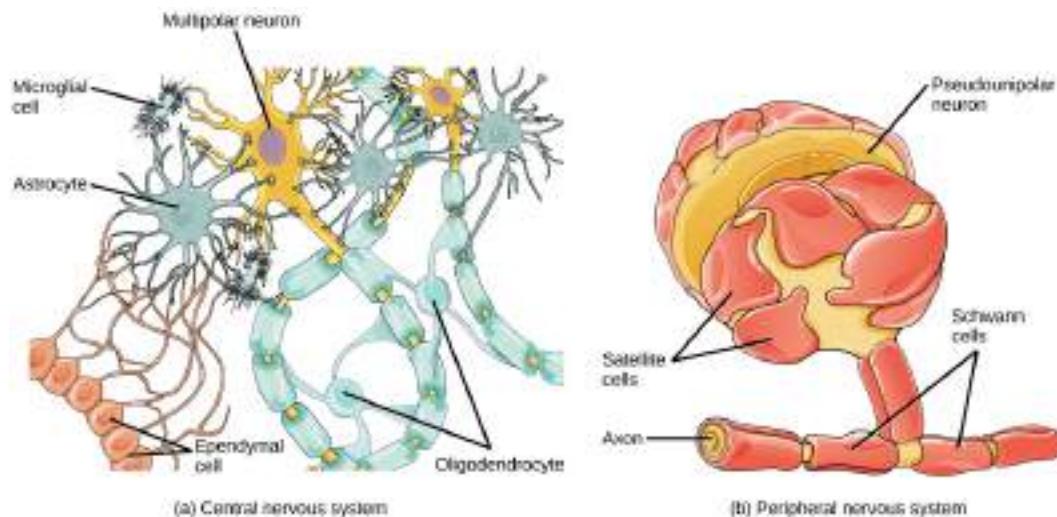

How does the unique structure of the neuron allow it to detect (and ultimately transmit) incoming signals?

## Glia

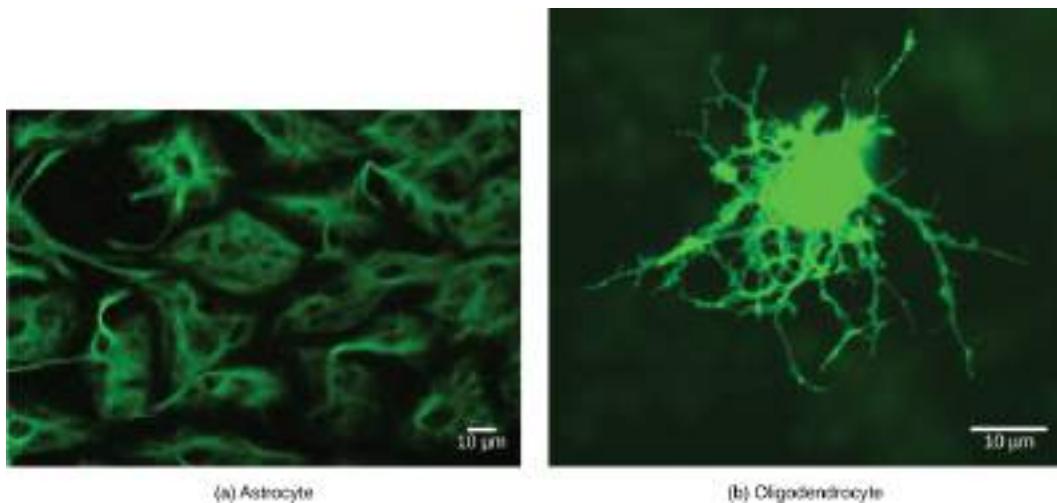

While glia are often thought of as the supporting cast of the nervous system, the number of glial cells in the brain actually outnumbers the number of neurons by a factor of ten. Neurons would be unable to function without the vital roles that are fulfilled by these glial cells. Glia guide developing neurons to their destinations, buffer ions and chemicals that would otherwise harm neurons, and provide myelin sheaths around axons. Scientists have recently discovered that they also play a role in responding to nerve activity and modulating communication between nerve cells.

### Types of Glia

There are several different types of glia with different functions, two of which are shown in **Figure 26.7**. **Astrocytes**, shown in **Figure 26.8a** make contact with both capillaries and neurons in the CNS. They provide nutrients and other substances to neurons, regulate the concentrations of ions and chemicals in the extracellular fluid, and provide structural support for synapses. Astrocytes also form the blood-brain barrier—a structure that blocks entrance of toxic substances into the brain. Astrocytes, in particular, have been shown through calcium imaging experiments to become active in response to nerve activity, transmit calcium waves between astrocytes, and modulate the activity of surrounding synapses. **Satellite glia** provide nutrients and structural support for neurons in the PNS. **Microglia** scavenge and degrade dead cells and protect the brain from invading microorganisms. **Oligodendrocytes**, shown in **Figure 26.8b** form myelin sheaths around axons in the CNS. One axon can be myelinated by several oligodendrocytes, and one oligodendrocyte can provide myelin for multiple neurons. This is distinctive from the PNS where a single Schwann cell provides myelin for only one axon as the entire Schwann cell surrounds the axon. **Radial glia** serve as scaffolds for developing neurons as they migrate to their end destinations. **Ependymal** cells line fluid-filled ventricles of the brain and the central canal of the spinal cord. They are involved in the production of cerebrospinal fluid, which serves as a cushion for the brain, moves the fluid between the spinal cord and the brain, and is a component for the choroid plexus.

**Figure 26.7** Glial cells support neurons and maintain their environment. Glial cells of the (a) central nervous system include oligodendrocytes, astrocytes, ependymal cells, and microglial cells. Oligodendrocytes form the myelin sheath around axons. Astrocytes provide nutrients to neurons, maintain their extracellular environment, and provide structural support. Microglia scavenge pathogens and dead cells. Ependymal cells produce cerebrospinal fluid that cushions the neurons. Glial cells of the (b) peripheral nervous system include Schwann cells, which form the myelin sheath, and satellite cells, which provide nutrients and structural support to neurons.

**Figure 26.8** (a) Astrocytes and (b) oligodendrocytes are glial cells of the central nervous system. (credit a: modification of work by Uniformed Services University; credit b: modification of work by Jurjen Broeke; scale-bar data from Matt Russell)

## 26.2 | How Neurons Communicate

In this section, you will explore the following questions:

- What is the basis of the resting membrane potential?
- What are the stages of an action potential, and how are action potentials propagated?
- What are the similarities and differences between chemical and electrical synapses?
- What is long-term potentiation and long-term depression, and how do both relate to transmission of impulses across synapses?

### Connection for AP<sup>®</sup> Courses

The neuron is a great example of a structure-function relationship at the cellular level. Information flow along a neuron is usually from dendrite to axon and from neuron to neuron or from neuron to a cell of a target organ. Like other eukaryotic cells, neurons consist of a cell membrane, nucleus, and organelles, including mitochondria. **Action potentials** propagate impulses along neurons. When an axon is at rest, the membrane is said to be polarized; that is, there is an electrochemical gradient across it, with the inside of the membrane being more negatively charged than the outside. We explored the formation of electrochemical gradients using H<sup>+</sup> when we studied photosynthesis and cellular respiration. The neuron, however, uses Na<sup>+</sup> and K<sup>+</sup> to establish a gradient. It is also important to recall that ions cannot diffuse across the lipid bilayer of the cell membrane and must use transport proteins; in this case, the transport proteins are voltage-gated Na<sup>+</sup> and K<sup>+</sup> channels.

At rest, the Na<sup>+</sup>/K<sup>+</sup> pump, powered by ATP, maintains this gradient, known as resting **membrane potential**. In response to a stimulus, such as an odorant molecule, membrane potential changes, and an action potential is generated along the membrane as the voltage-gated Na<sup>+</sup> and K<sup>+</sup> channels open sequentially, causing the membrane to depolarize. In **depolarization**, the inside of the membrane becomes more positive than the outside as Na<sup>+</sup> flows to the inside. Repolarization occurs when K<sup>+</sup> flows across the membrane to the outside. In myelinated neurons, action potentials “jump” between gaps of unmyelinated axons (nodes of Ranvier), a phenomenon called saltatory conduction.

Transmission of a nerve impulse from one neuron to another or to another type of cell such as a muscle cell occurs across a junction called a synapse. **Synaptic vesicles** at the axon terminal of the presynaptic neuron release chemical messengers called neurotransmitters into the junction; neurotransmitters then bind to receptors embedded in the membrane of the postsynaptic neuron. Neurotransmitters may be either excitatory (such as acetylcholine or epinephrine) or inhibitory (such as serotonin or GABA) as they either increase or decrease the change of an action potential in the postsynaptic neuron. Many drugs, including both pharmaceuticals and drugs of abuse, can induce changes in synaptic transmission; for example, tetrahydrocannabinol (more commonly known as THC) in marijuana binds to a naturally occurring neurotransmitter

important to short-term memory.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>3.47</b> The student is able to create a visual representation of complex nervous systems to describe/explain how these systems detect external and internal signals, transmit and integrate information, and produce responses. |

All functions performed by the nervous system—from a simple motor reflex to more advanced functions like making a memory or a decision—require neurons to communicate with one another. While humans use words and body language to communicate, neurons use electrical and chemical signals. Just like a person in a committee, one neuron usually receives and synthesizes messages from multiple other neurons before “making the decision” to send the message on to other neurons.

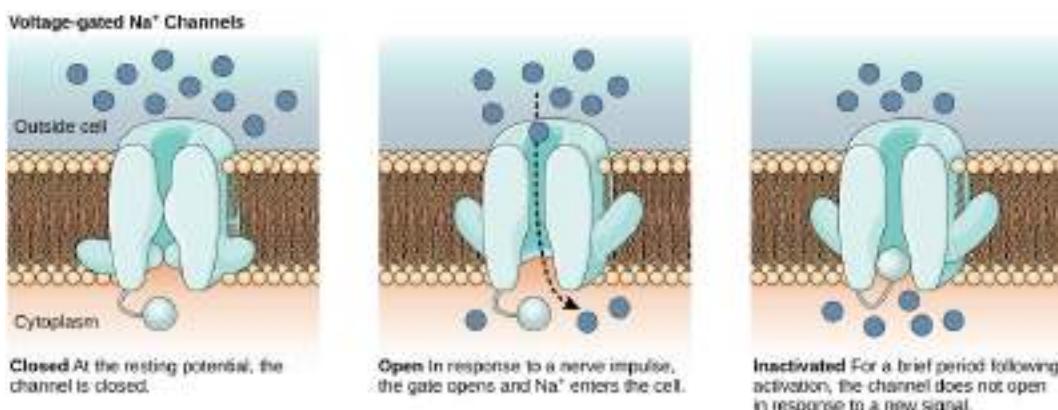

## Nerve Impulse Transmission within a Neuron

For the nervous system to function, neurons must be able to send and receive signals. These signals are possible because each neuron has a charged cellular membrane (a voltage difference between the inside and the outside), and the charge of this membrane can change in response to neurotransmitter molecules released from other neurons and environmental stimuli. To understand how neurons communicate, one must first understand the basis of the baseline or ‘resting’ membrane charge.

### Neuronal Charged Membranes

The lipid bilayer membrane that surrounds a neuron is impermeable to charged molecules or ions. To enter or exit the neuron, ions must pass through special proteins called ion channels that span the membrane. Ion channels have different configurations: open, closed, and inactive, as illustrated in **Figure 26.9**. Some ion channels need to be activated in order to open and allow ions to pass into or out of the cell. These ion channels are sensitive to the environment and can change their shape accordingly. Ion channels that change their structure in response to voltage changes are called voltage-gated ion

channels. Voltage-gated ion channels regulate the relative concentrations of different ions inside and outside the cell. The difference in total charge between the inside and outside of the cell is called the **membrane potential**.

**Figure 26.9** Voltage-gated ion channels open in response to changes in membrane voltage. After activation, they become inactivated for a brief period and will no longer open in response to a signal.

This **video** ([http://openstaxcollege.org/l/resting\\_neuron](http://openstaxcollege.org/l/resting_neuron)) discusses the basis of the resting membrane potential.

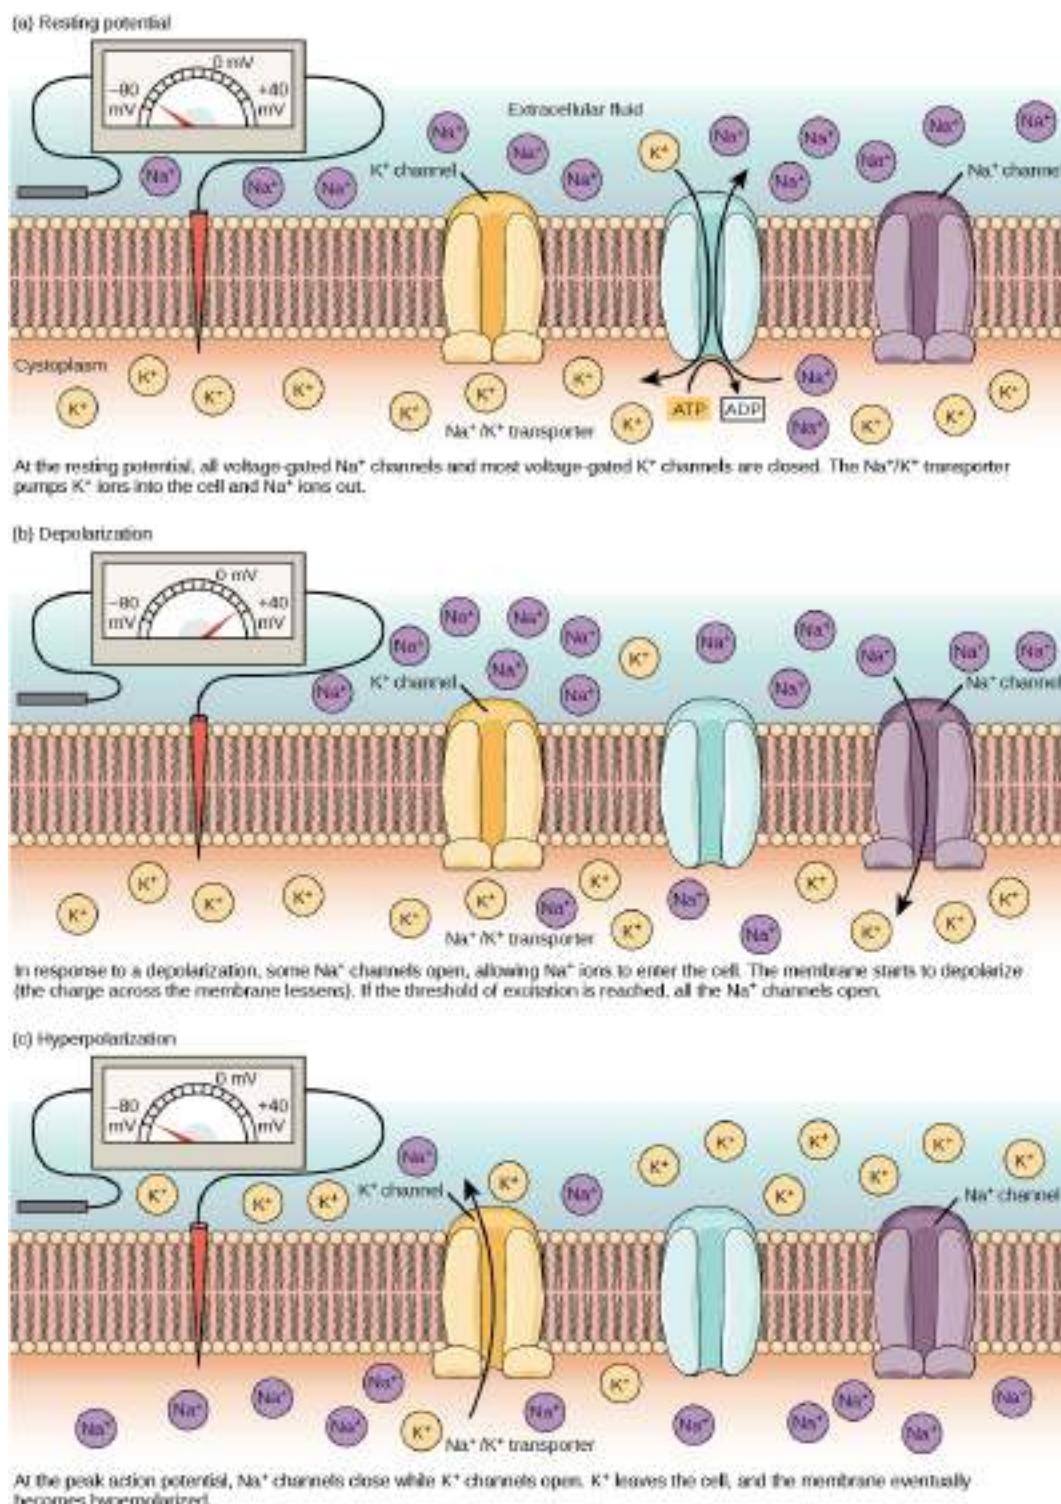

### Resting Membrane Potential

A neuron at rest is negatively charged: the inside of a cell is approximately 70 millivolts more negative than the outside ( $-70 \text{ mV}$ , note that this number varies by neuron type and by species). This voltage is called the resting membrane potential; it is caused by differences in the concentrations of ions inside and outside the cell. If the membrane were equally permeable to all ions, each type of ion would flow across the membrane and the system would reach equilibrium. Because ions cannot simply cross the membrane at will, there are different concentrations of several ions inside and outside the cell, as shown in **Table 26.1**. The difference in the number of positively charged potassium ions ( $\text{K}^+$ ) inside and outside the cell dominates the resting membrane potential (**Figure 26.10**). When the membrane is at rest,  $\text{K}^+$  ions accumulate inside the cell due to a net movement with the concentration gradient. The negative resting membrane potential is created and maintained by increasing the concentration of cations outside the cell (in the extracellular fluid) relative to inside the cell (in the cytoplasm). The negative charge within the cell is created by the cell membrane being more permeable to potassium ion movement than sodium ion movement. In neurons, potassium ions are maintained at high concentrations within the cell while sodium ions are maintained at high concentrations outside of the cell. The cell possesses potassium and sodium leakage channels that allow the two cations to diffuse down their concentration gradient. However, the neurons have far more potassium leakage channels than sodium leakage channels. Therefore, potassium diffuses out of the cell at a much faster rate than sodium leaks in. Because more cations are leaving the cell than are entering, this causes the interior of the cell to be negatively charged relative to the outside of the cell. The actions of the sodium potassium pump help to maintain the resting potential, once established. Recall that sodium potassium pumps brings two  $\text{K}^+$  ions into the cell while removing three  $\text{Na}^+$  ions per ATP consumed. As more cations are expelled from the cell than taken in, the inside of the cell remains negatively charged relative to the extracellular fluid. It should be noted that chloride ions ( $\text{Cl}^-$ ) tend to accumulate outside of the cell because they are repelled by negatively-charged proteins within the cytoplasm.

### Ion Concentration Inside and Outside Neurons

| Ion                              | Extracellular concentration (mM) | Intracellular concentration (mM) | Ratio outside/inside |
|----------------------------------|----------------------------------|----------------------------------|----------------------|
| Na <sup>+</sup>                  | 145                              | 12                               | 12                   |
| K <sup>+</sup>                   | 4                                | 155                              | 0.026                |
| Cl <sup>-</sup>                  | 120                              | 4                                | 30                   |
| Organic anions (A <sup>-</sup> ) | —                                | 100                              |                      |

**Table 26.1** The resting membrane potential is a result of different concentrations inside and outside the cell.

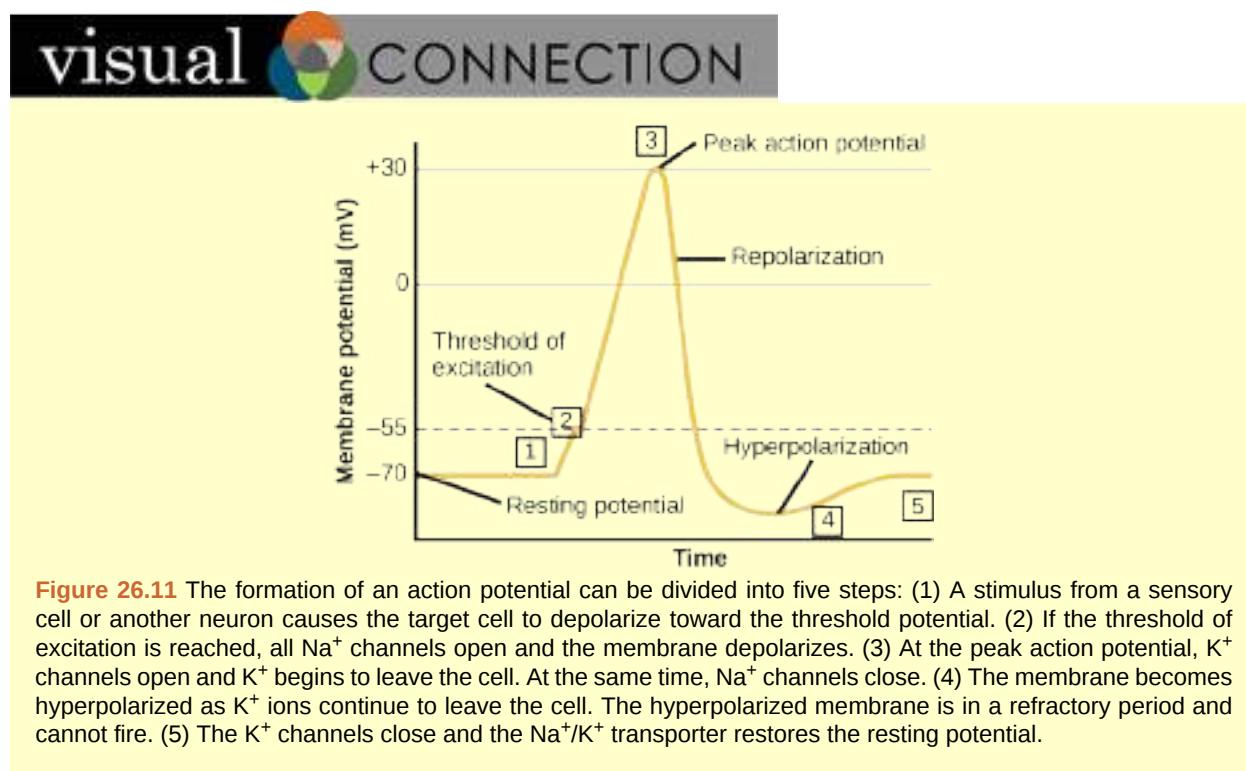

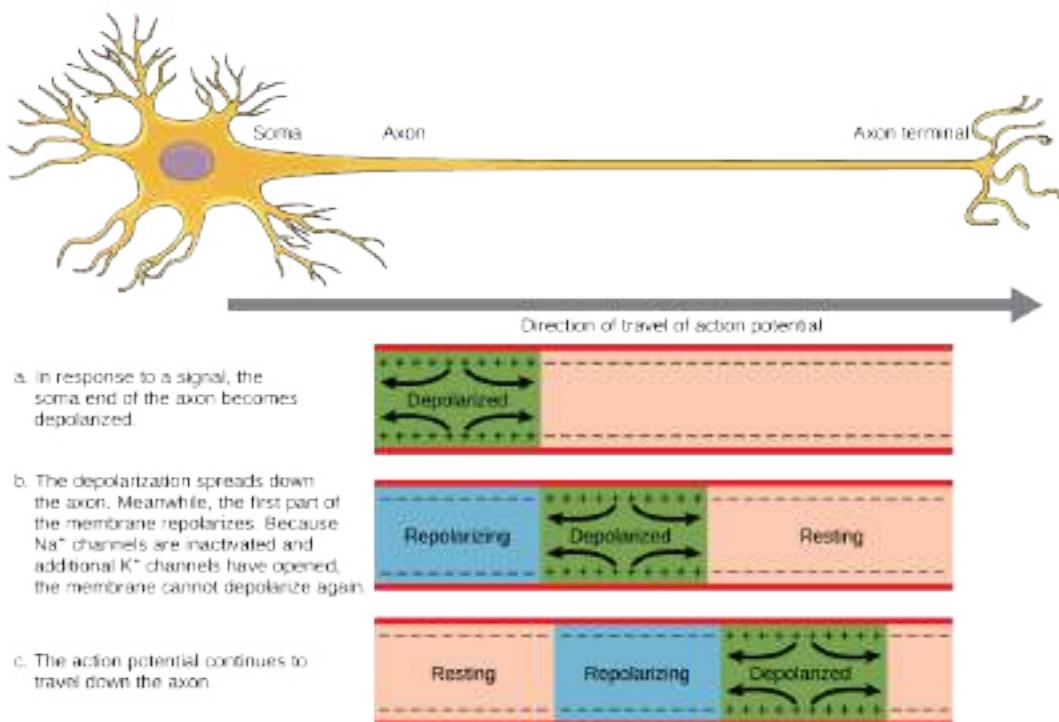

**Figure 26.10** The (a) resting membrane potential is a result of different concentrations of  $\text{Na}^+$  and  $\text{K}^+$  ions inside and outside the cell. A nerve impulse causes  $\text{Na}^+$  to enter the cell, resulting in (b) depolarization. At the peak action potential,  $\text{K}^+$  channels open and the cell becomes (c) hyperpolarized.

### Action Potential

A neuron can receive input from other neurons and, if this input is strong enough, send the signal to downstream neurons. Transmission of a signal between neurons is generally carried by a chemical called a neurotransmitter. Transmission of a signal within a neuron (from dendrite to axon terminal) is carried by a brief reversal of the resting membrane potential called an action potential. When neurotransmitter molecules bind to receptors located on a neuron's dendrites, ion channels

open. At excitatory synapses, this opening allows positive ions to enter the neuron and results in depolarization of the membrane—a decrease in the difference in voltage between the inside and outside of the neuron. A stimulus from a sensory cell or another neuron depolarizes the target neuron to its threshold potential (-55 mV).  $\text{Na}^+$  channels in the axon hillock open, allowing positive ions to enter the cell (Figure 26.10 and Figure 26.11). Once the sodium channels open, the neuron completely depolarizes to a membrane potential of about +40 mV. Action potentials are considered an "all-or nothing" event, in that, once the threshold potential is reached, the neuron always completely depolarizes. Once depolarization is complete, the cell must now "reset" its membrane voltage back to the resting potential. To accomplish this, the  $\text{Na}^+$  channels close and cannot be opened. This begins the neuron's **refractory period**, in which it cannot produce another action potential because its sodium channels will not open. At the same time, voltage-gated  $\text{K}^+$  channels open, allowing  $\text{K}^+$  to leave the cell. As  $\text{K}^+$  ions leave the cell, the membrane potential once again becomes negative. The diffusion of  $\text{K}^+$  out of the cell actually **hyperpolarizes** the cell, in that the membrane potential becomes more negative than the cell's normal resting potential. At this point, the sodium channels will return to their resting state, meaning they are ready to open again if the membrane potential again exceeds the threshold potential. Eventually the extra  $\text{K}^+$  ions diffuse out of the cell through the potassium leakage channels, bringing the cell from its hyperpolarized state, back to its resting membrane potential.

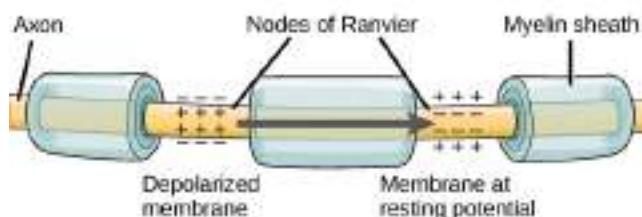

**Figure 26.12** The action potential is conducted down the axon as the axon membrane depolarizes, then repolarizes.

This **video** (<http://openstaxcollege.org/l/actionpotential>) presents an overview of action potential.

#### ***Myelin and the Propagation of the Action Potential***

For an action potential to communicate information to another neuron, it must travel along the axon and reach the axon terminals where it can initiate neurotransmitter release. The speed of conduction of an action potential along an axon is influenced by both the diameter of the axon and the axon's resistance to current leak. Myelin acts as an insulator that prevents current from leaving the axon; this increases the speed of action potential conduction. In demyelinating diseases like multiple sclerosis, action potential conduction slows because current leaks from previously insulated axon areas. The nodes of Ranvier, illustrated in **Figure 26.13** are gaps in the myelin sheath along the axon. These unmyelinated spaces are about one micrometer long and contain voltage gated  $\text{Na}^+$  and  $\text{K}^+$  channels. Flow of ions through these channels, particularly the  $\text{Na}^+$  channels, regenerates the action potential over and over again along the axon. This 'jumping' of the action potential from one node to the next is called **saltatory conduction**. If nodes of Ranvier were not present along an axon, the action potential would propagate very slowly since  $\text{Na}^+$  and  $\text{K}^+$  channels would have to continuously regenerate action potentials at every point along the axon instead of at specific points. Nodes of Ranvier also save energy for the neuron since the channels only need to be present at the nodes and not along the entire axon.

**Figure 26.13** Nodes of Ranvier are gaps in myelin coverage along axons. Nodes contain voltage-gated K<sup>+</sup> and Na<sup>+</sup> channels. Action potentials travel down the axon by jumping from one node to the next.

## Synaptic Transmission

The synapse or “gap” is the place where information is transmitted from one neuron to another. Synapses usually form between axon terminals and dendritic spines, but this is not universally true. There are also axon-to-axon, dendrite-to-dendrite, and axon-to-cell body synapses. The neuron transmitting the signal is called the presynaptic neuron, and the neuron receiving the signal is called the postsynaptic neuron. Note that these designations are relative to a particular synapse—most neurons are both presynaptic and postsynaptic. There are two types of synapses: chemical and electrical.

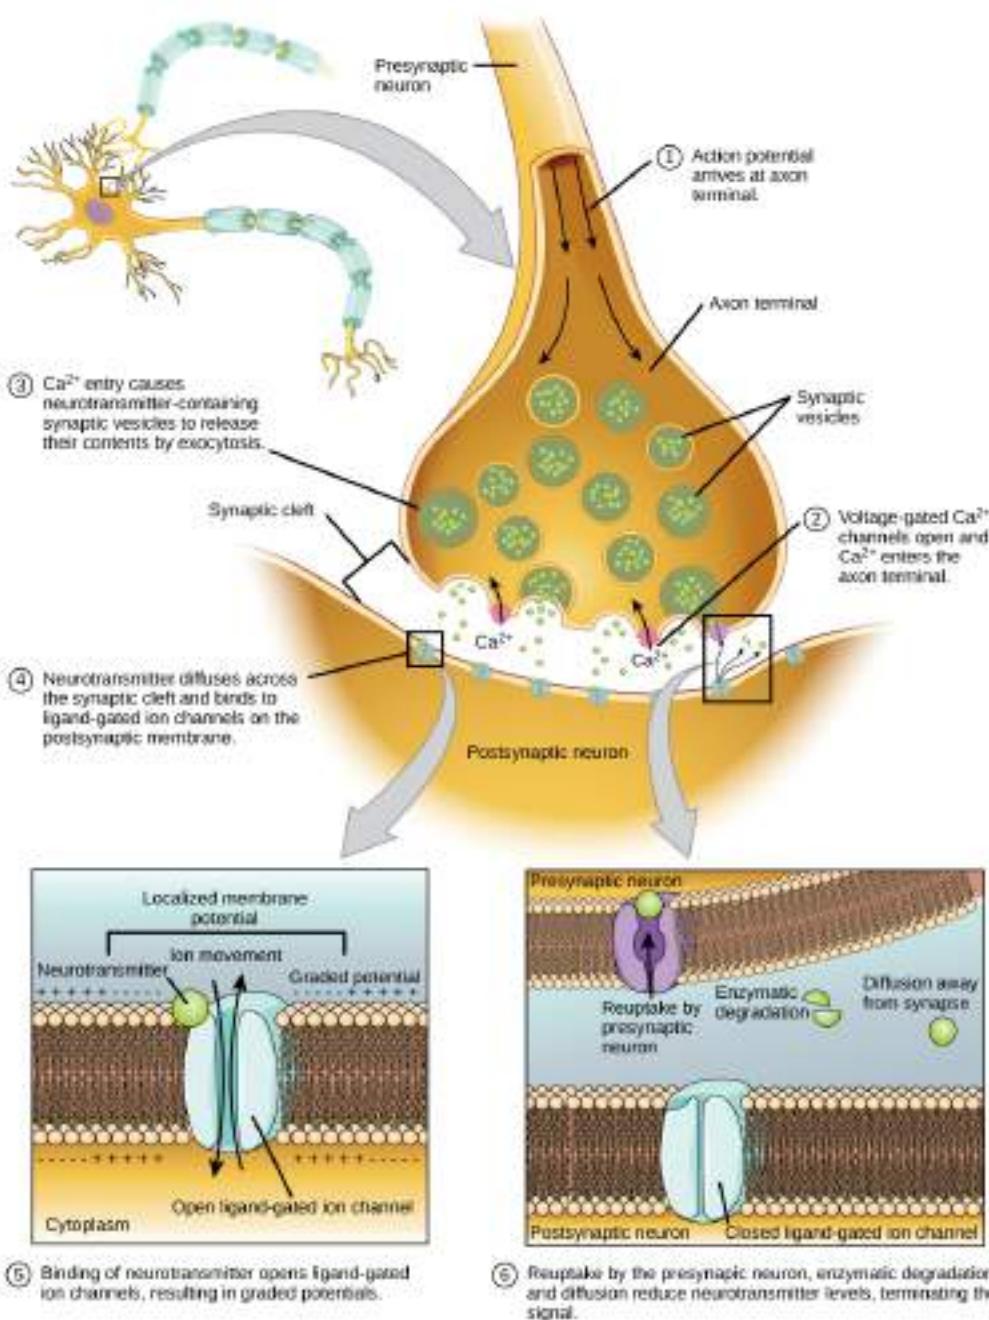

### Chemical Synapse

When an action potential reaches the axon terminal it depolarizes the membrane and opens voltage-gated Na<sup>+</sup> channels. Na<sup>+</sup> ions enter the cell, further depolarizing the presynaptic membrane. This depolarization causes voltage-gated Ca<sup>2+</sup> channels to open. Calcium ions entering the cell initiate a signaling cascade that causes small membrane-bound vesicles, called synaptic vesicles, containing neurotransmitter molecules to fuse with the presynaptic membrane. Synaptic vesicles are shown in **Figure 26.14**, which is an image from a scanning electron microscope.

**Figure 26.14** This pseudocolored image taken with a scanning electron microscope shows an axon terminal that was broken open to reveal synaptic vesicles (blue and orange) inside the neuron. (credit: modification of work by Tina Carvalho, NIH-NIGMS; scale-bar data from Matt Russell)

Fusion of a vesicle with the presynaptic membrane causes neurotransmitter to be released into the **synaptic cleft**, the extracellular space between the presynaptic and postsynaptic membranes, as illustrated in **Figure 26.15**. The neurotransmitter diffuses across the synaptic cleft and binds to receptor proteins on the postsynaptic membrane.

**Figure 26.15** Communication at chemical synapses requires release of neurotransmitters. When the presynaptic membrane is depolarized, voltage-gated  $\text{Ca}^{2+}$  channels open and allow  $\text{Ca}^{2+}$  to enter the cell. The calcium entry causes synaptic vesicles to fuse with the membrane and release neurotransmitter molecules into the synaptic cleft. The neurotransmitter diffuses across the synaptic cleft and binds to ligand-gated ion channels in the postsynaptic membrane, resulting in a localized depolarization or hyperpolarization of the postsynaptic neuron.

The binding of a specific neurotransmitter causes particular ion channels, in this case ligand-gated channels, on the postsynaptic membrane to open. Neurotransmitters can either have excitatory or inhibitory effects on the postsynaptic membrane, as detailed in **Table 26.1**. For example, when acetylcholine is released at the synapse between a nerve and muscle (called the neuromuscular junction) by a presynaptic neuron, it causes postsynaptic  $\text{Na}^+$  channels to open.  $\text{Na}^+$  enters the postsynaptic cell and causes the postsynaptic membrane to depolarize. This depolarization is called an **excitatory postsynaptic potential (EPSP)** and makes the postsynaptic neuron more likely to fire an action potential. Release of neurotransmitter at inhibitory synapses causes **inhibitory postsynaptic potentials (IPSPs)**, a hyperpolarization of the presynaptic membrane. For example, when the neurotransmitter GABA (gamma-aminobutyric acid) is released from a presynaptic neuron, it binds to and opens  $\text{Cl}^-$  channels.  $\text{Cl}^-$  ions enter the cell and hyperpolarizes the membrane, making the

neuron less likely to fire an action potential.

Once neurotransmission has occurred, the neurotransmitter must be removed from the synaptic cleft so the postsynaptic membrane can “reset” and be ready to receive another signal. This can be accomplished in three ways: the neurotransmitter can diffuse away from the synaptic cleft, it can be degraded by enzymes in the synaptic cleft, or it can be recycled (sometimes called reuptake) by the presynaptic neuron. Several drugs act at this step of neurotransmission. For example, some drugs that are given to Alzheimer’s patients work by inhibiting acetylcholinesterase, the enzyme that degrades acetylcholine. This inhibition of the enzyme essentially increases neurotransmission at synapses that release acetylcholine. Once released, the acetylcholine stays in the cleft and can continually bind and unbind to postsynaptic receptors.

### Neurotransmitter Examples and Location

| Neurotransmitter | Example                                                | Location       |
|------------------|--------------------------------------------------------|----------------|
| Acetylcholine    | —                                                      | CNS and/or PNS |
| Biogenic amine   | Dopamine, serotonin, norepinephrine                    | CNS and/or PNS |
| Amino acid       | Glycine, glutamate, aspartate, gamma aminobutyric acid | CNS            |
| Neuropeptide     | Substance P, endorphins                                | CNS and/or PNS |

**Table 26.2**

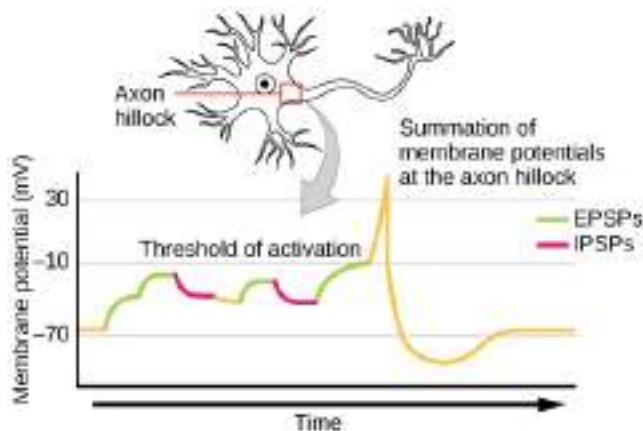

### *Electrical Synapse*

While electrical synapses are fewer in number than chemical synapses, they are found in all nervous systems and play important and unique roles. The mode of neurotransmission in electrical synapses is quite different from that in chemical synapses. In an electrical synapse, the presynaptic and postsynaptic membranes are very close together and are actually physically connected by channel proteins forming gap junctions. Gap junctions allow current to pass directly from one cell to the next. In addition to the ions that carry this current, other molecules, such as ATP, can diffuse through the large gap junction pores.

There are key differences between chemical and electrical synapses. Because chemical synapses depend on the release of neurotransmitter molecules from synaptic vesicles to pass on their signal, there is an approximately one millisecond delay between when the axon potential reaches the presynaptic terminal and when the neurotransmitter leads to opening of postsynaptic ion channels. Additionally, this signaling is unidirectional. Signaling in electrical synapses, in contrast, is virtually instantaneous (which is important for synapses involved in key reflexes), and some electrical synapses are bidirectional. Electrical synapses are also more reliable as they are less likely to be blocked, and they are important for synchronizing the electrical activity of a group of neurons. For example, electrical synapses in the thalamus are thought to regulate slow-wave sleep, and disruption of these synapses can cause seizures.

### Signal Summation

Sometimes a single excitatory postsynaptic potential (EPSP) is strong enough to induce an action potential in the postsynaptic neuron, but often multiple presynaptic inputs must create EPSPs around the same time for the postsynaptic neuron to be sufficiently depolarized to fire an action potential. This process is called **summation** and occurs at the axon hillock, as illustrated in **Figure 26.16**. Additionally, one neuron often has inputs from many presynaptic neurons—some excitatory and some inhibitory—so IPSPs can cancel out EPSPs and vice versa. It is the net change in postsynaptic membrane voltage that determines whether the postsynaptic cell has reached its threshold of excitation needed to fire an action potential. Together, synaptic summation and the threshold for excitation act as a filter so that random “noise” in the system is not transmitted as important information.

**Figure 26.16** A single neuron can receive both excitatory and inhibitory inputs from multiple neurons, resulting in local membrane depolarization (EPSP input) and hyperpolarization (IPSP input). All these inputs are added together at the axon hillock. If the EPSPs are strong enough to overcome the IPSPs and reach the threshold of excitation, the neuron will fire.

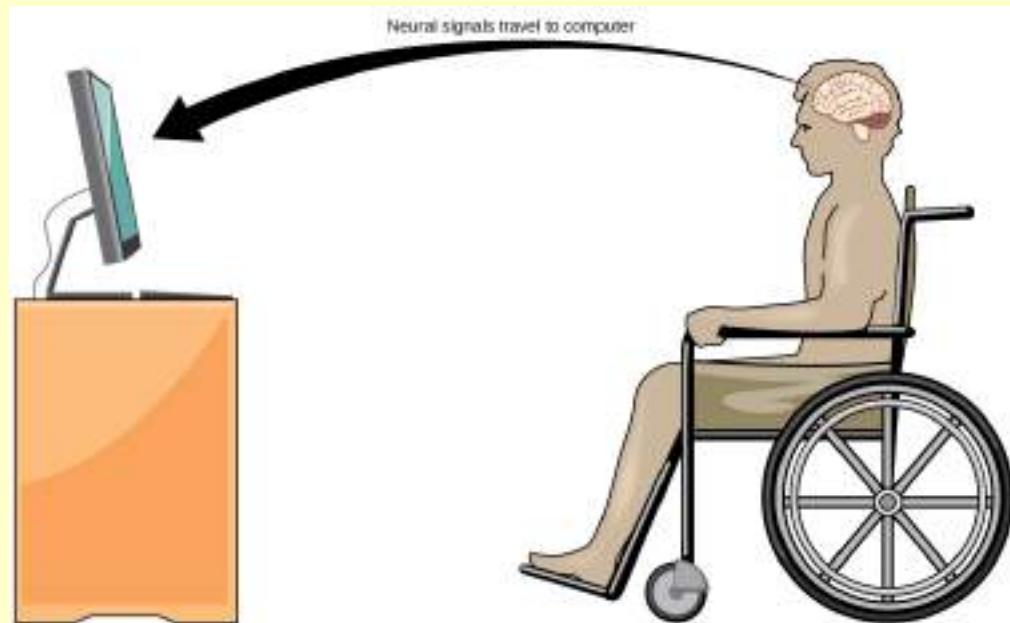

## everyday CONNECTION

### Brain-computer interface

Amyotrophic lateral sclerosis (ALS, also called Lou Gehrig's Disease) is a neurological disease characterized by the degeneration of the motor neurons that control voluntary movements. The disease begins with muscle weakening and lack of coordination and eventually destroys the neurons that control speech, breathing, and swallowing; in the end, the disease can lead to paralysis. At that point, patients require assistance from machines to be able to breathe and to communicate. Several special technologies have been developed to allow "locked-in" patients to communicate with the rest of the world. One technology, for example, allows patients to type out sentences by twitching their cheek. These sentences can then be read aloud by a computer.

A relatively new line of research for helping paralyzed patients, including those with ALS, to communicate and retain a degree of self-sufficiency is called brain-computer interface (BCI) technology and is illustrated in **Figure 26.17**. This technology sounds like something out of science fiction: it allows paralyzed patients to control a computer using only their thoughts. There are several forms of BCI. Some forms use EEG recordings from electrodes taped onto the skull. These recordings contain information from large populations of neurons that can be decoded by a computer. Other forms of BCI require the implantation of an array of electrodes smaller than a postage stamp in the arm and hand area of the motor cortex. This form of BCI, while more invasive, is very powerful as each electrode can record actual action potentials from one or more neurons. These signals are then sent to a computer, which has been trained to decode the signal and feed it to a tool—such as a cursor on a computer screen. This means that a patient with ALS can use e-mail, read the Internet, and communicate with others by thinking of moving his or her hand or arm (even though the paralyzed patient cannot make that bodily movement). Recent advances have allowed a paralyzed locked-in patient who suffered a stroke 15 years ago to control a robotic arm and even to feed herself coffee using BCI technology.

Despite the amazing advancements in BCI technology, it also has limitations. The technology can require many hours of training and long periods of intense concentration for the patient; it can also require brain surgery to implant the devices.

**Figure 26.17** With brain-computer interface technology, neural signals from a paralyzed patient are collected, decoded, and then fed to a tool, such as a computer, a wheelchair, or a robotic arm.

Watch [this video](http://openstaxcollege.org/l/paralyzation) (<http://openstaxcollege.org/l/paralyzation>) in which a paralyzed woman use a brain-controlled robotic arm to bring a drink to her mouth, among other images of brain-computer interface technology in action.

## Synaptic Plasticity

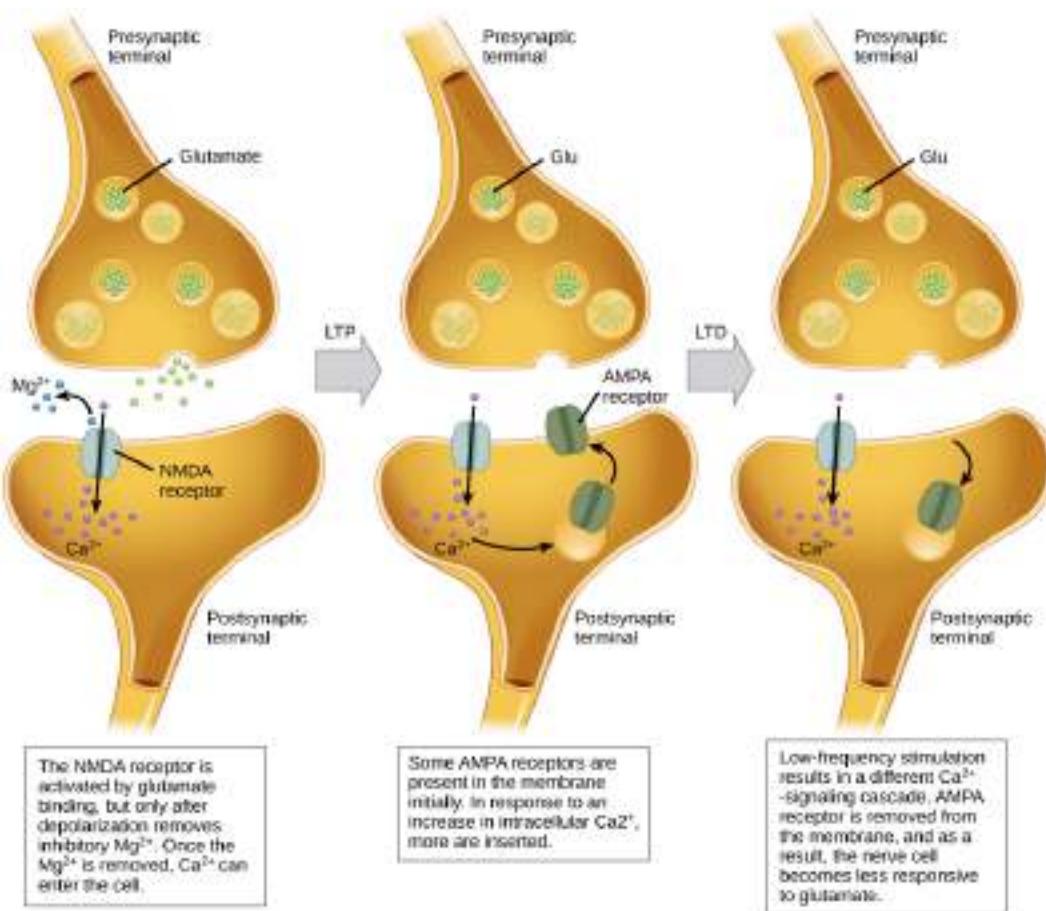

Synapses are not static structures. They can be weakened or strengthened. They can be broken, and new synapses can be made. Synaptic plasticity allows for these changes, which are all needed for a functioning nervous system. In fact, synaptic plasticity is the basis of learning and memory. Two processes in particular, long-term potentiation (LTP) and long-term depression (LTD) are important forms of synaptic plasticity that occur in synapses in the hippocampus, a brain region that is involved in storing memories.

### Long-term Potentiation (LTP)

**Long-term potentiation (LTP)** is a persistent strengthening of a synaptic connection. LTP is based on the Hebbian principle: cells that fire together wire together. There are various mechanisms, none fully understood, behind the synaptic strengthening seen with LTP. One known mechanism involves a type of postsynaptic glutamate receptor, called NMDA (N-Methyl-D-aspartate) receptors, shown in [Figure 26.18](#). These receptors are normally blocked by magnesium ions; however, when the postsynaptic neuron is depolarized by multiple presynaptic inputs in quick succession (either from one neuron or multiple neurons), the magnesium ions are forced out allowing  $\text{Ca}^{2+}$  ions to pass into the postsynaptic cell. Next,  $\text{Ca}^{2+}$  ions entering the cell initiate a signaling cascade that causes a different type of glutamate receptor, called AMPA ( $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid) receptors, to be inserted into the postsynaptic membrane, since activated AMPA receptors allow positive ions to enter the cell. So, the next time glutamate is released from the presynaptic membrane, it will have a larger excitatory effect (EPSP) on the postsynaptic cell because the binding of glutamate to these AMPA receptors will allow more positive ions into the cell. The insertion of additional AMPA receptors strengthens the synapse and means that the postsynaptic neuron is more likely to fire in response to presynaptic neurotransmitter release.

### Long-term Depression (LTD)

**Long-term depression (LTD)** is essentially the reverse of LTP: it is a long-term weakening of a synaptic connection. One mechanism known to cause LTD also involves AMPA receptors. In this situation, calcium that enters through NMDA receptors initiates a different signaling cascade, which results in the removal of AMPA receptors from the postsynaptic membrane, as illustrated in [Figure 26.18](#). The decrease in AMPA receptors in the membrane makes the postsynaptic neuron less responsive to glutamate released from the presynaptic neuron. While it may seem counterintuitive, LTD may be just as important for learning and memory as LTP. The weakening and pruning of unused synapses allows for unimportant connections to be lost and makes the synapses that have undergone LTP that much stronger by comparison.

**Figure 26.18** Calcium entry through postsynaptic NMDA receptors can initiate two different forms of synaptic plasticity: long-term potentiation (LTP) and long-term depression (LTD). LTP arises when a single synapse is repeatedly stimulated. This stimulation causes a calcium- and CaMKII-dependent cellular cascade, which results in the insertion of more AMPA receptors into the postsynaptic membrane. The next time glutamate is released from the presynaptic cell, it will bind to both NMDA and the newly inserted AMPA receptors, thus depolarizing the membrane more efficiently. LTD occurs when few glutamate molecules bind to NMDA receptors at a synapse (due to a low firing rate of the presynaptic neuron). The calcium that does flow through NMDA receptors initiates a different calcineurin and protein phosphatase 1-dependent cascade, which results in the endocytosis of AMPA receptors. This makes the postsynaptic neuron less responsive to glutamate released from the presynaptic neuron.

### Activity

Don't Eat the Fugu: Understanding the Neuron. Create a model of a neuron to explain how the vertebrate nervous system detects signals and transmits information. Then use the model to predict how abnormal cell structure, drugs, and toxins (such as tetrodotoxin found in fugu/pufferfish) can affect impulse transmission.

### Think About It

Potassium channel blockers, such as procainamide, are often used to treat abnormal activity in the heart. These channel blocks impede the movement of K<sup>+</sup> through voltage-gated K<sup>+</sup> channels. What is the likely effect(s) of these medications on action potentials?

## 26.3 | The Central Nervous System

In this section, you will explore the following questions:

- What are the major areas of the brain?
- What are the primary functions of the spinal cord, cerebral lobes, cerebellum, and brainstem?

### Connection for AP® Courses

The central nervous system (CNS) consists of the brain and **spinal cord**, both of which are protected by the skull and vertebral column, respectively. The CNS receives sensory information, integrates this information, and initiates a motor response, with the brain serving as the control center for processing sensory information and directing responses. Different parts of the vertebrate brain (including ours) have different functions, and brain development in animals reveals a unique evolutionary progression. You do not have to memorize all the different parts of the brain and their functions for AP. However, as a student of biology, you should have a general understanding of the three major parts of the brain and their functions.

In mammals, the parts of the brain include the cerebrum or cortex (which can be broken down into four primary lobes: frontal, temporal, occipital, and parietal), basal ganglia, thalamus, hypothalamus, limbic system, **cerebellum**, and **brainstem**. Information traveling up the spinal cord to the brain is directed to one of the specialized areas of the cerebrum; for example, association areas for hearing are localized in the temporal lobe. The cerebellum helps coordinate skeletal muscle activity, and the medulla oblongata and pons in the brainstem are centers for vital functions, such as breathing and heart rate. Although localization of functions occurs, most complex functions, like language, involve neurons in multiple brain regions. In terms of energy, since the brain consumes about 20 percent of the body's resources (ATP), is it any wonder that you're exhausted after taking an AP® test? Information from the brain travels down the spinal cord, making connections with peripheral nerves; thus, the spinal cord transmits sensory and motor input and controls motor reflexes, like the automatic responses when the pupils of your eye constrict in bright sunlight or when your jerk your hand away from something hot.

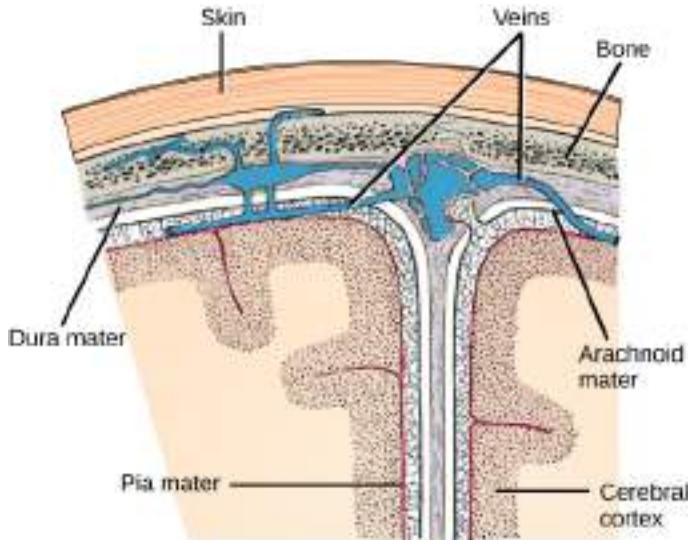

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

As mentioned above, the central nervous system (CNS) is made up of the brain, a part of which is shown in **Figure 26.19** and spinal cord and is covered with three layers of protective coverings called **meninges** (from the Greek word for membrane). The outermost layer is the **dura mater** (Latin for “hard mother”). As the Latin suggests, the primary function for this thick layer is to protect the brain and spinal cord. The dura mater also contains vein-like structures that carry blood from the brain back to the heart. The middle layer is the web-like **arachnoid mater**. The last layer is the **pia mater** (Latin for “soft mother”), which directly contacts and covers the brain and spinal cord like plastic wrap. The space between the arachnoid and pia maters is filled with **cerebrospinal fluid (CSF)**. CSF is produced by a tissue called **choroid plexus** in fluid-filled compartments in the CNS called **ventricles**. The brain floats in CSF, which acts as a cushion and shock absorber and makes the brain neutrally buoyant. CSF also functions to circulate chemical substances throughout the brain and into the spinal cord.

The entire brain contains only about 8.5 tablespoons of CSF, but CSF is constantly produced in the ventricles. This creates a problem when a ventricle is blocked—the CSF builds up and creates swelling and the brain is pushed against the skull. This swelling condition is called hydrocephalus (“water head”) and can cause seizures, cognitive problems, and even death if a shunt is not inserted to remove the fluid and pressure.

**Figure 26.19** The cerebral cortex is covered by three layers of meninges: the dura, arachnoid, and pia maters. (credit: modification of work by Gray's Anatomy)

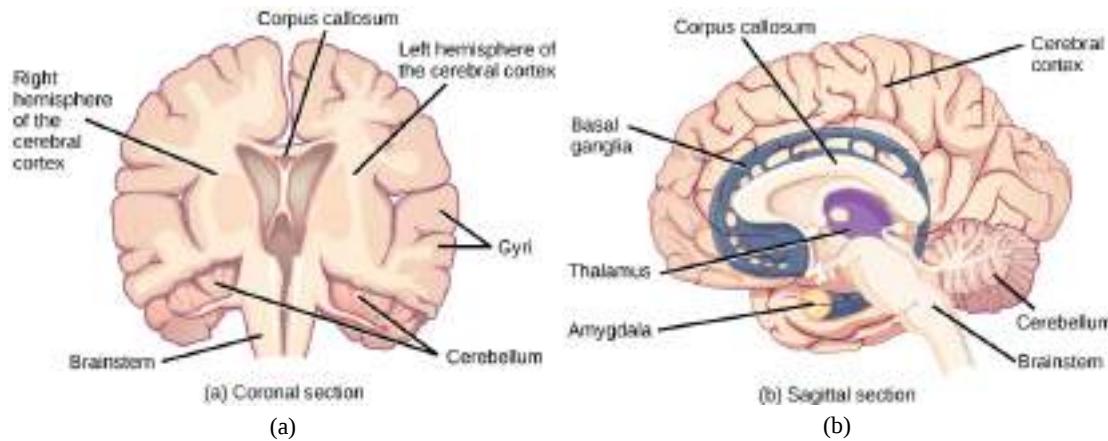

## Brain

The brain is the part of the central nervous system that is contained in the cranial cavity of the skull. It includes the cerebral cortex, limbic system, basal ganglia, thalamus, hypothalamus, and cerebellum. There are three different ways that a brain can be sectioned in order to view internal structures: a sagittal section cuts the brain left to right, as shown in **Figure 26.21b**, a coronal section cuts the brain front to back, as shown in **Figure 26.20a**, and a horizontal section cuts the brain top to bottom.

### Cerebral Cortex

The outermost part of the brain is a thick piece of nervous system tissue called the **cerebral cortex**, which is folded into hills called **gyri** (singular: gyrus) and valleys called **sulci** (singular: sulcus). The cortex is made up of two hemispheres—right and left—which are separated by a large sulcus. A thick fiber bundle called the **corpus callosum** (Latin: “tough body”) connects the two hemispheres and allows information to be passed from one side to the other. Although there are some

brain functions that are localized more to one hemisphere than the other, the functions of the two hemispheres are largely redundant. In fact, sometimes (very rarely) an entire hemisphere is removed to treat severe epilepsy. While patients do suffer some deficits following the surgery, they can have surprisingly few problems, especially when the surgery is performed on children who have very immature nervous systems.

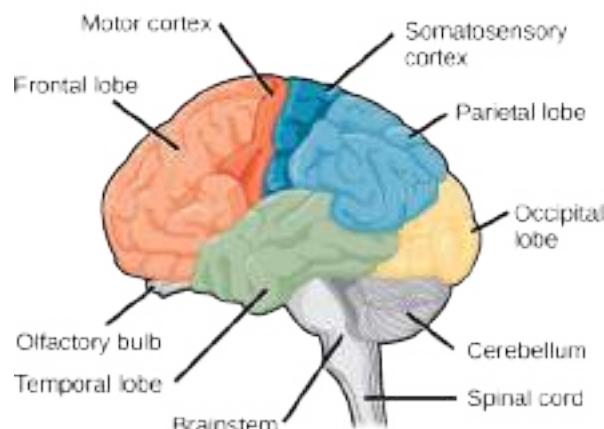

**Figure 26.20** These illustrations show the (a) coronal and (b) sagittal sections of the human brain.

In other surgeries to treat severe epilepsy, the corpus callosum is cut instead of removing an entire hemisphere. This causes a condition called split-brain, which gives insights into unique functions of the two hemispheres. For example, when an object is presented to patients' left visual field, they may be unable to verbally name the object (and may claim to not have seen an object at all). This is because the visual input from the left visual field crosses and enters the right hemisphere and cannot then signal to the speech center, which generally is found in the left side of the brain. Remarkably, if a split-brain patient is asked to pick up a specific object out of a group of objects with the left hand, the patient will be able to do so but will still be unable to vocally identify it.

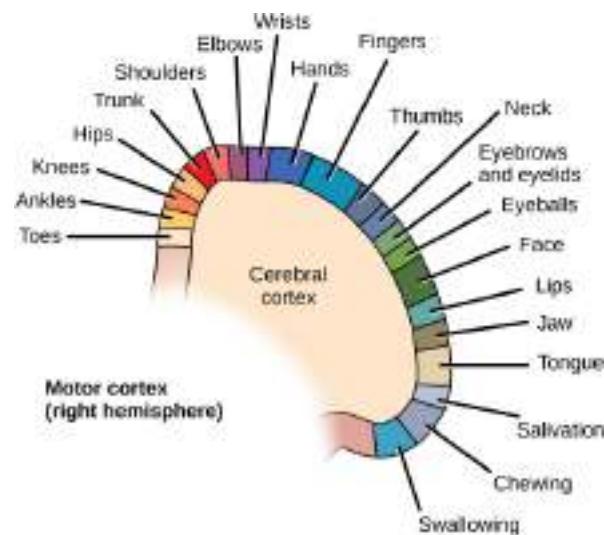

See **this website** (<http://openstaxcollege.org/l/split-brain>) to learn more about split-brain patients and to play a game where you can model the split-brain experiments yourself.

Each cortical hemisphere contains regions called lobes that are involved in different functions. Scientists use various techniques to determine what brain areas are involved in different functions: they examine patients who have had injuries or diseases that affect specific areas and see how those areas are related to functional deficits. They also conduct animal studies where they stimulate brain areas and see if there are any behavioral changes. They use a technique called transmagnetic stimulation (TMS) to temporarily deactivate specific parts of the cortex using strong magnets placed outside the head; and they use functional magnetic resonance imaging (fMRI) to look at changes in oxygenated blood flow in particular brain regions that correlate with specific behavioral tasks. These techniques, and others, have given great insight into the functions of different brain regions but have also showed that any given brain area can be involved in more than one behavior or process, and any given behavior or process generally involves neurons in multiple brain areas. That being said, each hemisphere of the mammalian cerebral cortex can be broken down into four functionally and spatially defined lobes: frontal, parietal, temporal, and occipital. **Figure 26.21** illustrates these four lobes of the human cerebral cortex.

**Figure 26.21** The human cerebral cortex includes the frontal, parietal, temporal, and occipital lobes.

The **frontal lobe** is located at the front of the brain, over the eyes. This lobe contains the olfactory bulb, which processes smells. The frontal lobe also contains the motor cortex, which is important for planning and implementing movement. Areas within the motor cortex map to different muscle groups, and there is some organization to this map, as shown in **Figure 26.22**. For example, the neurons that control movement of the fingers are next to the neurons that control movement of the hand. Neurons in the frontal lobe also control cognitive functions like maintaining attention, speech, and decision-making. Studies of humans who have damaged their frontal lobes show that parts of this area are involved in personality, socialization, and assessing risk.

**Figure 26.22** Different parts of the motor cortex control different muscle groups. Muscle groups that are neighbors in the body are generally controlled by neighboring regions of the motor cortex as well. For example, the neurons that control finger movement are near the neurons that control hand movement.

The **parietal lobe** is located at the top of the brain. Neurons in the parietal lobe are involved in speech and also reading. Two of the parietal lobe's main functions are processing **somatosensation**—touch sensations like pressure, pain, heat, cold—and processing **proprioception**—the sense of how parts of the body are oriented in space. The parietal lobe contains a somatosensory map of the body similar to the motor cortex.

The **occipital lobe** is located at the back of the brain. It is primarily involved in vision—seeing, recognizing, and identifying the visual world.

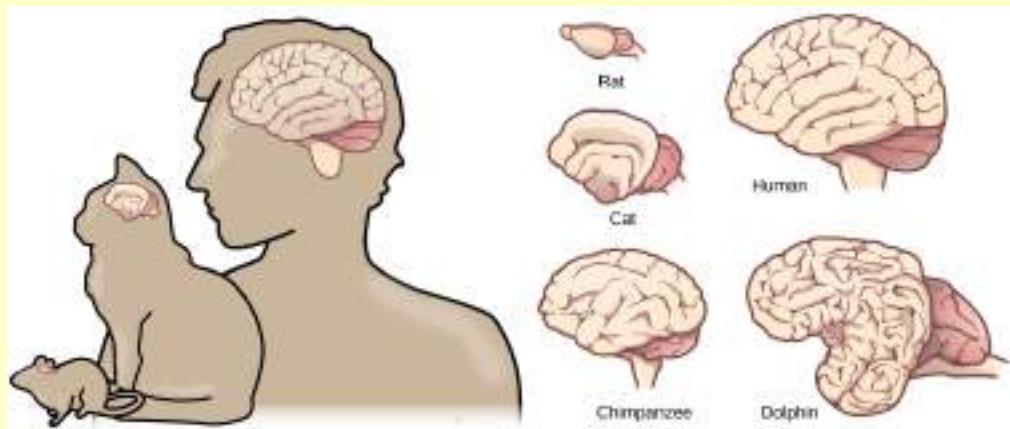

The **temporal lobe** is located at the base of the brain by your ears and is primarily involved in processing and interpreting sounds. It also contains the **hippocampus** (Greek for “seahorse”)—a structure that processes memory formation. The hippocampus is illustrated in **Figure 26.24**. The role of the hippocampus in memory was partially determined by studying one famous epileptic patient, HM, who had both sides of his hippocampus removed in an attempt to cure his epilepsy. His seizures went away, but he could no longer form new memories (although he could remember some facts from before his

surgery and could learn new motor tasks).

## evolution CONNECTION

### Cerebral Cortex

Compared to other vertebrates, mammals have exceptionally large brains for their body size. An entire alligator's brain, for example, would fill about one and a half teaspoons. This increase in brain to body size ratio is especially pronounced in apes, whales, and dolphins. While this increase in overall brain size doubtlessly played a role in the evolution of complex behaviors unique to mammals, it does not tell the whole story. Scientists have found a relationship between the relatively high surface area of the cortex and the intelligence and complex social behaviors exhibited by some mammals. This increased surface area is due, in part, to increased folding of the cortical sheet (more sulci and gyri). For example, a rat cortex is very smooth with very few sulci and gyri. Cat and sheep cortices have more sulci and gyri. Chimps, humans, and dolphins have even more.

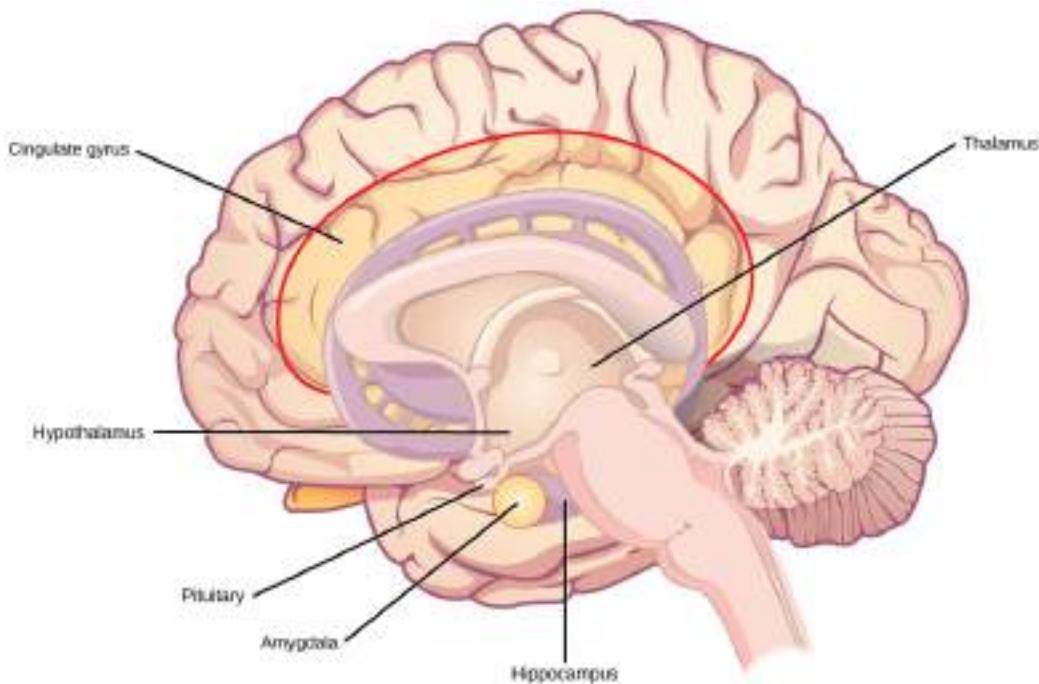

**Figure 26.23** Mammals have larger brain-to-body ratios than other vertebrates. Within mammals, increased cortical folding and surface area is correlated with complex behavior.

### Basal Ganglia

Interconnected brain areas called the **basal ganglia** (or **basal nuclei**), shown in **Figure 26.20b**, play important roles in movement control and posture. Damage to the basal ganglia, as in Parkinson's disease, leads to motor impairments like a shuffling gait when walking. The basal ganglia also regulate motivation. For example, when a wasp sting led to bilateral basal ganglia damage in a 25-year-old businessman, he began to spend all his days in bed and showed no interest in anything or anybody. But when he was externally stimulated—as when someone asked to play a card game with him—he was able to function normally. Interestingly, he and other similar patients do not report feeling bored or frustrated by their state.

### Thalamus

The **thalamus** (Greek for “inner chamber”), illustrated in **Figure 26.24**, acts as a gateway to and from the cortex. It receives sensory and motor inputs from the body and also receives feedback from the cortex. This feedback mechanism can modulate conscious awareness of sensory and motor inputs depending on the attention and arousal state of the animal. The thalamus helps regulate consciousness, arousal, and sleep states. A rare genetic disorder called fatal familial insomnia causes the degeneration of thalamic neurons and glia. This disorder prevents affected patients from being able to sleep, among other symptoms, and is eventually fatal.

**Figure 26.24** The limbic system regulates emotion and other behaviors. It includes parts of the cerebral cortex located near the center of the brain, including the cingulate gyrus and the hippocampus as well as the thalamus, hypothalamus and amygdala.

### Hypothalamus

Below the thalamus is the **hypothalamus**, shown in [Figure 26.24](#). The hypothalamus controls the endocrine system by sending signals to the pituitary gland, a pea-sized endocrine gland that releases several different hormones that affect other glands as well as other cells. This relationship means that the hypothalamus regulates important behaviors that are controlled by these hormones. The hypothalamus is the body's thermostat—it makes sure key functions like food and water intake, energy expenditure, and body temperature are kept at appropriate levels. Neurons within the hypothalamus also regulate circadian rhythms, sometimes called sleep cycles.

### Limbic System

The **limbic system** is a connected set of structures that regulates emotion, as well as behaviors related to fear and motivation. It plays a role in memory formation and includes parts of the thalamus and hypothalamus as well as the hippocampus. One important structure within the limbic system is a temporal lobe structure called the **amygdala** (Greek for “almond”), illustrated in [Figure 26.24](#). The two amygdala are important both for the sensation of fear and for recognizing fearful faces. The **cingulate gyrus** helps regulate emotions and pain.

### Cerebellum

The cerebellum (Latin for “little brain”), shown in [Figure 26.21](#), sits at the base of the brain on top of the brainstem. The cerebellum controls balance and aids in coordinating movement and learning new motor tasks.

### Brainstem

The brainstem, illustrated in [Figure 26.21](#), connects the rest of the brain with the spinal cord. It consists of the midbrain, medulla oblongata, and the pons. Motor and sensory neurons extend through the brainstem allowing for the relay of signals between the brain and spinal cord. Ascending neural pathways cross in this section of the brain allowing the left hemisphere of the cerebrum to control the right side of the body and vice versa. The brainstem coordinates motor control signals sent from the brain to the body. The brainstem controls several important functions of the body including alertness, arousal, breathing, blood pressure, digestion, heart rate, swallowing, walking, and sensory and motor information integration.

## science practices CONNECTION for AP<sup>®</sup> Courses

### Activity

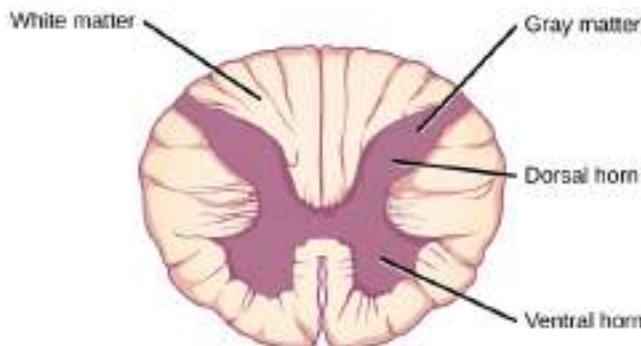

Create a representation to illustrate what parts of the brain allow you to perform a favorite daily activity, like kicking a soccer ball, learning a new dance move, or reading the information in this section of the text and jotting down a few notes.

## Spinal Cord

Connecting to the brainstem and extending down the body through the spinal column is the spinal cord, shown in **Figure 26.21**. The spinal cord is a thick bundle of nerve tissue that carries information about the body to the brain and from the brain to the body. The spinal cord is contained within the bones of the vertebrate column but is able to communicate signals to and from the body through its connections with spinal nerves (part of the peripheral nervous system). A cross-section of the spinal cord looks like a white oval containing a gray butterfly-shape, as illustrated in **Figure 26.25**. Myelinated axons make up the “white matter” and neuron and glial cell bodies make up the “gray matter.” Gray matter is also composed of interneurons, which connect two neurons each located in different parts of the body. Axons and cell bodies in the dorsal (facing the back of the animal) spinal cord convey mostly sensory information from the body to the brain. Axons and cell bodies in the ventral (facing the front of the animal) spinal cord primarily transmit signals controlling movement from the brain to the body.

The spinal cord also controls motor reflexes. These reflexes are quick, unconscious movements—like automatically removing a hand from a hot object. Reflexes are so fast because they involve local synaptic connections. For example, the knee reflex that a doctor tests during a routine physical is controlled by a single synapse between a sensory neuron and a motor neuron. While a reflex may only require the involvement of one or two synapses, synapses with interneurons in the spinal column transmit information to the brain to convey what happened (the knee jerked, or the hand was hot).

In the United States, there around 10,000 spinal cord injuries each year. Because the spinal cord is the information superhighway connecting the brain with the body, damage to the spinal cord can lead to paralysis. The extent of the paralysis depends on the location of the injury along the spinal cord and whether the spinal cord was completely severed. For example, if the spinal cord is damaged at the level of the neck, it can cause paralysis from the neck down, whereas damage to the spinal column further down may limit paralysis to the legs. Spinal cord injuries are notoriously difficult to treat because spinal nerves do not regenerate, although ongoing research suggests that stem cell transplants may be able to act as a bridge to reconnect severed nerves. Researchers are also looking at ways to prevent the inflammation that worsens nerve damage after injury. One such treatment is to pump the body with cold saline to induce hypothermia. This cooling can prevent swelling and other processes that are thought to worsen spinal cord injuries.

**Figure 26.25** A cross-section of the spinal cord shows gray matter (containing cell bodies and interneurons) and white matter (containing axons).

## 26.4 | The Peripheral Nervous System

In this section, you will explore the following questions:

- What are the organization and functions of the sympathetic and parasympathetic nervous systems?
- What is the organization and function of the sensory-somatic nervous system?

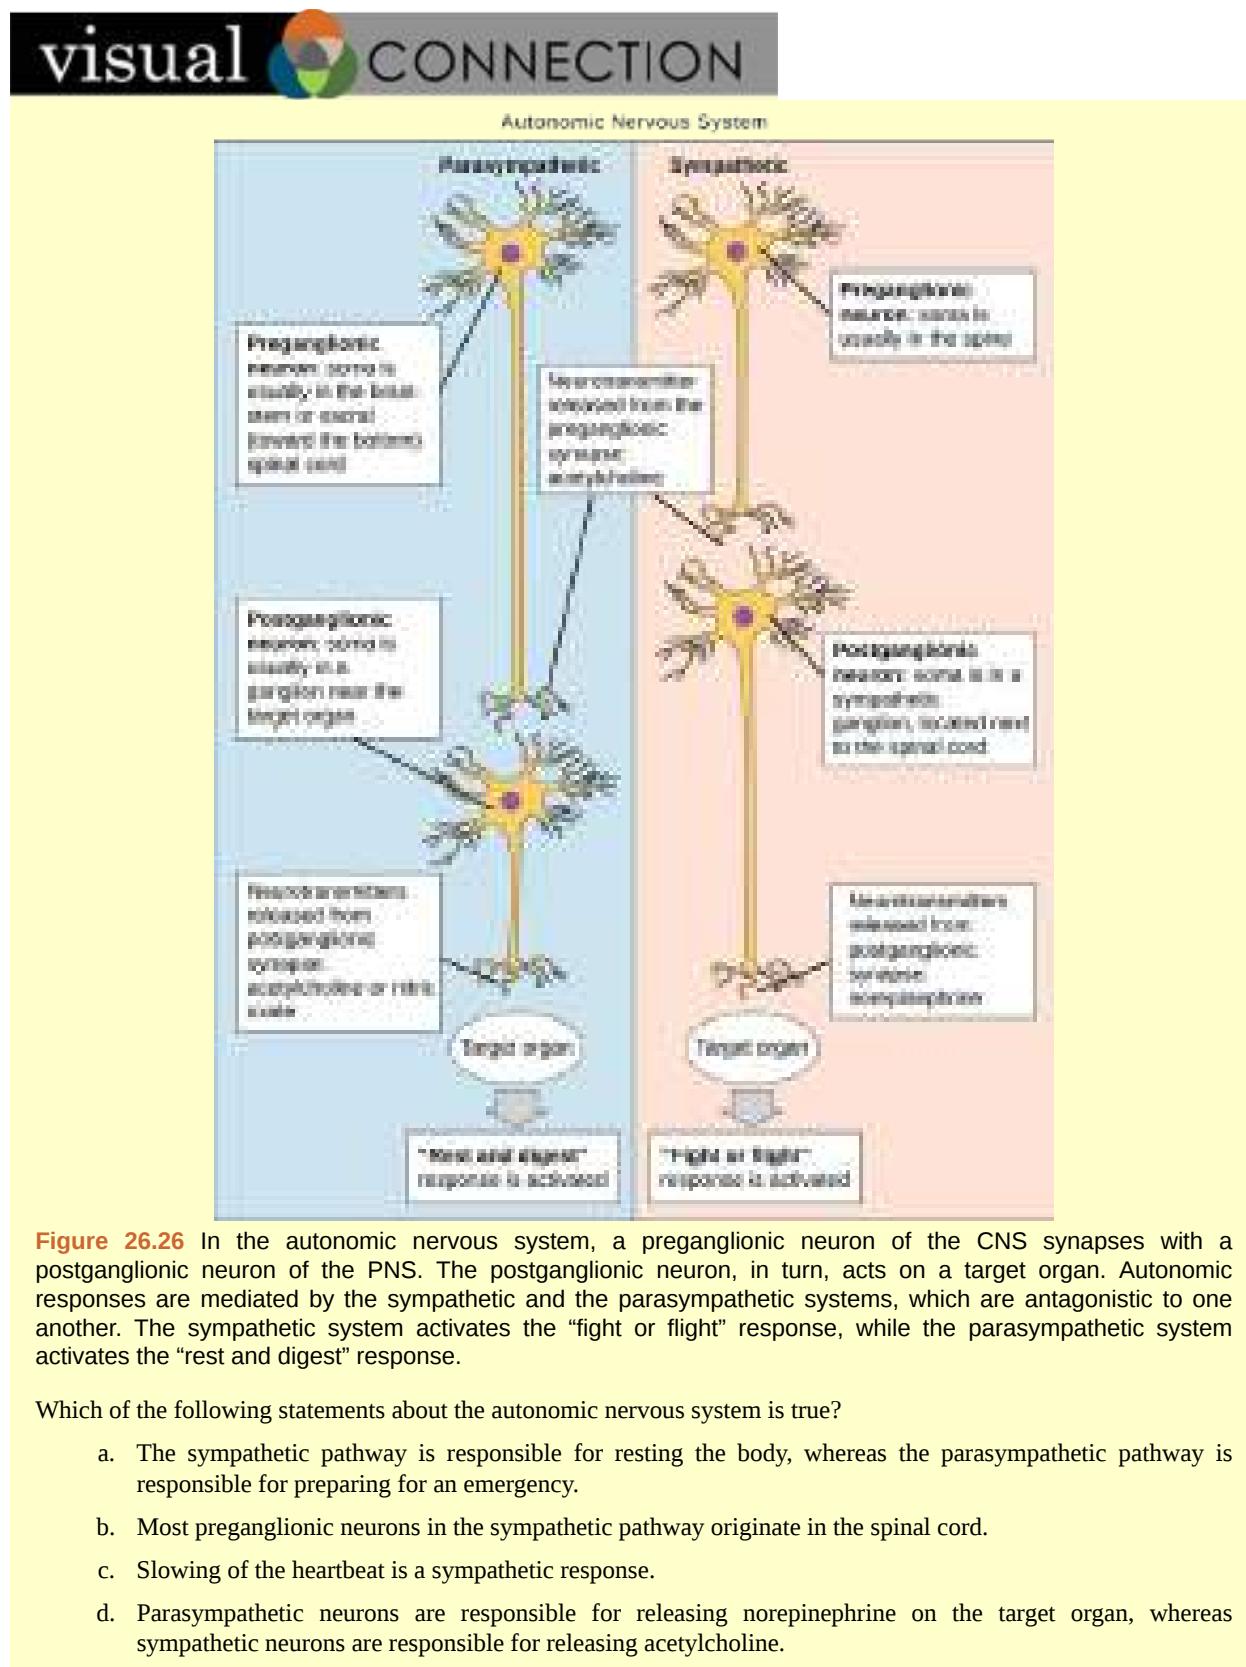

### Connection for AP® Courses

The information about the peripheral nervous system is not within the scope of AP®. However, it is important to note that the peripheral nervous system (PNS) is the connection between the central nervous system and the rest of the body. The PNS can be broken down into the autonomic nervous system, which controls bodily functions without conscious control, and the sensory-somatic nervous system, which transmits sensory information from the skin, muscles, and sensory organs to the CNS and motor commands from the CNS to the muscles. The autonomic nervous system can be further divided into the parasympathetic and sympathetic pathways. “Rest and digest” responses are activated by the parasympathetic division, whereas “fight or flight” responses are activated by the sympathetic division. In other words, these two systems often have opposing effects on target organs; for example, activation of the parasympathetic system slows heart rate, whereas activation of the sympathetic system increases heart rate. (If, as you’re reading this information, a *Tyrannosaurus rex* barged into the room, which division would be activated?) The sensory-somatic nervous system is made up of cranial and spinal nerves with both sensory and motor neurons.

The peripheral nervous system (PNS) is the connection between the central nervous system and the rest of the body. The CNS is like the power plant of the nervous system. It creates the signals that control the functions of the body. The PNS is like the wires that go to individual houses. Without those “wires,” the signals produced by the CNS could not control the body (and the CNS would not be able to receive sensory information from the body either).

The PNS can be broken down into the **autonomic nervous system**, which controls bodily functions without conscious control, and the **sensory-somatic nervous system**, which transmits sensory information from the skin, muscles, and sensory organs to the CNS and sends motor commands from the CNS to the muscles.

## Autonomic Nervous System

**Figure 26.26** In the autonomic nervous system, a preganglionic neuron of the CNS synapses with a postganglionic neuron of the PNS. The postganglionic neuron, in turn, acts on a target organ. Autonomic responses are mediated by the sympathetic and the parasympathetic systems, which are antagonistic to one another. The sympathetic system activates the “fight or flight” response, while the parasympathetic system activates the “rest and digest” response.

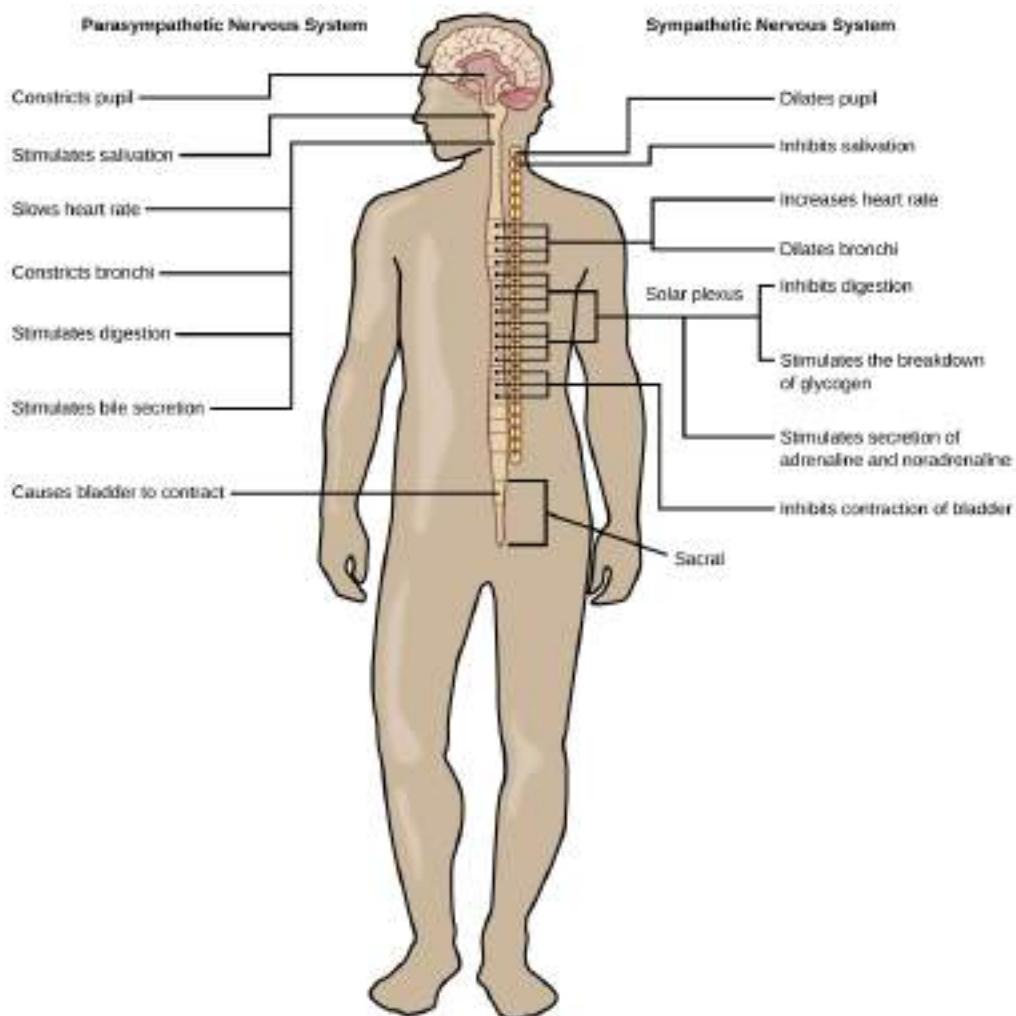

Which of the following statements about the autonomic nervous system is true?

- The sympathetic pathway is responsible for resting the body, whereas the parasympathetic pathway is responsible for preparing for an emergency.
- Most preganglionic neurons in the sympathetic pathway originate in the spinal cord.
- Slowing of the heartbeat is a sympathetic response.
- Parasympathetic neurons are responsible for releasing norepinephrine on the target organ, whereas sympathetic neurons are responsible for releasing acetylcholine.

The autonomic nervous system serves as the relay between the CNS and the internal organs. It controls the lungs, the heart, smooth muscle, and exocrine and endocrine glands. The autonomic nervous system controls these organs largely without conscious control; it can continuously monitor the conditions of these different systems and implement changes as needed. Signaling to the target tissue usually involves two synapses: a preganglionic neuron (originating in the CNS) synapses to a neuron in a ganglion that, in turn, synapses on the target organ, as illustrated in [Figure 26.26](#). There are two divisions of the autonomic nervous system that often have opposing effects: the sympathetic nervous system and the parasympathetic nervous system.

### Sympathetic Nervous System

The **sympathetic nervous system** is responsible for the “fight or flight” response that occurs when an animal encounters a dangerous situation. One way to remember this is to think of the surprise a person feels when encountering a snake (“snake” and “sympathetic” both begin with “s”). Examples of functions controlled by the sympathetic nervous system include an accelerated heart rate and inhibited digestion. These functions help prepare an organism’s body for the physical strain required to escape a potentially dangerous situation or to fend off a predator.

**Figure 26.27** The sympathetic and parasympathetic nervous systems often have opposing effects on target organs.

Most preganglionic neurons in the sympathetic nervous system originate in the spinal cord, as illustrated in [Figure 26.27](#). The axons of these neurons release **acetylcholine** on postganglionic neurons within sympathetic ganglia (the sympathetic ganglia form a chain that extends alongside the spinal cord). The acetylcholine activates the postganglionic neurons. Postganglionic neurons then release **norepinephrine** onto target organs. As anyone who has ever felt a rush before a big test, speech, or athletic event can attest, the effects of the sympathetic nervous system are quite pervasive. This is both because one preganglionic neuron synapses on multiple postganglionic neurons, amplifying the effect of the original synapse, and because the adrenal gland also releases norepinephrine (and the closely related hormone epinephrine) into the blood stream. The physiological effects of this norepinephrine release include dilating the trachea and bronchi (making it easier for the animal to breathe), increasing heart rate, and moving blood from the skin to the heart, muscles, and brain (so

the animal can think and run). The strength and speed of the sympathetic response helps an organism avoid danger, and scientists have found evidence that it may also increase LTP—allowing the animal to remember the dangerous situation and avoid it in the future.

### Parasympathetic Nervous System

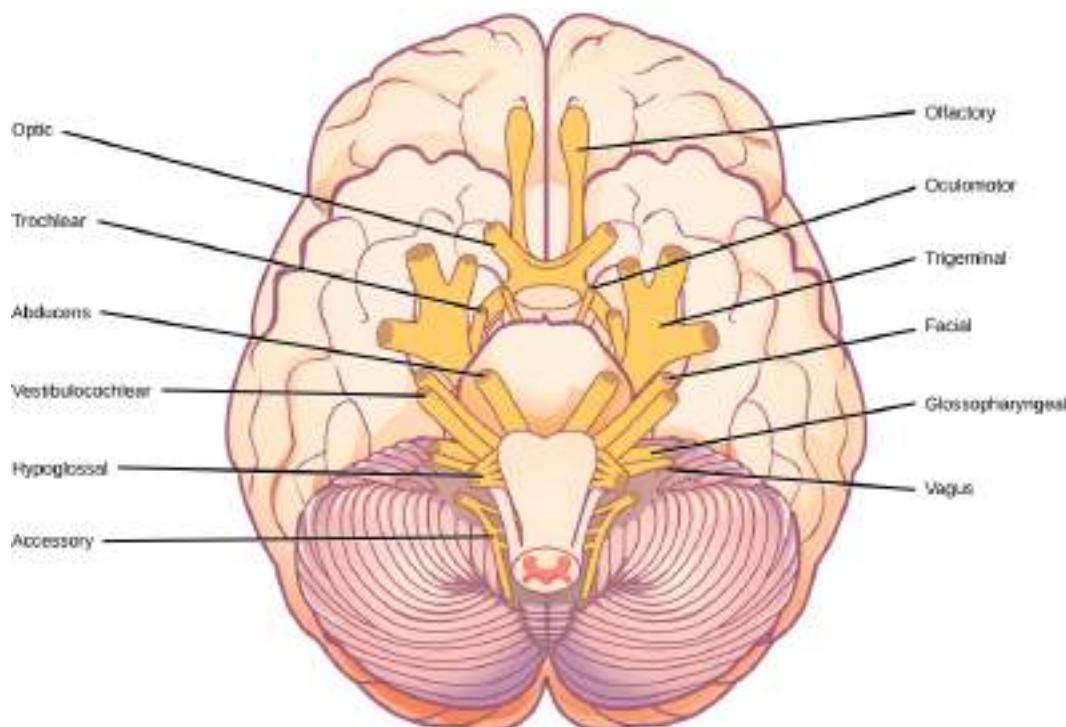

While the sympathetic nervous system is activated in stressful situations, the **parasympathetic nervous system** allows an animal to “rest and digest.” One way to remember this is to think that during a restful situation like a picnic, the parasympathetic nervous system is in control (“picnic” and “parasympathetic” both start with “p”). Parasympathetic preganglionic neurons have cell bodies located in the brainstem and in the sacral (toward the bottom) spinal cord, as shown in [Figure 26.27](#). The axons of the preganglionic neurons release acetylcholine on the postganglionic neurons, which are generally located very near the target organs. Most postganglionic neurons release acetylcholine onto target organs, although some release nitric oxide.

The parasympathetic nervous system resets organ function after the sympathetic nervous system is activated (the common adrenaline dump you feel after a ‘fight-or-flight’ event). Effects of acetylcholine release on target organs include slowing of heart rate, lowered blood pressure, and stimulation of digestion.

## Sensory-Somatic Nervous System

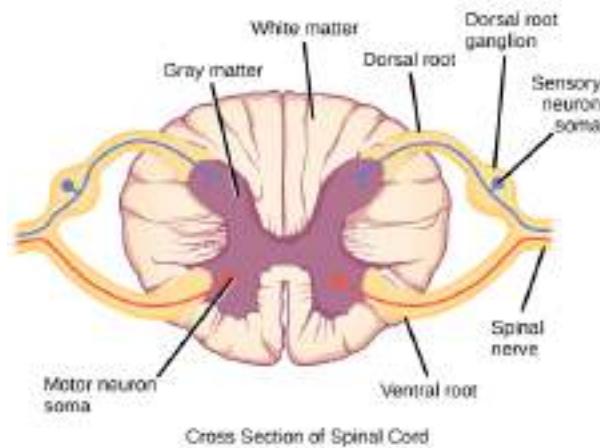

The sensory-somatic nervous system is made up of cranial and spinal nerves and contains both sensory and motor neurons. Sensory neurons transmit sensory information from the skin, skeletal muscle, and sensory organs to the CNS. Motor neurons transmit messages about desired movement from the CNS to the muscles to make them contract. Without its sensory-somatic nervous system, an animal would be unable to process any information about its environment (what it sees, feels, hears, and so on) and could not control motor movements. Unlike the autonomic nervous system, which has two synapses between the CNS and the target organ, sensory and motor neurons have only one synapse—one ending of the neuron is at the organ and the other directly contacts a CNS neuron. Acetylcholine is the main neurotransmitter released at these synapses.

Humans have 12 **cranial nerves**, nerves that emerge from or enter the skull (cranium), as opposed to the spinal nerves, which emerge from the vertebral column. Each cranial nerve is accorded a name, which are detailed in [Figure 26.28](#). Some cranial nerves transmit only sensory information. For example, the olfactory nerve transmits information about smells from the nose to the brainstem. Other cranial nerves transmit almost solely motor information. For example, the oculomotor nerve controls the opening and closing of the eyelid and some eye movements. Other cranial nerves contain a mix of sensory and motor fibers. For example, the glossopharyngeal nerve has a role in both taste (sensory) and swallowing (motor).

**Figure 26.28** The human brain contains 12 cranial nerves that receive sensory input and control motor output for the head and neck.

**Spinal nerves** transmit sensory and motor information between the spinal cord and the rest of the body. Each of the 31 spinal nerves (in humans) contains both sensory and motor axons. The sensory neuron cell bodies are grouped in structures called dorsal root ganglia and are shown in **Figure 26.29**. Each sensory neuron has one projection—with a sensory receptor ending in skin, muscle, or sensory organs—and another that synapses with a neuron in the dorsal spinal cord. Motor neurons have cell bodies in the ventral gray matter of the spinal cord that project to muscle through the ventral root. These neurons are usually stimulated by interneurons within the spinal cord but are sometimes directly stimulated by sensory neurons.

**Figure 26.29** Spinal nerves contain both sensory and motor axons. The somas of sensory neurons are located in dorsal root ganglia. The somas of motor neurons are found in the ventral portion of the gray matter of the spinal cord.

## 26.5 | Nervous System Disorders

In this section, you will explore the following questions:

- What are examples of symptoms, causes, and treatments for several examples of nervous system disorders?

### Connection for AP® Courses

Information about disorders of the nervous system is out of scope for AP®. A nervous system that functions correctly is a complex and well-oiled machine—synapses fire appropriately, muscle move when needed, memories are formed and stored, and emotions are well regulated. You can now appreciate what it takes for you to be able to read and comprehend the information in this textbook. Unfortunately, each year millions of people in the United States deal with some sort of disorder involving the nervous system. Neurodegenerative disorders are characterized by loss of nervous system functioning usually caused by the death of neurons; examples include Alzheimer’s disease, Parkinson’s disease, and amyotrophic lateral sclerosis (ALS). Neurodevelopmental disorders occur when the development of the nervous system is disturbed; examples include autism spectrum disorder (ASD), attention deficit hyperactivity disorder (ADHD), schizophrenia, and major depression. Epilepsy and stroke also have neurological origins. Although scientists have discovered potential causes of many of these diseases, and effective treatments for some, ongoing research into the prevention and treatment of these disorders continues.

A nervous system that functions correctly is a fantastically complex, well-oiled machine—synapses fire appropriately, muscles move when needed, memories are formed and stored, and emotions are well regulated. Unfortunately, each year millions of people in the United States deal with some sort of nervous system disorder. While scientists have discovered potential causes of many of these diseases, and viable treatments for some, ongoing research seeks to find ways to better prevent and treat all of these disorders.

### Neurodegenerative Disorders

**Neurodegenerative disorders** are illnesses characterized by a loss of nervous system functioning that are usually caused by neuronal death. These diseases generally worsen over time as more and more neurons die. The symptoms of a particular neurodegenerative disease are related to where in the nervous system the death of neurons occurs. Spinocerebellar ataxia, for example, leads to neuronal death in the cerebellum. The death of these neurons causes problems in balance and walking. Neurodegenerative disorders include Huntington’s disease, amyotrophic lateral sclerosis, Alzheimer’s disease and other types of dementia disorders, and Parkinson’s disease. Here, Alzheimer’s and Parkinson’s disease will be discussed in more depth.

#### Alzheimer’s Disease

**Alzheimer’s disease** is the most common cause of dementia in the elderly. In 2012, an estimated 5.4 million Americans suffered from Alzheimer’s disease, and payments for their care are estimated at \$200 billion. Roughly one in every eight people age 65 or older has the disease. Due to the aging of the baby-boomer generation, there are projected to be as many as 13 million Alzheimer’s patients in the United States in the year 2050.

Symptoms of Alzheimer’s disease include disruptive memory loss, confusion about time or place, difficulty planning or executing tasks, poor judgment, and personality changes. Problems smelling certain scents can also be indicative of Alzheimer’s disease and may serve as an early warning sign. Many of these symptoms are also common in people who are aging normally, so it is the severity and longevity of the symptoms that determine whether a person is suffering from Alzheimer’s.

Alzheimer’s disease was named for Alois Alzheimer, a German psychiatrist who published a report in 1911 about a woman who showed severe dementia symptoms. Along with his colleagues, he examined the woman’s brain following her death and reported the presence of abnormal clumps, which are now called amyloid plaques, along with tangled brain fibers called neurofibrillary tangles. Amyloid plaques, neurofibrillary tangles, and an overall shrinking of brain volume are commonly seen in the brains of Alzheimer’s patients. Loss of neurons in the hippocampus is especially severe in advanced Alzheimer’s patients. **Figure 26.30** compares a normal brain to the brain of an Alzheimer’s patient. Many research groups are examining the causes of these hallmarks of the disease.

One form of the disease is usually caused by mutations in one of three known genes. This rare form of early onset Alzheimer’s disease affects fewer than five percent of patients with the disease and causes dementia beginning between the ages of 30 and 60. The more prevalent, late-onset form of the disease likely also has a genetic component. One particular

gene, apolipoprotein E (APOE) has a variant (E4) that increases a carrier's likelihood of getting the disease. Many other genes have been identified that might be involved in the pathology.

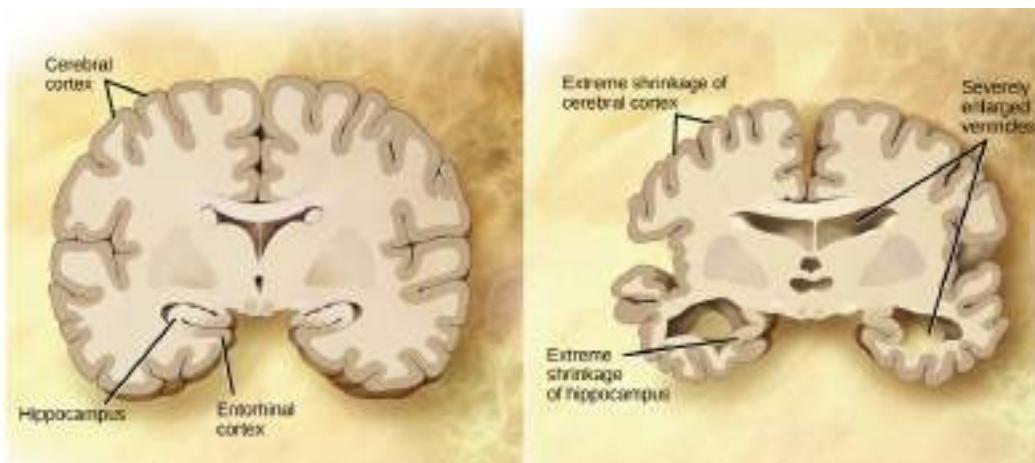

Visit [this website](http://openstaxcollege.org/l/alzheimers) (<http://openstaxcollege.org/l/alzheimers>) for video links discussing genetics and Alzheimer's disease.

What statement about risk genes in Alzheimer's disease is true?

- a. Risk genes do not guarantee that a person will get Alzheimer's disease.
- b. Risk genes account for <5% of Alzheimer's cases.
- c. Risk genes directly cause a disease.
- d. Individuals with risk genes have symptoms that develop when an individual is in their 40s or 50s.

Unfortunately, there is no cure for Alzheimer's disease. Current treatments focus on managing the symptoms of the disease. Because decrease in the activity of cholinergic neurons (neurons that use the neurotransmitter acetylcholine) is common in Alzheimer's disease, several drugs used to treat the disease work by increasing acetylcholine transmission, often by inhibiting the enzyme that breaks down acetylcholine in the synaptic cleft. Other clinical interventions focus on behavioral therapies like psychotherapy, sensory therapy, and cognitive exercises. Since Alzheimer's disease appears to hijack the normal aging process, research into prevention is prevalent. Smoking, obesity, and cardiovascular problems may be risk factors for the disease, so treatments for those may also help to prevent Alzheimer's disease. Some studies have shown that people who remain intellectually active by playing games, reading, playing musical instruments, and being socially active in later life have a reduced risk of developing the disease.

**Figure 26.30** Compared to a normal brain (left), the brain from a patient with Alzheimer's disease (right) shows a dramatic neurodegeneration, particularly within the ventricles and hippocampus. (credit: modification of work by "Garrando"/Wikimedia Commons based on original images by ADEAR: "Alzheimer's Disease Education and Referral Center, a service of the National Institute on Aging")

### Parkinson's Disease

Like Alzheimer's disease, **Parkinson's disease** is a neurodegenerative disease. It was first characterized by James Parkinson in 1817. Each year, 50,000-60,000 people in the United States are diagnosed with the disease. Parkinson's disease causes the loss of dopamine neurons in the substantia nigra, a midbrain structure that regulates movement. Loss of these neurons causes many symptoms including tremor (shaking of fingers or a limb), slowed movement, speech changes, balance and posture problems, and rigid muscles. The combination of these symptoms often causes a characteristic slow hunched

shuffling walk, illustrated in **Figure 26.31**. Patients with Parkinson's disease can also exhibit psychological symptoms, such as dementia or emotional problems.

Although some patients have a form of the disease known to be caused by a single mutation, for most patients the exact causes of Parkinson's disease remain unknown: the disease likely results from a combination of genetic and environmental factors (similar to Alzheimer's disease). Post-mortem analysis of brains from Parkinson's patients shows the presence of Lewy bodies—abnormal protein clumps—in dopaminergic neurons. The prevalence of these Lewy bodies often correlates with the severity of the disease.

There is no cure for Parkinson's disease, and treatment is focused on easing symptoms. One of the most commonly prescribed drugs for Parkinson's is L-DOPA, which is a chemical that is converted into dopamine by neurons in the brain. This conversion increases the overall level of dopamine neurotransmission and can help compensate for the loss of dopaminergic neurons in the substantia nigra. Other drugs work by inhibiting the enzyme that breaks down dopamine.

**Figure 26.31** Parkinson's patients often have a characteristic hunched walk.

## everyday CONNECTION for AP® Courses

**Figure 26.32** Amyotrophic lateral sclerosis, also known as ALS or Lou Gehrig's disease, is a rapidly progressing disease that attacks the neurons that control voluntary muscles. Stephen Hawking, one of the greatest scientists in modern times, suffers from ALS. Credit: 2<sup>o</sup>1<sup>oo</sup>

The roots of the term amyotrophic lateral sclerosis (ALS) provide clues as to what happens to an individual with this disease. “Amyotrophic” means “no muscle nourishment,” “lateral” refers to the part of the spine that tells muscles what to do, and “sclerosis” indicates that the lateral portion of the spine that controls muscle movement hardens. Explain how ALS causes a decline in voluntary muscle control over time.

- ALS degenerates sensory neurons that control voluntary muscle movement. As the lateral portion of the spine that controls muscle movement hardens, signals are no longer sent to muscles. Initially, muscles weaken but coordination is not effected, and eventually paralysis occurs.
- ALS degenerates motor neurons that control voluntary muscle movement. As the lateral portion of the spine that controls muscle movement hardens, signals are no longer sent to muscles. Initially, muscles strengthen and coordination is effected, and eventually paralysis occurs.
- ALS degenerates sensory neurons that control voluntary muscle movement. As the lateral portion of the spine that controls muscle movement hardens, signals are no longer sent to muscles. Initially, muscles weaken and coordination is effected, and eventually paralysis occurs.
- ALS degenerates motor neurons that control voluntary muscle movement. As the lateral portion of the spine that controls muscle movement hardens, signals are no longer sent to muscles. Initially, muscles weaken and coordination is effected, and eventually paralysis occurs.

## Neurodevelopmental Disorders

Neurodevelopmental disorders occur when the development of the nervous system is disturbed. There are several different classes of neurodevelopmental disorders. Some, like Down Syndrome, cause intellectual deficits. Others specifically affect communication, learning, or the motor system. Some disorders like autism spectrum disorder and attention deficit/hyperactivity disorder have complex symptoms.

### Autism

**Autism spectrum disorder (ASD)** is a neurodevelopmental disorder. Its severity differs from person to person. Estimates for the prevalence of the disorder have changed rapidly in the past few decades. Current estimates suggest that one in 88 children will develop the disorder. ASD is four times more prevalent in males than females.

This video (<http://openstaxcollege.org/l/autism>) discusses possible reasons why there has been a recent increase in the number of people diagnosed with autism.

Which of the following is a partial explanation of the increase in autism spectrum disorder diagnosis between 1992 and 2005?

- a. diagnostic criteria changed
- b. increased vaccination rates
- c. more young parents reproducing
- d. decreased ascertainment across classes

A characteristic symptom of ASD is impaired social skills. Children with autism may have difficulty making and maintaining eye contact and reading social cues. They also may have problems feeling empathy for others. Other symptoms of ASD include repetitive motor behaviors (such as rocking back and forth), preoccupation with specific subjects, strict adherence to certain rituals, and unusual language use. Up to 30 percent of patients with ASD develop epilepsy, and patients with some forms of the disorder (like Fragile X) also have intellectual disability. Because it is a spectrum disorder, other ASD patients are very functional and have good-to-excellent language skills. Many of these patients do not feel that they suffer from a disorder and instead think that their brains just process information differently.

Except for some well-characterized, clearly genetic forms of autism (like Fragile X and Rett's Syndrome), the causes of ASD are largely unknown. Variants of several genes correlate with the presence of ASD, but for any given patient, many different mutations in different genes may be required for the disease to develop. At a general level, ASD is thought to be a disease of “incorrect” wiring. Accordingly, brains of some ASD patients lack the same level of synaptic pruning that occurs in non-affected people. In the 1990s, a research paper linked autism to a common vaccine given to children. This paper was retracted when it was discovered that the author falsified data, and follow-up studies showed no connection between vaccines and autism.

Treatment for autism usually combines behavioral therapies and interventions, along with medications to treat other disorders common to people with autism (depression, anxiety, obsessive compulsive disorder). Although early interventions can help mitigate the effects of the disease, there is currently no cure for ASD.

### Attention Deficit Hyperactivity Disorder (ADHD)

Approximately three to five percent of children and adults are affected by **attention deficit/hyperactivity disorder (ADHD)**. Like ASD, ADHD is more prevalent in males than females. Symptoms of the disorder include inattention (lack of focus), executive functioning difficulties, impulsivity, and hyperactivity beyond what is characteristic of the normal developmental stage. Some patients do not have the hyperactive component of symptoms and are diagnosed with a subtype of ADHD: attention deficit disorder (ADD). Many people with ADHD also show comorbidity, in that they develop secondary disorders in addition to ADHD. Examples include depression or obsessive compulsive disorder (OCD). **Figure 26.33** provides some statistics concerning comorbidity with ADHD.

The cause of ADHD is unknown, although research points to a delay and dysfunction in the development of the prefrontal cortex and disturbances in neurotransmission. According to studies of twins, the disorder has a strong genetic component. There are several candidate genes that may contribute to the disorder, but no definitive links have been discovered. Environmental factors, including exposure to certain pesticides, may also contribute to the development of ADHD in some

patients. Treatment for ADHD often involves behavioral therapies and the prescription of stimulant medications, which paradoxically cause a calming effect in these patients.

**Figure 26.33** Many people with ADHD have one or more other neurological disorders. (credit “chart design and illustration”: modification of work by Leigh Coriale; credit “data”: Drs. Biederman and Faraone, Massachusetts General Hospital).

## Career CONNECTION

### Neurologist

Neurologists are physicians who specialize in disorders of the nervous system. They diagnose and treat disorders such as epilepsy, stroke, dementia, nervous system injuries, Parkinson’s disease, sleep disorders, and multiple sclerosis. Neurologists are medical doctors who have attended college, medical school, and completed three to four years of neurology residency.

When examining a new patient, a neurologist takes a full medical history and performs a complete physical exam. The physical exam contains specific tasks that are used to determine what areas of the brain, spinal cord, or peripheral nervous system may be damaged. For example, to check whether the hypoglossal nerve is functioning correctly, the neurologist will ask the patient to move his or her tongue in different ways. If the patient does not have full control over tongue movements, then the hypoglossal nerve may be damaged or there may be a lesion in the brainstem where the cell bodies of these neurons reside (or there could be damage to the tongue muscle itself).

Neurologists have other tools besides a physical exam they can use to diagnose particular problems in the nervous system. If the patient has had a seizure, for example, the neurologist can use electroencephalography (EEG), which involves taping electrodes to the scalp to record brain activity, to try to determine which brain regions are involved in the seizure. In suspected stroke patients, a neurologist can use a computerized tomography (CT) scan, which is a type of X-ray, to look for bleeding in the brain or other health conditions. To treat patients with neurological problems, neurologists can prescribe medications or refer the patient to a neurosurgeon for surgery.

This website ([http://openstaxcollege.org/l/neurologic\\_exam](http://openstaxcollege.org/l/neurologic_exam)) allows you to see the different tests a neurologist might use to see what regions of the nervous system may be damaged in a patient.

What exam might a neurologist perform if a patient had impaired sensory functions?

- a. placing a 128 Hz tuning fork over a bone
- b. tapping a muscle tendon with a reflex hammer
- c. asking a patient to follow commands
- d. asking a patient to follow a target through different positions

### **Mental Illnesses**

Mental illnesses are nervous system disorders that result in problems with thinking, mood, or relating with other people. These disorders are severe enough to affect a person's quality of life and often make it difficult for people to perform the routine tasks of daily living. Debilitating mental disorders plague approximately 12.5 million Americans (about 1 in 17 people) at an annual cost of more than \$300 billion. There are several types of mental disorders including schizophrenia, major depression, bipolar disorder, anxiety disorders and phobias, post-traumatic stress disorders, and obsessive-compulsive disorder (OCD), among others. The American Psychiatric Association publishes the Diagnostic and Statistical Manual of Mental Disorders (or DSM), which describes the symptoms required for a patient to be diagnosed with a particular mental disorder. Each newly released version of the DSM contains different symptoms and classifications as scientists learn more about these disorders, their causes, and how they relate to each other. A more detailed discussion of two mental illnesses—schizophrenia and major depression—is given below.

#### **Schizophrenia**

**Schizophrenia** is a serious and often debilitating mental illness affecting one percent of people in the United States. Symptoms of the disease include the inability to differentiate between reality and imagination, inappropriate and unregulated emotional responses, difficulty thinking, and problems with social situations. People with schizophrenia can suffer from hallucinations and hear voices; they may also suffer from delusions. Patients also have so-called “negative” symptoms like a flattened emotional state, loss of pleasure, and loss of basic drives. Many schizophrenic patients are diagnosed in their late adolescence or early 20s. The development of schizophrenia is thought to involve malfunctioning dopaminergic neurons and may also involve problems with glutamate signaling. Treatment for the disease usually requires antipsychotic medications that work by blocking dopamine receptors and decreasing dopamine neurotransmission in the brain. This decrease in dopamine can cause Parkinson’s disease-like symptoms in some patients. While some classes of antipsychotics can be quite effective at treating the disease, they are not a cure, and most patients must remain medicated for the rest of their lives.

#### **Depression**

**Major depression** affects approximately 6.7 percent of the adults in the United States each year and is one of the most common mental disorders. To be diagnosed with major depressive disorder, a person must have experienced a severely depressed mood lasting longer than two weeks along with other symptoms including a loss of enjoyment in activities that were previously enjoyed, changes in appetite and sleep schedules, difficulty concentrating, feelings of worthlessness, and suicidal thoughts. The exact causes of major depression are unknown and likely include both genetic and environmental risk factors. Some research supports the “classic monoamine hypothesis,” which suggests that depression is caused by a decrease in norepinephrine and serotonin neurotransmission. One argument against this hypothesis is the fact that some antidepressant medications cause an increase in norepinephrine and serotonin release within a few hours of beginning treatment—but clinical results of these medications are not seen until weeks later. This has led to alternative hypotheses: for example, dopamine may also be decreased in depressed patients, or it may actually be an increase in norepinephrine and serotonin that causes the disease, and antidepressants force a feedback loop that decreases this release. Treatments for

depression include psychotherapy, electroconvulsive therapy, deep-brain stimulation, and prescription medications. There are several classes of antidepressant medications that work through different mechanisms. For example, monoamine oxidase inhibitors (MAO inhibitors) block the enzyme that degrades many neurotransmitters (including dopamine, serotonin, norepinephrine), resulting in increased neurotransmitter in the synaptic cleft. Selective serotonin reuptake inhibitors (SSRIs) block the reuptake of serotonin into the presynaptic neuron. This blockage results in an increase in serotonin in the synaptic cleft. Other types of drugs such as norepinephrine-dopamine reuptake inhibitors and norepinephrine-serotonin reuptake inhibitors are also used to treat depression.

## Other Neurological Disorders

There are several other neurological disorders that cannot be easily placed in the above categories. These include chronic pain conditions, cancers of the nervous system, epilepsy disorders, and stroke. Epilepsy and stroke are discussed below.

### Epilepsy

Estimates suggest that up to three percent of people in the United States will be diagnosed with **epilepsy** in their lifetime. While there are several different types of epilepsy, all are characterized by recurrent seizures. Epilepsy itself can be a symptom of a brain injury, disease, or other illness. For example, people who have intellectual disability or ASD can experience seizures, presumably because the developmental wiring malfunctions that caused their disorders also put them at risk for epilepsy. For many patients, however, the cause of their epilepsy is never identified and is likely to be a combination of genetic and environmental factors. Often, seizures can be controlled with anticonvulsant medications. However, for very severe cases, patients may undergo brain surgery to remove the brain area where seizures originate.

### Stroke

A stroke results when blood fails to reach a portion of the brain for a long enough time to cause damage. Without the oxygen supplied by blood flow, neurons in this brain region die. This neuronal death can cause many different symptoms—depending on the brain area affected—including headache, muscle weakness or paralysis, speech disturbances, sensory problems, memory loss, and confusion. Stroke is often caused by blood clots and can also be caused by the bursting of a weak blood vessel. Strokes are extremely common and are the third most common cause of death in the United States. On average one person experiences a stroke every 40 seconds in the United States. Approximately 75 percent of strokes occur in people older than 65. Risk factors for stroke include high blood pressure, diabetes, high cholesterol, and a family history of stroke. Because a stroke is a medical emergency, patients with symptoms of a stroke should immediately go to the emergency room, where they can receive drugs that will dissolve any clot that may have formed. These drugs will not work if the stroke was caused by a burst blood vessel or if the stroke occurred more than three hours before arriving at the hospital. Treatment following a stroke can include blood pressure medication (to prevent future strokes) and (sometimes intense) physical therapy.

## KEY TERMS

**acetylcholine** neurotransmitter released by neurons in the central nervous system and peripheral nervous system

**action potential** self-propagating momentary change in the electrical potential of a neuron (or muscle) membrane

**Alzheimer's disease** neurodegenerative disorder characterized by problems with memory and thinking

**amygdala** structure within the limbic system that processes fear

**arachnoid mater** spiderweb-like middle layer of the meninges that cover the central nervous system

**astrocyte** glial cell in the central nervous system that provide nutrients, extracellular buffering, and structural support for neurons; also makes up the blood-brain barrier

**attention deficit hyperactivity disorder (ADHD)** neurodevelopmental disorder characterized by difficulty maintaining attention and controlling impulses

**autism spectrum disorder (ASD)** neurodevelopmental disorder characterized by impaired social interaction and communication abilities

**autonomic nervous system** part of the peripheral nervous system that controls bodily functions

**axon** tube-like structure that propagates a signal from a neuron's cell body to axon terminals

**axon hillock** electrically sensitive structure on the cell body of a neuron that integrates signals from multiple neuronal connections

**axon terminal** structure on the end of an axon that can form a synapse with another neuron

**basal ganglia** interconnected collections of cells in the brain that are involved in movement and motivation; also known as basal nuclei

**basal nuclei** see basal ganglia

**brainstem** portion of the brain that connects with the spinal cord; controls basic nervous system functions like breathing, heart rate, and swallowing

**cerebellum** brain structure involved in posture, motor coordination, and learning new motor actions

**cerebral cortex** outermost sheet of brain tissue; involved in many higher-order functions

**cerebrospinal fluid (CSF)** clear liquid that surrounds the brain and spinal cord and fills the ventricles and central canal; acts as a shock absorber and circulates material throughout the brain and spinal cord.

**choroid plexus** spongy tissue within ventricles that produces cerebrospinal fluid

**cingulate gyrus** helps regulate emotions and pain; thought to directly drive the body's conscious response to unpleasant experiences

**corpus callosum** thick fiber bundle that connects the cerebral hemispheres

**cranial nerve** sensory and/or motor nerve that emanates from the brain

**dendrite** structure that extends away from the cell body to receive messages from other neurons

**depolarization** change in the membrane potential to a less negative value

**dura mater** tough outermost layer that covers the central nervous system

**ependymal** cell that lines fluid-filled ventricles of the brain and the central canal of the spinal cord; involved in production of cerebrospinal fluid

**epilepsy** neurological disorder characterized by recurrent seizures

**excitatory postsynaptic potential (EPSP)** depolarization of a postsynaptic membrane caused by neurotransmitter molecules released from a presynaptic cell

**frontal lobe** part of the cerebral cortex that contains the motor cortex and areas involved in planning, attention, and language

**glia** (also, glial cells) cells that provide support functions for neurons

**gyrus** (plural: gyri) ridged protrusions in the cortex

**hippocampus** brain structure in the temporal lobe involved in processing memories

**hyperpolarization** change in the membrane potential to a more negative value

**hypothalamus** brain structure that controls hormone release and body homeostasis

**inhibitory postsynaptic potential (IPSP)** hyperpolarization of a postsynaptic membrane caused by neurotransmitter molecules released from a presynaptic cell

**limbic system** connected brain areas that process emotion and motivation

**long-term depression (LTD)** prolonged decrease in synaptic coupling between a pre- and postsynaptic cell

**long-term potentiation (LTP)** prolonged increase in synaptic coupling between a pre-and postsynaptic cell

**major depression** mental illness characterized by prolonged periods of sadness

**membrane potential** difference in electrical potential between the inside and outside of a cell

**meninge** membrane that covers and protects the central nervous system

**microglia** glia that scavenge and degrade dead cells and protect the brain from invading microorganisms

**myelin** fatty substance produced by glia that insulates axons

**neurodegenerative disorder** nervous system disorder characterized by the progressive loss of neurological functioning, usually caused by neuron death

**neuron** specialized cell that can receive and transmit electrical and chemical signals

**nodes of Ranvier** gaps in the myelin sheath where the signal is recharged

**norepinephrine** neurotransmitter and hormone released by activation of the sympathetic nervous system

**occipital lobe** part of the cerebral cortex that contains visual cortex and processes visual stimuli

**oligodendrocyte** glial cell that myelinates central nervous system neuron axons

**parasympathetic nervous system** division of autonomic nervous system that regulates visceral functions during rest and digestion

**parietal lobe** part of the cerebral cortex involved in processing touch and the sense of the body in space

**Parkinson's disease** neurodegenerative disorder that affects the control of movement

**pia mater** thin membrane layer directly covering the brain and spinal cord

**proprioception** sense about how parts of the body are oriented in space

**radial glia** glia that serve as scaffolds for developing neurons as they migrate to their final destinations

**refractory period** period after an action potential when it is more difficult or impossible for an action potential to be

- fired; caused by inactivation of sodium channels and activation of additional potassium channels of the membrane
- saltatory conduction** “jumping” of an action potential along an axon from one node of Ranvier to the next
- satellite glia** glial cell that provides nutrients and structural support for neurons in the peripheral nervous system
- schizophrenia** mental disorder characterized by the inability to accurately perceive reality; patients often have difficulty thinking clearly and can suffer from delusions
- Schwann cell** glial cell that creates myelin sheath around a peripheral nervous system neuron axon
- sensory-somatic nervous system** system of sensory and motor nerves
- somatosensation** sense of touch
- spinal cord** thick fiber bundle that connects the brain with peripheral nerves; transmits sensory and motor information; contains neurons that control motor reflexes
- spinal nerve** nerve projecting between skin or muscle and spinal cord
- sulcus** (plural: sulci) indents or “valleys” in the cortex
- summation** process of multiple presynaptic inputs creating EPSPs around the same time for the postsynaptic neuron to be sufficiently depolarized to fire an action potential
- sympathetic nervous system** division of autonomic nervous system activated during stressful “fight or flight” situations
- synapse** junction between two neurons where neuronal signals are communicated
- synaptic cleft** space between the presynaptic and postsynaptic membranes
- synaptic vesicle** spherical structure that contains a neurotransmitter
- temporal lobe** part of the cerebral cortex that processes auditory input; parts of the temporal lobe are involved in speech, memory, and emotion processing
- thalamus** brain area that relays sensory information to the cortex
- threshold of excitation** level of depolarization needed for an action potential to fire
- ventricle** cavity within brain that contains cerebrospinal fluid

## CHAPTER SUMMARY

### 26.1 Neurons and Glial Cells

The nervous system is made up of neurons and glia. Neurons are specialized cells that are capable of sending electrical as well as chemical signals. Most neurons contain dendrites, which receive these signals, and axons that send signals to other neurons or tissues. There are four main types of neurons: unipolar, bipolar, multipolar, and pseudounipolar neurons. Glia are non-neuronal cells in the nervous system that support neuronal development and signaling. There are several types of glia that serve different functions.

### 26.2 How Neurons Communicate

Neurons have charged membranes because there are different concentrations of ions inside and outside of the cell. Voltage-gated ion channels control the movement of ions into and out of a neuron. When a neuronal membrane is depolarized to at least the threshold of excitation, an action potential is fired. The action potential is then propagated along a myelinated axon to the axon terminals. In a chemical synapse, the action potential causes release of neurotransmitter molecules into the synaptic cleft. Through binding to postsynaptic receptors, the neurotransmitter can cause excitatory or inhibitory postsynaptic potentials by depolarizing or hyperpolarizing, respectively, the postsynaptic membrane. In electrical synapses, the action potential is directly communicated to the postsynaptic cell through gap junctions—large channel

proteins that connect the pre-and postsynaptic membranes. Synapses are not static structures and can be strengthened and weakened. Two mechanisms of synaptic plasticity are long-term potentiation and long-term depression.

### 26.3 The Central Nervous System

The vertebrate central nervous system contains the brain and the spinal cord, which are covered and protected by three meninges. The brain contains structurally and functionally defined regions. In mammals, these include the cortex (which can be broken down into four primary functional lobes: frontal, temporal, occipital, and parietal), basal ganglia, thalamus, hypothalamus, limbic system, cerebellum, and brainstem—although structures in some of these designations overlap. While functions may be primarily localized to one structure in the brain, most complex functions, like language and sleep, involve neurons in multiple brain regions. The spinal cord is the information superhighway that connects the brain with the rest of the body through its connections with peripheral nerves. It transmits sensory and motor input and also controls motor reflexes.

### 26.4 The Peripheral Nervous System

The peripheral nervous system contains both the autonomic and sensory-somatic nervous systems. The autonomic nervous system provides unconscious control over visceral functions and has two divisions: the sympathetic and parasympathetic nervous systems. The sympathetic nervous system is activated in stressful situations to prepare the animal for a “fight or flight” response. The parasympathetic nervous system is active during restful periods. The sensory-somatic nervous system is made of cranial and spinal nerves that transmit sensory information from skin and muscle to the CNS and motor commands from the CNS to the muscles.

### 26.5 Nervous System Disorders

Some general themes emerge from the sampling of nervous system disorders presented above. The causes for most disorders are not fully understood—at least not for all patients—and likely involve a combination of nature (genetic mutations that become risk factors) and nurture (emotional trauma, stress, hazardous chemical exposure). Because the causes have yet to be fully determined, treatment options are often lacking and only address symptoms.

## REVIEW QUESTIONS

1. Where are parasympathetic preganglionic cell bodies located?
  - a. cerebellum
  - b. brainstem
  - c. dorsal root ganglia
  - d. spinal cord
2. Which of the following statements about the parasympathetic nervous system is true?
  - a. controls “fight or flight” response
  - b. can reset organ function to the normal range
  - c. transmits information from the skin to the central nervous system
  - d. stimulates glycogen breakdown
3. Proper nervous system function involves various types of organic molecules. In particular, what is released by motor nerve endings onto muscle cells or tissue?
  - a. acetylcholine
  - b. norepinephrine
  - c. dopamine
  - d. serotonin
4. If the sensory-somatic nervous system of an animal is damaged, what might happen?
  - a. enhanced processing of environmental information
  - b. decreased digestion ability
  - c. perpetually low heart rate
  - d. impaired control of motor movements
5. The nervous system regulates proper processing of information and behavior control. The parasympathetic and sympathetic nervous systems are part of the \_\_\_\_\_ nervous system.
  - a. autonomic
  - b. sensory-somatic
  - c. central
  - d. “fight or flight”
6. Medications can be used to treat certain neurodevelopmental disorders. For example, which medications are often used to treat patients with ADHD?
  - a. tranquilizers
  - b. blood pressure medications
  - c. stimulants
  - d. anti-convulsant medications

**7.** If a child appears to have impaired social skills, such as difficulty reading social cues or making eye contact, what might they be tested for?

- a. major depression
- b. attention deficit hyperactivity disorder (ADHD)
- c. schizophrenia
- d. autism spectrum disorder

**8.** Parkinson's disease is a neurodegenerative disease that

can produce symptoms such as tremors, slowed movement, speech changes, balance and posture problems, and rigid muscles. Parkinson's disease is caused by the degeneration of neurons that release \_\_\_\_.

- a. serotonin
- b. dopamine
- c. glutamate
- d. norepinephrine

## CRITICAL THINKING QUESTIONS

**9.** When you stick your hand in a bucket of ice, it grows numb after a while. Based on what you know regarding neuronal signaling, explain how the sensation of touch is blocked from signaling to the brain.

**10.** Lidocaine is a local anesthetic that works by blocking voltage-gated sodium channels. Explain how blocking voltage-gated sodium channels would cause numbness and pain.

**11.** What are the main differences between the sympathetic and parasympathetic nervous systems?

- a. The sympathetic nervous system is activated by stressful situations, whereas the parasympathetic nervous system resets organ function of sympathetic reactions and allows animals to "rest and digest."
- b. The parasympathetic nervous system is activated by stressful situations, whereas the sympathetic nervous system resets organ function of sympathetic reactions and allows animals to "rest and digest."
- c. The sympathetic nervous system is involved in unconscious body function control, whereas the parasympathetic nervous system is involved in conscious body function control.
- d. The parasympathetic nervous system is involved in unconscious body function control, whereas the sympathetic nervous system is involved in conscious body function control.

**12.** How is the sensory-somatic nervous system involved in sensing information and motor function?

**a.** The sensory-somatic nervous system transmits information from the skin, muscles, and sensory organs to the peripheral nervous system. Motor information is sent to and from the central nervous system and the muscles.

**b.** The sensory-somatic nervous system transmits information from the skin, muscles, and sensory organs to the central nervous system. Motor information is sent to and from the central nervous system and the muscles.

**c.** The sensory-somatic nervous system transmits information from the skin, muscles, and sensory organs to the central nervous system. Motor information is sent to and from the peripheral nervous system and the muscles.

**d.** The sensory-somatic nervous system transmits information from the skin, muscles, and sensory organs to the peripheral nervous system. Motor information is sent to and from the peripheral nervous system and the muscles.

**13.** Public speaking can be very stressful. How can anticipating giving a public speech stimulate the sympathetic nervous system?

- a. During stress, multiple preganglionic neurons can synapse on one postganglionic neuron, and the adrenal gland releases adrenaline.
- b. During stress, one preganglionic neuron can synapse on multiple postganglionic neurons, and the thymus gland releases norepinephrine.
- c. During stress, one postganglionic neuron can synapse on multiple preganglionic neurons, and the adrenal gland releases norepinephrine.
- d. During stress, one preganglionic neuron can synapse on multiple postganglionic neurons, and the adrenal gland releases norepinephrine.

**14.** What might make you suspect that an individual has Alzheimer's disease?

- a. disruptive memory loss, confusion about time or place, difficulty with planning and executing tasks, poor judgment, and/or personality changes
  - b. slowed movements, balance and posture problems, rigid muscles, speech changes, and/or psychological symptoms such as dementia
  - c. impaired social skills, repetitive motor behaviors, strict adherence to certain rituals, and preoccupation with specific subjects
  - d. balance and posture problems, repetitive motor behaviors, difficulty with planning and executing tasks, poor judgment, and/or personality changes
- 15.** What treatment options are available for an individual diagnosed with major depression?
- a. blood pressure medication, deep-brain stimulation, taking monoamine oxidase inhibitors, psychotherapy, and physical therapy
  - b. psychotherapy, electroconvulsive therapy, deep-brain stimulation, taking monoamine oxidase inhibitors, and/or taking selective melatonin reuptake inhibitors
  - c. psychotherapy, electroconvulsive therapy, deep-brain stimulation, taking monoamine oxidase inhibitors, and/or taking selective serotonin reuptake inhibitors
  - d. blood pressure medication, classes of antipsychotics, psychotherapy, electroconvulsive therapy, deep-brain stimulation, and/or taking selective serotonin reuptake inhibitors

## TEST PREP FOR AP® COURSES

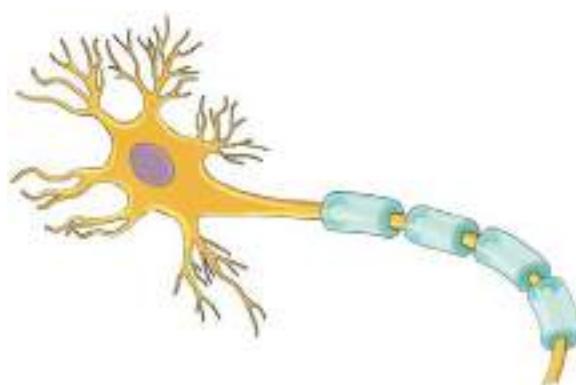

**16.** If a neuron has damaged synapses, what would be impaired?

- a. Integration of signals from several synapses
- b. Speed of signal transduction
- c. Receiving signals from other neurons
- d. Ability to recharge electrical signals

**17.** Signal transmission from one neuron to another requires a series of processes pertaining to different components of each neuron. What happens at the axon terminals to facilitate signal transmission to another neuron?

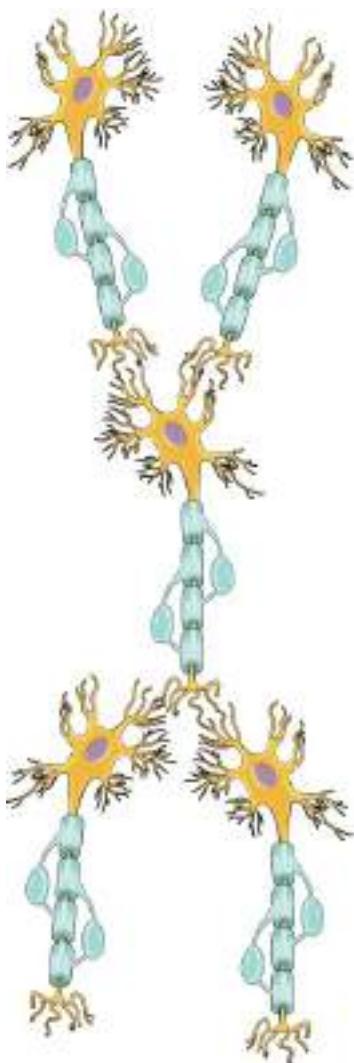

- a. Chemicals released at the axon terminals transmit signals through synapses into other neurons via the second neuron's dendrites.
- b. Chemicals released at the axon terminals transmit signals through synapses into other neurons via the second neuron's axons.
- c. Chemicals released at the dendrites transmit signals through synapses into other neurons via the second neuron's axon terminal.
- d. Chemicals released at the axon terminals transmit signals directly into other neurons via the second neuron's axons.

**18.** This figure shows a malformed neuron. Why would this neuron be nonfunctional?

- a. This neuron would not be able to receive signals.
- b. This neuron would not be able to recharge the signal.
- c. This neuron would not be able to integrate information from numerous synapses.
- d. This neuron would not be able to send signals.

**19.**

This figure shows the transmission of a signal among a network of neurons. How is a signal transferred from one neuron to another?

- A signal is released from an axon, passes through the axon terminal, and synapses with dendrites. Dendrites receive the signal, which passes through the soma. Multiple signals from a single synapse are integrated at the axon hillock, which then passes the signal into the axon, where the signal is transferred to another cell.
- A signal is released from axon terminal, passes through the axon, and synapse with dendrites. Dendrites receive the signal, which passes through the soma. Multiple signals from multiple synapses are integrated at the axon hillock, which then passes the signal into the axon, where the signal is transferred to another cell.
- A signal is released from an axon and passes through the axon terminal, which synapses with dendrites. Dendrites receive the signal as it passes through the soma. Multiple signals from multiple synapses are integrated at the axon hillock, which then passes the signal into the axon, where the signal is transferred to another cell.
- A signal is released from the axon terminal, passes through the axon, and synapse with dendrites. Dendrites receive the signal as it passes through the soma. Multiple signals from a single synapse are integrated at the axon hillock, which then passes the signal into the axon, where the signal is transferred to another cell.

**20.** Transmission of signals between two neurons requires proper communication between neurons. Dendrites are a component of many neurons that facilitate signal reception. Which of the following is true of dendrites?

- All neurons have several dendrites for signal reception.
- Dendritic spines decrease possible synaptic connections.
- Dendrites carry the signal to the soma.
- Chemical release at dendrites allows signal communication to other cells.

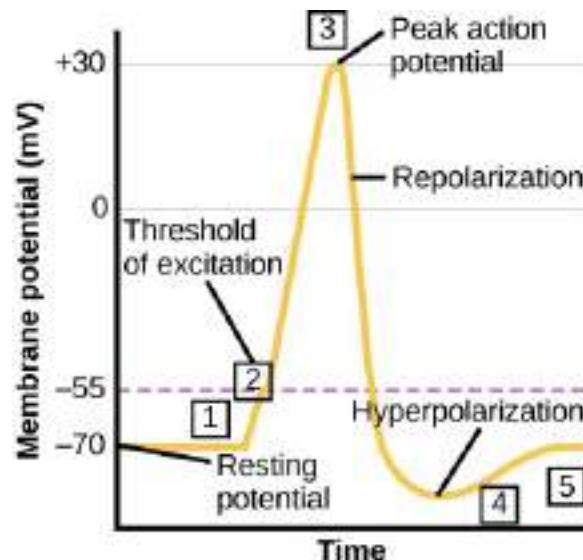

**21.**

| Ion Concentration Inside and Outside Neurons |                                  |                                  |                      |
|----------------------------------------------|----------------------------------|----------------------------------|----------------------|
| Ion                                          | Extracellular concentration (mM) | Intracellular concentration (mM) | Ratio outside/inside |
| 1                                            | 145                              | 12                               | 12                   |
| 2                                            | 4                                | 155                              | 0.026                |
| 3                                            | 120                              | 4                                | 30                   |
| Organic anions ( $\text{A}^-$ )              | —                                | 100                              |                      |

Resting membrane potential has a negative charge. Which ions correspond to each row of data in the chart?

- Ion 1:  $\text{Cl}^-$ , Ion 2:  $\text{Na}^+$ , Ion 3:  $\text{K}^+$
  - Ion 1:  $\text{Na}^+$ , Ion 2:  $\text{K}^+$ , Ion 3:  $\text{Cl}^-$
  - Ion 1:  $\text{K}^+$ , Ion 2:  $\text{Na}^+$ , Ion 3:  $\text{Cl}^-$
  - Ion 1:  $\text{Cl}^-$ , Ion 2:  $\text{K}^+$ , Ion 3:  $\text{Na}^+$
22. Voltage-gated ion channels are essential for producing an action potential and returning a neuron to its resting state. Why would it be impossible to trigger an action potential without voltage-gated ion channels?
- The cell would not undergo depolarization, which is necessary to fire an action potential and then return the cell to the resting state.
  - The cell would not undergo repolarization, which is necessary to fire an action potential and then return the cell to the resting state.
  - The cell would not undergo depolarization, repolarization, and hyperpolarization, which are necessary to fire an action potential and then return the cell to the resting state.
  - The cell would not undergo depolarization and hyperpolarization, which are necessary to fire an action potential and then return the cell to the resting state.

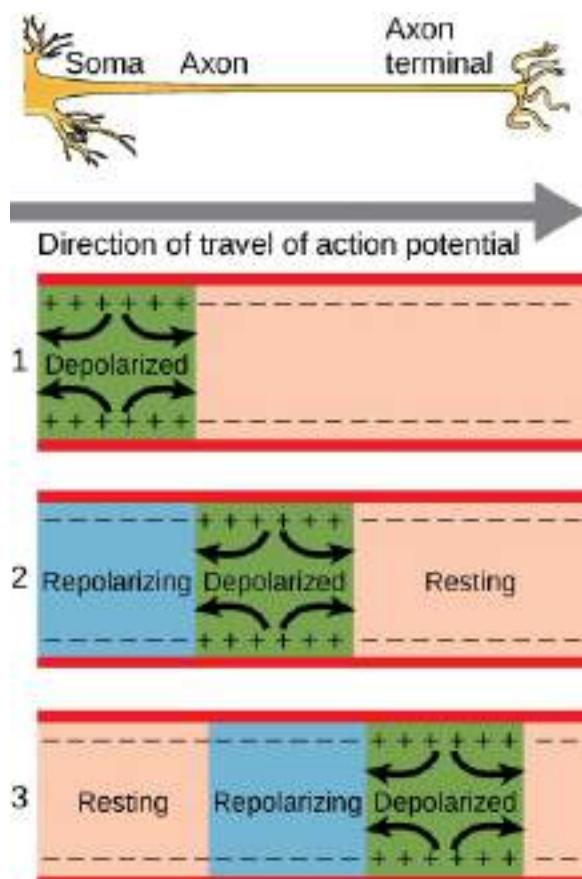

23.

When an action potential is fired, what happens immediately after the peak action potential occurs?

- $\text{Na}^+$  channels open.
  - $\text{K}^+$  channels open.
  - $\text{K}^+$  channels close.
  - $\text{Na}^+/\text{K}^+$  transporter restores resting potential.
24. Potassium channel blockers, such as amiodarone and procainamide, which are used to treat abnormal electrical activity in the heart, impede the movement of  $\text{K}^+$  through voltage-gated  $\text{K}^+$  channels. Which part of the action potential would potassium channels affect, and why?
- Depolarization after peak action potential would be affected because that is the point when  $\text{K}^+$  begins to leave the cell.
  - Repolarization after peak action potential would be affected because that is the point when  $\text{K}^+$  begins to leave the cell.
  - Repolarization after peak action potential would be affected because that is the point when  $\text{K}^+$  begins to enter the cell.
  - Polarization after peak action potential would be affected because that is the point when  $\text{K}^+$  begins to enter the cell.

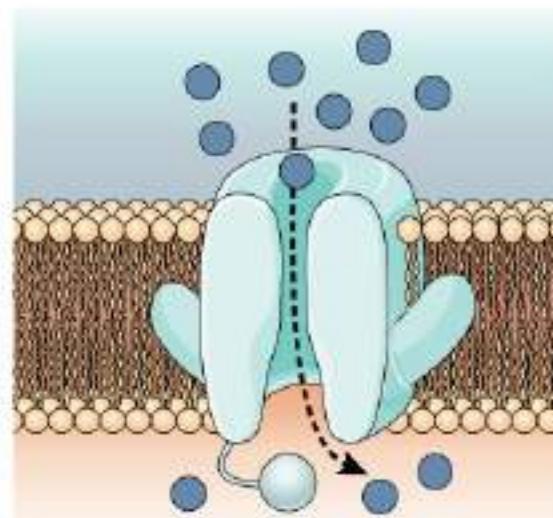

25.

This figure shows the transfer of an action potential through a neuron. What is occurring in panel 3?

- Depolarization occurs closest to the cell body.
- The first part of the neuron cannot fire another action potential.
- The first part of the neuron can fire another action potential.
- Sodium channels have closed.

26.

**Open** In response to a nerve impulse, the gate opens and Na<sup>+</sup> enters the cell.

This figure depicts an essential component of signal formation and transmission in neurons. What is happening in this figure?

- A nerve impulse opens the Na<sup>+</sup> channel, which makes Na<sup>+</sup> enter the cell and depolarizes the membrane.
- A nerve impulse opens the Ca<sup>2+</sup> channel, which makes Ca<sup>2+</sup> enter the cell and depolarizes the membrane.
- A nerve impulse opens the Na<sup>+</sup> channel, which makes Na<sup>+</sup> enter the cell and repolarizes the membrane.
- A nerve impulse opens the K<sup>+</sup> channel, which makes K<sup>+</sup> enter the cell and polarizes the membrane.

27. Chemical and electrical synapse are two mechanisms by which signals can be transferred between neurons. Which of the following occurs during chemical synapse?

- Repolariization at the presynaptic membrane
- Calcium influx causes synaptic vesicles to fuse to the membrane
- Neurotransmitters diffuse out of gap junctions
- Neurotransmitters bind to synaptic vesicles

28. Chemical synapse is a multiple-step process in which neurotransmitters undergo transfer and binding to different parts of the cell. What happens when a neurotransmitter binds to ligand-gated ion channels?

- a. The ligand-gated ion channels open.
- b. The presynaptic neuron reuptakes the neurotransmitter.
- c. The neurotransmitter diffuses away from the synapse.
- d. The neurotransmitter is enzymatically degraded.

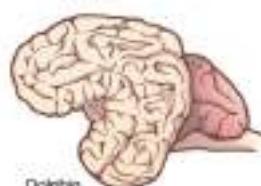

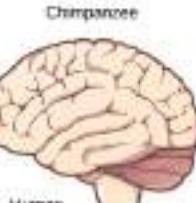

**29.** Different components of the brain control different parts of the body. One important part of the brain is the occipital lobe. What might happen if an individual's occipital lobe was damaged?

- a. The individual would not feel hot or cold.
- b. The individual would be unable to form new memories.
- c. The individual would be unable to recognize certain objects.
- d. The individual would have no sense of smell.

**30.** Both cerebral hemispheres are essential for proper body function. However, the left cerebral hemisphere controls the right side of the body, whereas the right cerebral hemisphere controls the left side of the body. Why is this the case?

- a. The descending neural connections are not switched in the brainstem, which means that the neural connections of the left hemisphere are transmitted to the right side of the body and vice versa.
- b. The ascending neural connections are not switched in the brainstem, which means that the neural connections of the left hemisphere are transmitted to the right side of the body and vice versa.
- c. The descending neural connections are switched in the brainstem, which means that the neural connections of the left hemisphere are transmitted to the right side of the body and vice versa.
- d. The ascending neural connections are switched in the brainstem, which means that the neural connections of the left hemisphere are transmitted to the right side of the body and vice versa.

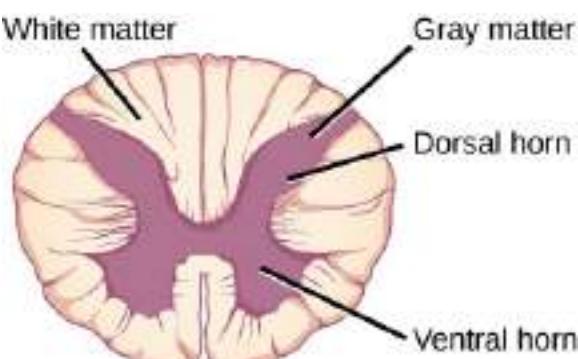

**31.**

If an increased number of folds in the cortical sheets of the brain is associated with increased social complexity, which of the following animals has the greatest social complexity?

- a. Rat
- b. Dolphin
- c. Chimpanzee
- d. Cat

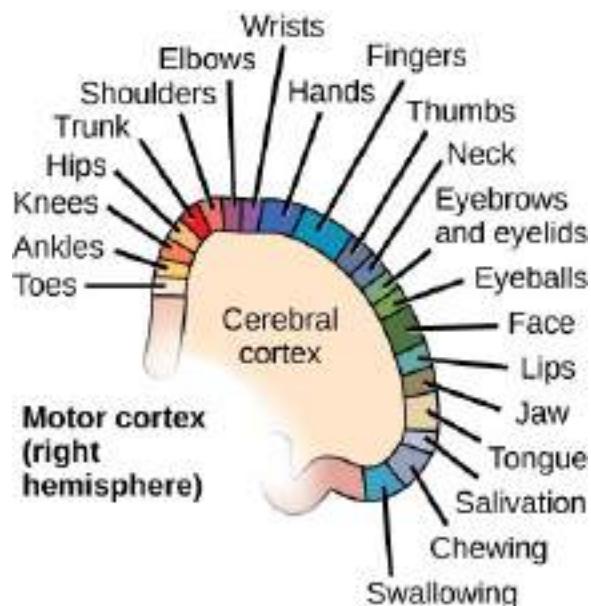

**32.**

This image shows a cross section of the spinal column. How does gray matter facilitate communication along the spinal column?

- All myelin sheaths are located in the gray matter, which transmit signals along the brain and spinal cord through the gray matter.
- All synapses are located in the gray matter, which transmit signals along the brain and spinal cord through the gray matter.
- All synapses are located in the gray matter, which transmit signals along the spinal cord through the gray matter.
- All dendrites are located in the gray matter, which transmit signals along the spinal cord through the gray matter.

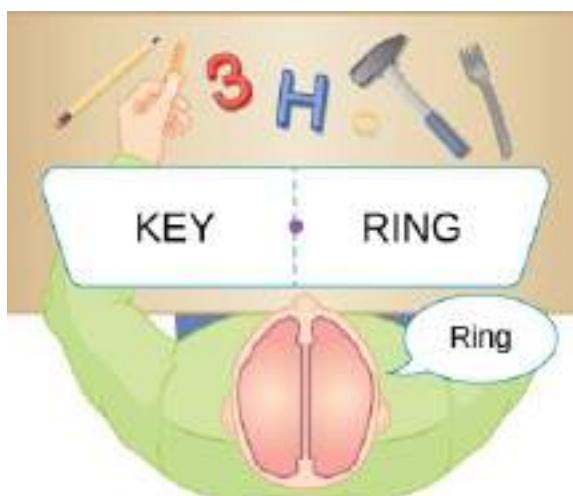

33.

This figure depicts the parts of the body that are controlled by different parts of the motor cortex. What can be inferred about the organization of the motor cortex relative to the organization of muscles in the body?

- The motor cortex is found throughout the body.
- Motor cortex neurons are generally located near neurons that control nearby body parts.
- Motor cortex neurons control speaking and processing what an individual reads.
- The motor cortex controls involuntary muscle movements.

34.

This figure represents a split-brain individual processing information. What has happened to the brain of this individual? Why does the processing of information occur as depicted?

- The parietal lobe has been cut, which severs the ability of the left hemisphere from communicating but increases the ability of the right hemisphere.
- The corpus callosum has been cut, which severs the ability of the left hemisphere from communicating but increases the ability of the right hemisphere.
- The frontal lobe has been cut, which severs the ability of the left and right hemispheres to communicate.
- The corpus callosum has been cut, which severs the ability of the left and right hemispheres to communicate.

35. The thalamus is part of the brain that is involved in various functions in the human body. What might result from the damage of an individual's thalamus?

- Insomnia
- Lack of interest in everything
- Lack of fear
- Inability to learn new motor tasks

## SCIENCE PRACTICE CHALLENGE QUESTIONS

36. A neurotransmitter provides a chemical signal between neurons to inhibit or excite an action potential.

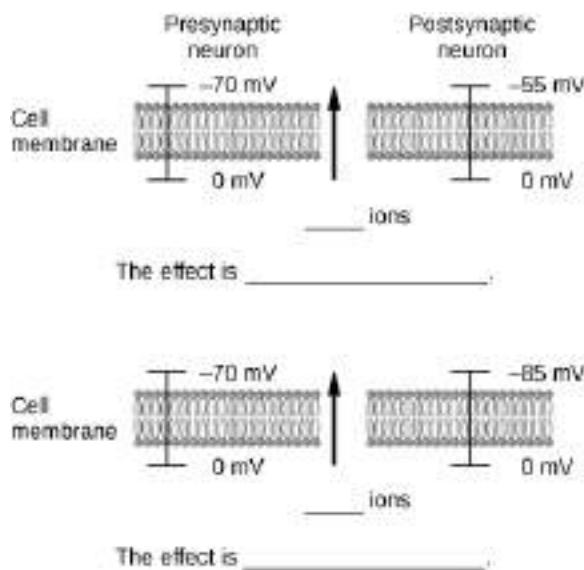

A. **Describe** a model of this signaling and in this

description include the roles played by synapse, receptors, post and pre-synaptic neurons, exocytosis, endocytosis, ligand-gated ion channel and the electric potential of the

membrane.

B. Explain the stimulatory or inhibitory effect of key ionic elements,  $\text{Na}^+$  and  $\text{Cl}^-$ , on the electric potential of the post-synaptic membrane.

C. Modify the diagram to create a representation of the effect explained above. Select from the following list to fill in the blanks:

**Figure 26.34**

- $\text{Na}^+$
- $\text{Cl}^-$
- stimulatory
- inhibitory

D. In the 1960s Burnstock and co-workers provided evidence that ATP is a neurotransmitter. This was received skeptically and largely rejected until 1984 when a modified form of ATP that was known to block the intracellular function of ATP was shown to effect extracellular signal transmission. Based on the central role played by ATP in biological systems **justify** the resistance within the scientific community to accept a role for ATP as a neurotransmitter. Based on the fact that ATP has been conserved throughout evolution of life on Earth **justify** such a role for ATP. Based on these two perspectives **analyze** the role of cooperative interactions in the positive selection of ATP as a neurotransmitter.

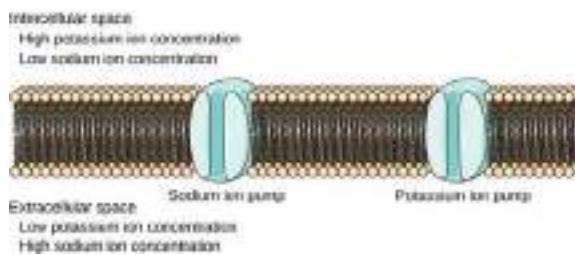

37. Neurons and muscle cells maintain a high concentration gradient of potassium ions across the plasma membrane. The extracellular space has a high concentration of sodium ions. At the rest electric potential the cell membrane is polarized.

A. Construct a representation of the cell membrane with annotation of the diagram below that includes the following:

- with a labeled arrow indicate the direction in which

the motion of potassium ions is driven by the concentration gradient

- with a labeled arrow indicate the direction in which the motion of sodium ions is driven by the concentration gradient
- give a brief statement of the roles of potassium and sodium ion pumps in maintaining the rest electric potential
- with a labeled arrow indicate the relative sign of the electric potential difference (voltage) between intracellular and extracellular spaces at the rest electric potential

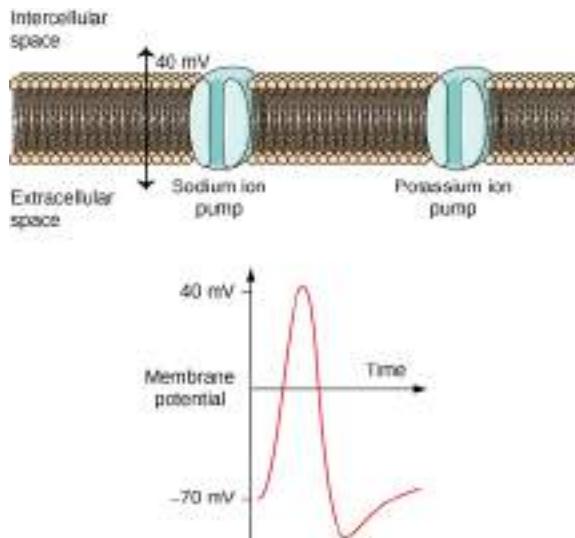

**Figure 26.35**

When an excitatory neurotransmitter receptor is activated the electric potential difference of membrane of a neuron is lowered inducing a change in the configuration of sodium pump proteins.

B. Justify the effect on the flux of sodium ions across the membrane as a positive feedback in a situation in which the electric potential difference falls below a threshold voltage and an action potential is created.

The action potential is transmitted along the neuron as a voltage wave. One cycle of the wave is shown below the diagram at the instant at which the maximum of the electric potential of the membrane has been reached.

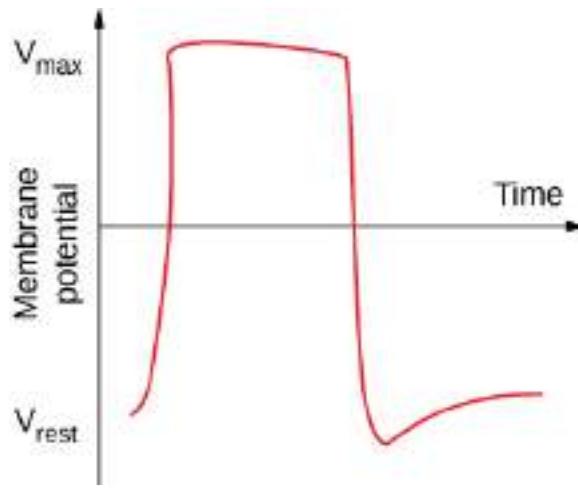

**Figure 26.36**

C. **Construct** a representation of the key elements of the signal propagation with annotation of the diagram that includes the following:

- a labeled arrow that indicates the direction in which the motion of potassium ions is driven by the concentration gradient
- a labeled arrow that indicates the direction in which the motion of potassium ions is driven by the electric potential difference across the membrane
- give a brief statement of the roles of potassium and sodium ion pumps in terminating the action potential

Most neurons must transmit a signal quickly. The sarcolemmas (muscle cell membranes) of the cardiac muscles receive signals that integrate information from both the sympathetic (quick response with shorter time scale) and parasympathetic (steady response with longer time scale) divisions of the autonomic nervous system. The action potential that induces periodic contractions of the cardiac muscle (see figure below) is broadened at the maximum by the release of  $\text{Ca}^{+2}$  from the smooth endoplasmic reticulum, referred to as calcium-induced calcium release (CICR).

**Figure 26.37**

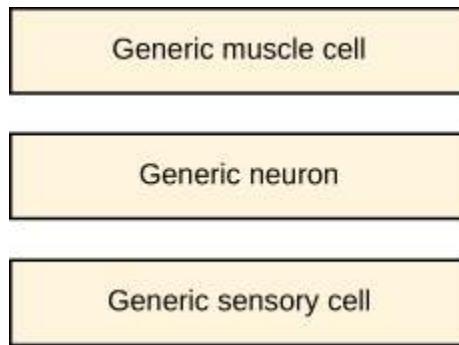

D. In terms of the function of the heart in the supply of oxygen and nutrients during “fight or flight” or restful conditions, **justify the claim** that this broadening demonstrates that the coordination of events must be regulated.

E. To stop a beating heart during open-heart surgery a solution of KCl is injected into the cardiac muscle.

**Explain** the effect of a large dose of extracellular  $\text{K}^+$  on the transmission of the action potential in the sarcolemma.

38. The brain integrates new information through the formation of memories and by learning. Alternative explanations of the ability of the brain to remodel in response to experience, called plasticity, are given. This item explores those explanations.

Consider the interaction of these three cell types that integrate information to produce a response to external cues:

**Figure 26.38**

A. Use the figure to **construct a representation** of the direction of information flow.

The central body of a neuron is elaborated by tree-like structures called dendrites. These allow the neuron to integrate information from multiple sensory receptors.

B. **Describe** what refinement of the basic stimulus-response system in the diagram is needed to achieve even the simplest response: “move away.” Awareness of orientation and motion within a body is called proprioception. **Describe** how multiple neurons are required to acquire proprioception.

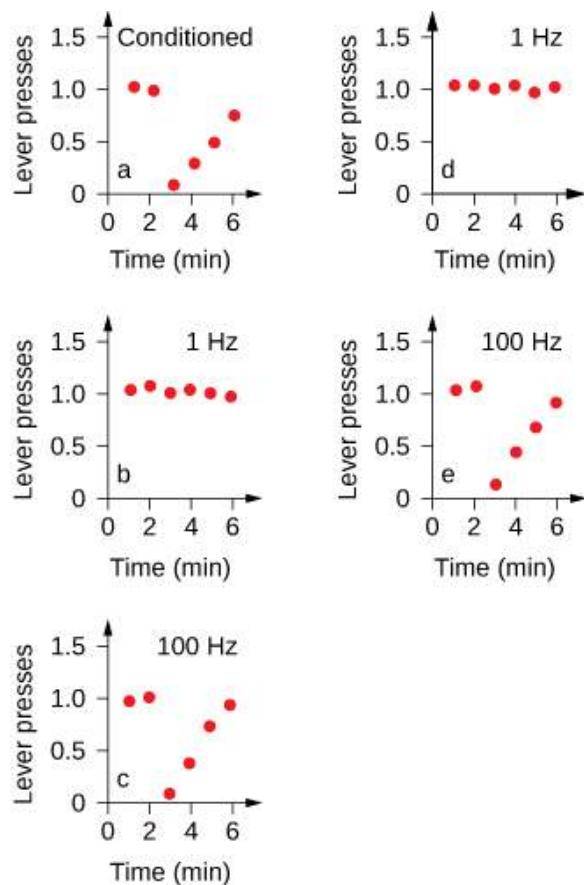

The generation of neurons occurs during development. However, adults continue to form memories and learn. Rearrangement of connections between neurons is a possible explanation and in several studies steroid hormones have been shown to produce dendritic plasticity. The hippocampus is active during memory formation and learning and significant variations in the number of dendrites were observed in the hippocampus (Wooley et al., *Journal of Neuroscience*, 10, 1990) were correlated with variations in estrogen during the estrus cycle. More recently variation in these structures is implicated in a collection of behaviors known as chronic unpredictable mild stress (CUMS). In rats CUMS can be induced by environmental factors such as electric shock, immobilization, or isolation (Qiao et al., *Neural Plasticity*, 2016).

C. **Pose two scientific questions** that can be investigated to connect the dynamic homeostasis and survival advantage of the individual to dendritic plasticity.

An alternative explanation of the manner in which the brain integrates new information is through synaptic plasticity. This has been demonstrated by Nabavi and co-workers (*Nature*, 511, 2014). An associated memory was created in a rat by pairing two stimuli: an audio tone and a foot shock. The animal had previously been trained to avoid pressing a lever that delivers a reward by associating the lever press with a shock. After conditioning the animal responded to the tone as if it was a shock and avoided

reward. The ratio of stimulatory to inhibitory receptors at the synaptic membrane was shown to increase with the experience.

A miniaturized device, optically activated and controlled by flashing light, was inserted in the nuclei of neurons transmitting the tone to the rat's brain. When the experimenters used light with 1 flash per second (1 Hz) the device caused the expression by the cell of one type of protein and when a light with 100 flashes per second (100 Hz) was used the device caused expression of another type of protein. Each of the graphs describe the response of the rat to environmental cues. One day elapsed between each data collection represented by one graph.

**Figure 26.39**

D. Analyze these data in terms of the evidence provided for synaptic plasticity.

A third explanation for the formation of memory and learning is found in the lab of David Glanzman (*Elife*, 2014). The sea slug (*Aplysia*) can be trained to withdraw its siphon tube. Sensory and motor neurons can be grown in tissue culture. The addition of serotonin to the tissue culture increases the number of synaptic connections and the training can be induced *in vitro*. Cells that had acquired the stimulus-response behavior were treated with an agent that destroys the synaptic receptors. Yet the trained response was retained and there were indications that the

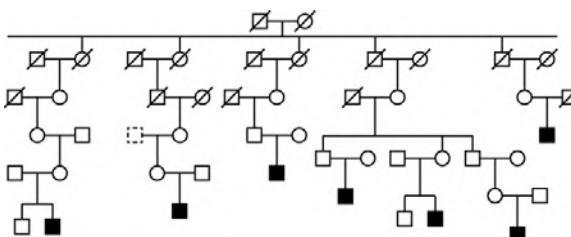

information was retrieved from the neuron nucleus.

E. Suppose that this work concerning the location of memory is confirmed. Create a representation of information flow in which a fourth box labeled "neuron nucleus" is added to the diagram in part A between the stimulus and the neuron. Annotate the representation to indicate the flow of information.

**Explain Pose questions** regarding the ethical or social consequences of this technology.

- how this form of plasticity is more dynamic than theories in which memory resides in synaptic or dendritic structures, and
- how it might lead to treatments for disorders, such as post-traumatic stress syndrome, in which recollection creates a disability.

39. Autism is a collection of communication and socialization behaviors. Evidence of inheritance of genes predisposing the individual during early development is indicated by pedigrees such as the following (after Allen-Brady, Molecular Psychiatry, 14, 2009). Males (squares) and females (circles) are affected when the symbol is filled, are struck through when deceased and the genome cannot be determined, and are dashed when living and the genome was not determined.

**Figure 26.40**

A. Other evidence indicates that autism is not x-linked. Give an alternative explanation that can account for these data.

B. Stem cells taken from fathers who do not present characteristic of autism and from their sons were induced to form tissue cultures of neurons. Compared to the father those taken from the son showed accelerated growth with a higher number of synapses. Describe possible consequences for the integration of information if this *in vitro* growth also occurs *in vivo*.

The variety of phenotypes and large number of genes that have been implicated in this disorder have led researchers to refer to the characteristics as autisms described by a spectrum of disorders, ASD. One of the gene implicated is *bola2*. While humans and other primates have genomes that are reported to have only a 2% deviation the particular form of *bola2* that occurs in 99% of human genomes that have been mapped does not occur in other primates. And *bola2* is not present in the Neanderthal genome. Even more interesting is that single nucleotide variations in human *bola2* are significantly less frequent than genes

associated with other brain disorders such as schizophrenia.

**C. Evaluate** the selection pressure and direction (positive or negative) indicated by this observation.

D. Several hundred genes have been implicated in ASD and many others probably will eventually be discovered. Expression in a gene networks can depend on factors that are both genetic and environmental. Given the complexity of ASD **what questions should be researched** by the physician of children or their parents when genetic screening is considered?

**40. Describe** how neurons transmit information.

**41.** You are probably acquainted with the effects of local anesthetics. While the injection of lidocaine at the dentist is unpleasant no injection would be more so. Lidocaine is a sodium channel blocker.

A. **Explain** the absence of pain in terms of the effect of lidocaine on signal reception and transduction.

The pain of the dentist's drill is caused by trauma at the cellular level. Chemical messengers such as cytokines, serotonin, and prostaglandins are released by broken cells. The receptors for these messages of trauma are called nociceptors whose activation is transmitted to the central nervous system by specialized cells called the A and C fibres.

B. The nervous system is a network of cells and tissues that is activated by these chemical messengers. **Identify** another system that should be activated by these messengers and **support your claim** by applying the idea that dynamic homeostasis is maintained by timing and coordination of regulated events.

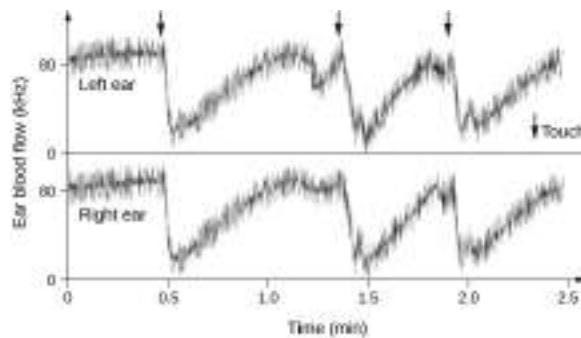

C. Chronic pain often persists after damaged tissue has healed. This pain is often accompanied by sterile inflammation with components of the innate immune system such as macrophages. **Refine the model** of coordinated response identified in part B to describe how chemical messengers associated with the immune response can cause chronic pain.

Unlike local anesthetics general anesthetics block signal

transduction of the entire central nervous system and the brain. However, while the patient is unconscious the peripheral nervous system continues to support signaling to other systems such as heart and lungs. An explanation might be that the signal in the central and peripheral nervous systems are segregated and that the latter functions without cognitive integration (thought) as the name "autonomic" implies. The respiratory center that provides autonomic control of breathing is part of the medulla oblongata.

D. **Create a visual representation** of system composed only of the cortex, the medulla oblongata, the heart and the lungs. Using arrows describe the flow of information. Consider "holding your breath" in creating your representation. Consider why you always stop holding your breath eventually. Consider "holding your heart." Experimental data on the voluntary control of heart rate by people who practice yoga have been reported (Raghavendra et al., *International Journal of Yoga*, 6, 2013; Telles et al., *Integrative Physiological and Behavioral Science*, 39, 2004).

E. **Analyze** the data provided in the following sketch of blood flow, a process controlled by the autonomic nervous system, in the two ears of a rabbit (after Blessing, *Trends in Neuroscience*, 20, 1997) in terms of cognitive integration of the response to the stimulus provided by touching the rabbit.

**Figure 26.41**

# 27 | SENSORY SYSTEMS

**Figure 27.1** This shark uses its senses of sight, vibration (lateral-line system), and smell to hunt, but it also relies on its ability to sense the electric fields of prey, a sense not present in most land animals. (credit: modification of work by Hermanus Backpackers Hostel, South Africa)

## Chapter Outline

- 27.1: Sensory Processes**
- 27.2: Somatosensation**
- 27.3: Taste and Smell**
- 27.4: Hearing and Vestibular Sensation**
- 27.5: Vision**

## Introduction

All bilaterally symmetric animals have a sensory system, the development of which has been driven by natural selection. Thus, sensory systems differ among species according to the demands of their environments. Animals' senses are constantly at work, making them aware of stimuli, such as light, or sound, or the presence of a chemical substance in the external environment. They also monitor information about the organism's internal environment. The shark pictured above has the ability to perceive natural electrical stimuli produced by other animals in its environment, a sense called electroreception. This enhanced ability to sense prey gives the shark an evolutionary advantage over other fish. While it is helpful to this underwater predator, electroreception is a sense not found in most land animals. You can read more about electroreception in sharks at the [Sharks info website \(<http://openstax.org/l/32sharks>\)](http://openstax.org/l/32sharks).

## Connection for AP<sup>®</sup> Courses

The content in this chapter is not within the scope of AP<sup>®</sup> other than to recognize the link between the sensory organs and the nervous system. The ability to detect and respond to information is critical to an organism's survival and fitness. If time permits, you might explore the evolution of one type of sensory receptor (photoreceptors, chemoreceptor, thermoreceptor, or proprioceptor) in several different animal species, with special consideration of the features that allow it to convert a stimulus to a nerve impulse. (This task is an application of information in Big Idea 1 of the AP<sup>®</sup> Curriculum Framework—that the evolution of a structure such as a sensory receptor supports the concept that evolution continues to occur.)

## 27.1 | Sensory Processes

In this section, you will explore the following questions:

- What are the general and special senses in humans?
- What are three important steps in sensory perception?
- What is the concept of just-noticeable difference in sensory perception?

Senses provide information about the body and its environment. Humans have five special senses: olfaction (smell), gustation (taste), equilibrium (balance and body position), vision, and hearing. Additionally, we possess general senses, also called somatosensation, which respond to stimuli like temperature, pain, pressure, and vibration. **Vestibular sensation**, which is an organism's sense of spatial orientation and balance, **proprioception** (position of bones, joints, and muscles), and the sense of limb position that is used to track **kinesthesia** (limb movement) are part of somatosensation. Although the sensory systems associated with these senses are very different, all share a common function: to convert a stimulus (such as light, or sound, or the position of the body) into an electrical signal in the nervous system. This process is called **sensory transduction**.

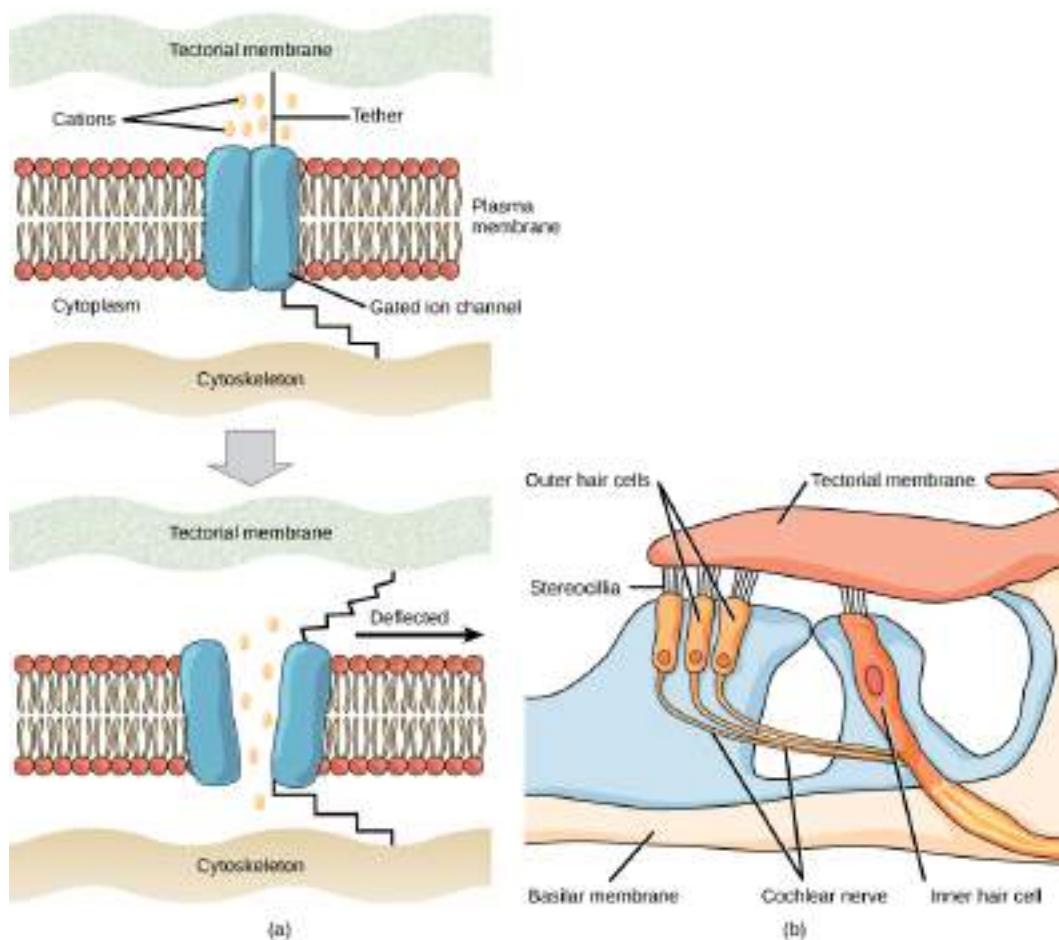

There are two broad types of cellular systems that perform sensory transduction. In one, a neuron works with a **sensory receptor**, a cell, or cell process that is specialized to engage with and detect a specific stimulus. Stimulation of the sensory receptor activates the associated afferent neuron, which carries information about the stimulus to the central nervous system. In the second type of sensory transduction, a sensory nerve ending responds to a stimulus in the internal or external environment: this neuron constitutes the sensory receptor. Free nerve endings can be stimulated by several different stimuli, thus showing little receptor specificity. For example, pain receptors in your gums and teeth may be stimulated by temperature changes, chemical stimulation, or pressure.

### Reception

The first step in sensation is **reception**, which is the activation of sensory receptors by stimuli such as mechanical stimuli (being bent or squished, for example), chemicals, or temperature. The receptor can then respond to the stimuli. The region in space in which a given sensory receptor can respond to a stimulus, be it far away or in contact with the body, is that receptor's **receptive field**. Think for a moment about the differences in receptive fields for the different senses. For the sense of touch, a stimulus must come into contact with body. For the sense of hearing, a stimulus can be a moderate distance away (some baleen whale sounds can propagate for many kilometers). For vision, a stimulus can be very far away; for example, the visual system perceives light from stars at enormous distances.

### Transduction

The most fundamental function of a sensory system is the translation of a sensory signal to an electrical signal in the nervous system. This takes place at the sensory receptor, and the change in electrical potential that is produced is called the **receptor potential**. How is sensory input, such as pressure on the skin, changed to a receptor potential? In this example, a type of receptor called a **mechanoreceptor** (as shown in [Figure 27.2](#)) possesses specialized membranes that respond to pressure. Disturbance of these dendrites by compressing them or bending them opens gated ion channels in the plasma membrane of the sensory neuron, changing its electrical potential. Recall that in the nervous system, a positive change of a neuron's electrical potential (also called the membrane potential), depolarizes the neuron. Receptor potentials are graded potentials: the magnitude of these graded (receptor) potentials varies with the strength of the stimulus. If the magnitude of depolarization is sufficient (that is, if membrane potential reaches a threshold), the neuron will fire an action potential. In most cases, the correct stimulus impinging on a sensory receptor will drive membrane potential in a positive direction, although for some receptors, such as those in the visual system, this is not always the case.

**Figure 27.2** (a) Mechanosensitive ion channels are gated ion channels that respond to mechanical deformation of the plasma membrane. A mechanosensitive channel is connected to the plasma membrane and the cytoskeleton by hair-like tethers. When pressure causes the extracellular matrix to move, the channel opens, allowing ions to enter or exit the cell. (b) Stereocilia in the human ear are connected to mechanosensitive ion channels. When a sound causes the stereocilia to move, mechanosensitive ion channels transduce the signal to the cochlear nerve.

Sensory receptors for different senses are very different from each other, and they are specialized according to the type of stimulus they sense: they have receptor specificity. For example, touch receptors, light receptors, and sound receptors are each activated by different stimuli. Touch receptors are not sensitive to light or sound; they are sensitive only to touch or pressure. However, stimuli may be combined at higher levels in the brain, as happens with olfaction, contributing to our sense of taste.

#### Encoding and Transmission of Sensory Information

Four aspects of sensory information are encoded by sensory systems: the type of stimulus, the location of the stimulus in the receptive field, the duration of the stimulus, and the relative intensity of the stimulus. Thus, action potentials transmitted over a sensory receptor's afferent axons encode one type of stimulus, and this segregation of the senses is preserved in other sensory circuits. For example, auditory receptors transmit signals over their own dedicated system, and electrical activity in the axons of the auditory receptors will be interpreted by the brain as an auditory stimulus—a sound.

The intensity of a stimulus is often encoded in the rate of action potentials produced by the sensory receptor. Thus, an intense stimulus will produce a more rapid train of action potentials, and reducing the stimulus will likewise slow the rate of production of action potentials. A second way in which intensity is encoded is by the number of receptors activated. An intense stimulus might initiate action potentials in a large number of adjacent receptors, while a less intense stimulus might stimulate fewer receptors. Integration of sensory information begins as soon as the information is received in the CNS, and the brain will further process incoming signals.

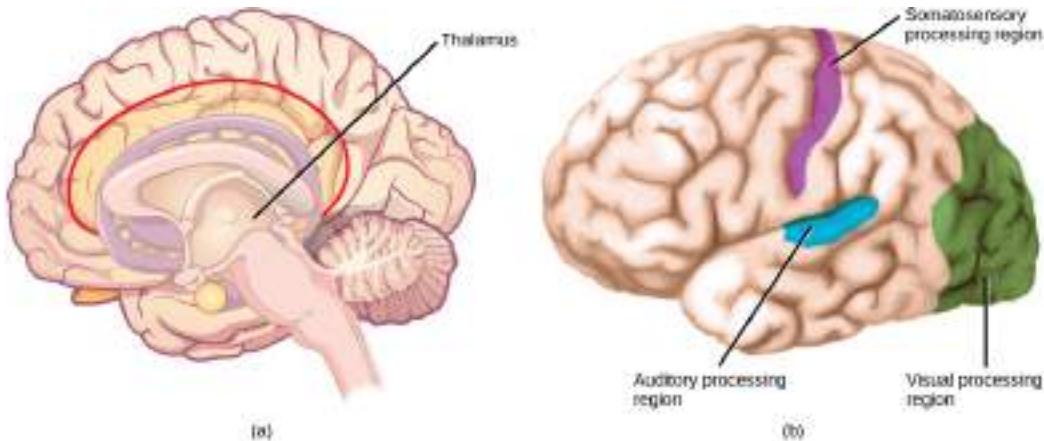

## Perception

**Perception** is an individual's interpretation of a sensation. Although perception relies on the activation of sensory receptors,

perception happens not at the level of the sensory receptor, but at higher levels in the nervous system, in the brain. The brain distinguishes sensory stimuli through a sensory pathway: action potentials from sensory receptors travel along neurons that are dedicated to a particular stimulus. These neurons are dedicated to that particular stimulus and synapse with particular neurons in the brain or spinal cord.

All sensory signals, except those from the olfactory system, are transmitted through the central nervous system and are routed to the thalamus and to the appropriate region of the cortex. Recall that the thalamus is a structure in the forebrain that serves as a clearinghouse and relay station for sensory (as well as motor) signals. When the sensory signal exits the thalamus, it is conducted to the specific area of the cortex (**Figure 27.3**) dedicated to processing that particular sense.

How are neural signals interpreted? Interpretation of sensory signals between individuals of the same species is largely similar, owing to the inherited similarity of their nervous systems; however, there are some individual differences. A good example of this is individual tolerances to a painful stimulus, such as dental pain, which certainly differ.

**Figure 27.3** In humans, with the exception of olfaction, all sensory signals are routed from the (a) thalamus to (b) final processing regions in the cortex of the brain. (credit b: modification of work by Polina Tishina)

## scientific method CONNECTION

### Just-Noticeable Difference

It is easy to differentiate between a one-pound bag of rice and a two-pound bag of rice. There is a one-pound difference, and one bag is twice as heavy as the other. However, would it be as easy to differentiate between a 20- and a 21-pound bag?

**Question:** What is the smallest detectable weight difference between a one-pound bag of rice and a larger bag? What is the smallest detectable difference between a 20-pound bag and a larger bag? In both cases, at what weights are the differences detected? This smallest detectable difference in stimuli is known as the just-noticeable difference (JND).

**Background:** Research background literature on JND and on Weber's Law, a description of a proposed mathematical relationship between the overall magnitude of the stimulus and the JND. You will be testing JND of different weights of rice in bags. Choose a convenient increment that is to be stepped through while testing. For example, you could choose 10 percent increments between one and two pounds (1.1, 1.2, 1.3, 1.4, and so on) or 20 percent increments (1.2, 1.4, 1.6, and 1.8).

**Hypothesis:** Develop a hypothesis about JND in terms of percentage of the whole weight being tested (such as "the JND between the two small bags and between the two large bags is proportionally the same," or ". . . is not proportionally the same.") So, for the first hypothesis, if the JND between the one-pound bag and a larger bag is 0.2 pounds (that is, 20 percent; 1.0 pound feels the same as 1.1 pounds, but 1.0 pound feels less than 1.2 pounds), then the JND between the 20-pound bag and a larger bag will also be 20 percent. (So, 20 pounds feels the same as 22 pounds or 23 pounds, but 20 pounds feels less than 24 pounds.)

**Test the hypothesis:** Enlist 24 participants, and split them into two groups of 12. To set up the demonstration, assuming a 10 percent increment was selected, have the first group be the one-pound group. As a counter-balancing measure against a systematic error, however, six of the first group will compare one pound to two pounds, and step down in weight (1.0 to 2.0, 1.0 to 1.9, and so on.), while the other six will step up (1.0 to 1.1, 1.0 to 1.2, and so on). Apply the same principle to the 20-pound group (20 to 40, 20 to 38, and so on, and 20 to 22, 20 to 24, and so on). Given the large difference between 20 and 40 pounds, you may wish to use 30 pounds as your larger weight. In any case, use two weights that are easily detectable as different.

**Record the observations:** Record the data in a table similar to the table below. For the one-pound and 20-pound groups (base weights) record a plus sign (+) for each participant that detects a difference between the base weight and the step weight. Record a minus sign (-) for each participant that finds no difference. If one-tenth steps were not used, then replace the steps in the "Step Weight" columns with the step you are using.

**Results of JND Testing (+ = difference; - = no difference)**

| Step Weight | One pound | 20 pounds | Step Weight |
|-------------|-----------|-----------|-------------|
| 1.1         |           |           | 22          |
| 1.2         |           |           | 24          |
| 1.3         |           |           | 26          |
| 1.4         |           |           | 28          |
| 1.5         |           |           | 30          |
| 1.6         |           |           | 32          |
| 1.7         |           |           | 34          |
| 1.8         |           |           | 36          |

### Results of JND Testing (+ = difference; – = no difference)

| Step Weight | One pound | 20 pounds | Step Weight |
|-------------|-----------|-----------|-------------|
| 1.9         |           |           | 38          |
| 2.0         |           |           | 40          |

Table 27.1

**Analyze the data/report the results:** What step weight did all participants find to be equal with one-pound base weight? What about the 20-pound group?

**Draw a conclusion:** Did the data support the hypothesis? Are the final weights proportionally the same? If not, why not? Do the findings adhere to Weber's Law? Weber's Law states that the concept that a just-noticeable difference in a stimulus is proportional to the magnitude of the original stimulus.

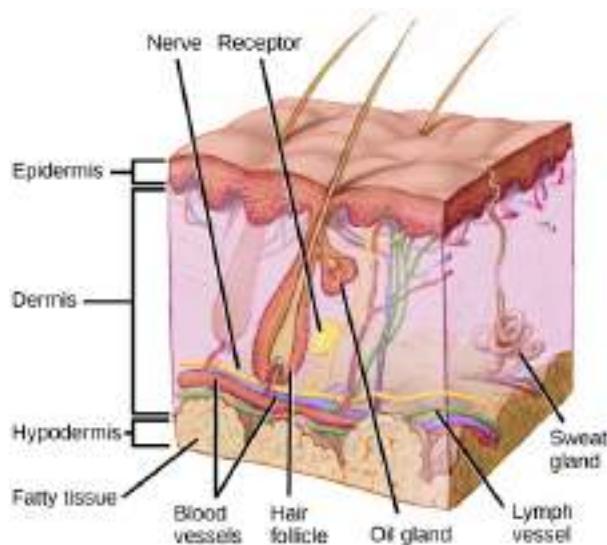

## 27.2 | Somatosensation

In this section, you will explore the following questions:

- What are four important mechanoreceptors in human skin?
- What is the topographical distribution of somatosensory receptors between glabrous and hairy skin?
- Why is the perception of pain subjective?

Somatosensation is a mixed sensory category and includes all sensation received from the skin and mucous membranes, as well from the limbs and joints. Somatosensation is also known as tactile sense, or more familiarly, as the sense of touch. Somatosensation occurs all over the exterior of the body and at some interior locations as well. A variety of receptor types—embedded in the skin, mucous membranes, muscles, joints, internal organs, and cardiovascular system—play a role.

Recall that the epidermis is the outermost layer of skin in mammals. It is relatively thin, is composed of keratin-filled cells, and has no blood supply. The epidermis serves as a barrier to water and to invasion by pathogens. Below this, the much thicker dermis contains blood vessels, sweat glands, hair follicles, lymph vessels, and lipid-secreting sebaceous glands ([Figure 27.4](#)). Below the epidermis and dermis is the subcutaneous tissue, or hypodermis, the fatty layer that contains blood vessels, connective tissue, and the axons of sensory neurons. The hypodermis, which holds about 50 percent of the body's fat, attaches the dermis to the bone and muscle, and supplies nerves and blood vessels to the dermis.

**Figure 27.4** Mammalian skin has three layers: an epidermis, a dermis, and a hypodermis. (credit: modification of work by Don Bliss, National Cancer Institute)

## Somatosensory Receptors

Sensory receptors are classified into five categories: mechanoreceptors, thermoreceptors, proprioceptors, pain receptors, and chemoreceptors. These categories are based on the nature of stimuli each receptor class transduces. What is commonly referred to as “touch” involves more than one kind of stimulus and more than one kind of receptor. Mechanoreceptors in the skin are described as encapsulated (that is, surrounded by a capsule) or unencapsulated (a group that includes free nerve endings). A **free nerve ending**, as its name implies, is an unencapsulated dendrite of a sensory neuron. Free nerve endings are the most common nerve endings in skin, and they extend into the middle of the epidermis. Free nerve endings are sensitive to painful stimuli, to hot and cold, and to light touch. They are slow to adjust to a stimulus and so are less sensitive to abrupt changes in stimulation.

There are three classes of mechanoreceptors: tactile, proprioceptors, and baroreceptors. Mechanoreceptors sense stimuli due to physical deformation of their plasma membranes. They contain mechanically gated ion channels whose gates open or close in response to pressure, touch, stretching, and sound.” There are four primary tactile mechanoreceptors in human skin: Merkel’s disks, Meissner’s corpuscles, Ruffini endings, and Pacinian corpuscle; two are located toward the surface of the skin and two are located deeper. A fifth type of mechanoreceptor, Krause end bulbs, are found only in specialized regions. **Merkel’s disks** (shown in **Figure 27.5**) are found in the upper layers of skin near the base of the epidermis, both in skin that has hair and on **glabrous** skin, that is, the hairless skin found on the palms and fingers, the soles of the feet, and the lips of humans and other primates. Merkel’s disks are densely distributed in the fingertips and lips. They are slow-adapting, encapsulated nerve endings, and they respond to light touch. Light touch, also known as discriminative touch, is a light pressure that allows the location of a stimulus to be pinpointed. The receptive fields of Merkel’s disks are small with well-defined borders. That makes them finely sensitive to edges and they come into use in tasks such as typing on a keyboard.

**visual CONNECTION**

The diagram illustrates the cross-section of human skin showing the epidermis and dermis layers. Four types of mechanoreceptors are depicted:

- Merkel's disk:** Unencapsulated, consisting of flattened, overlapping nerve endings.
- Meissner's corpuscle:** Encapsulated, a small, rounded structure.
- Ruffini ending:** Encapsulated, a bulbous structure.
- Pacinian corpuscle:** Encapsulated, a large, multi-layered structure.

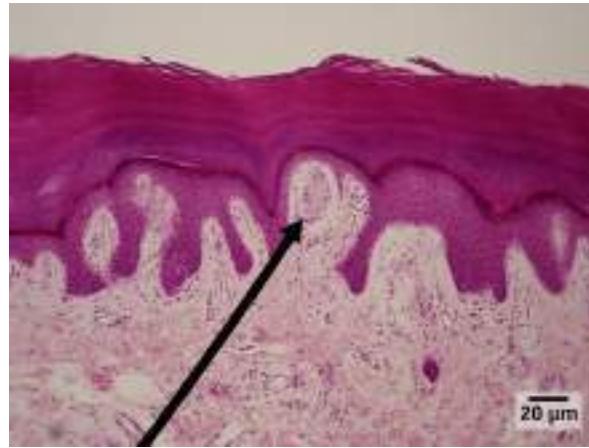

A **Nerve** is shown connecting the receptors to the body. Labels indicate the **Epidermis** and **Dermis**.

**Figure 27.5** Four of the primary mechanoreceptors in human skin are shown. Merkel's disks, which are unencapsulated, respond to light touch. Meissner's corpuscles, Ruffini endings, Pacinian corpuscles, and Krause end bulbs are all encapsulated. Meissner's corpuscles respond to touch and low-frequency vibration. Ruffini endings detect stretch, deformation within joints, and warmth. Pacinian corpuscles detect transient pressure and high-frequency vibration. Krause end bulbs detect cold.

Which of the following statements about mechanoreceptors is true?

- Meissner's corpuscles extend far into the epidermis.
- Ruffini endings are the only encapsulated mechanoreceptors.
- Light touch is detected by Pacinian corpuscles.
- Merkel's disks are abundant on the fingertips and lips.

**Meissner's corpuscles**, (shown in **Figure 27.6**) also known as tactile corpuscles, are found in the upper dermis, but they project into the epidermis. They, too, are found primarily in the glabrous skin on the fingertips and eyelids. They respond to fine touch and pressure, but they also respond to low-frequency vibration or flutter. They are rapidly adapting, fluid-filled, encapsulated neurons with small, well-defined borders and are responsive to fine details. Like Merkel's disks, Meissner's corpuscles are not as plentiful in the palms as they are in the fingertips.

**Figure 27.6** Meissner corpuscles in the fingertips, such as the one viewed here using bright field light microscopy, allow for touch discrimination of fine detail. (credit: modification of work by "Wbennsmith"/Wikimedia Commons; scale-bar data from Matt Russell)

Deeper in the epidermis, near the base, are **Ruffini endings**, which are also known as bulbous corpuscles. They are found in both glabrous and hairy skin. These are slow-adapting, encapsulated mechanoreceptors that detect skin stretch and deformations within joints, so they provide valuable feedback for gripping objects and controlling finger position and movement. Thus, they also contribute to proprioception and kinesthesia. Ruffini endings also detect warmth. Note that these

warmth detectors are situated deeper in the skin than are the cold detectors. It is not surprising, then, that humans detect cold stimuli before they detect warm stimuli.

**Pacinian corpuscles** (seen in [Figure 27.7](#)) are located deep in the dermis of both glabrous and hairy skin and are structurally similar to Meissner's corpuscles; they are found in the bone periosteum, joint capsules, pancreas and other viscera, breast, and genitals. They are rapidly adapting mechanoreceptors that sense deep transient (but not prolonged) pressure and high-frequency vibration. Pacinian receptors detect pressure and vibration by being compressed, stimulating their internal dendrites. There are fewer Pacinian corpuscles and Ruffini endings in skin than there are Merkel's disks and Meissner's corpuscles.

**Figure 27.7** Pacinian corpuscles, such as these visualized using bright field light microscopy, detect pressure (touch) and high-frequency vibration. (credit: modification of work by Ed Uthman; scale-bar data from Matt Russell)

In proprioception, proprioceptive and kinesthetic signals travel through myelinated afferent neurons running from the spinal cord to the medulla. Neurons are not physically connected, but communicate via neurotransmitters secreted into synapses or "gaps" between communicating neurons. Once in the medulla, the neurons continue carrying the signals to the thalamus.

**Muscle spindles** are stretch receptors that detect the amount of stretch, or lengthening of muscles. Related to these are **Golgi tendon organs**, which are tension receptors that detect the force of muscle contraction. Proprioceptive and kinesthetic signals come from limbs. Unconscious proprioceptive signals run from the spinal cord to the cerebellum, the brain region that coordinates muscle contraction, rather than to the thalamus, like most other sensory information.

Baroreceptors detect pressure changes in an organ. They are found in the walls of the carotid artery and the aorta where they monitor blood pressure, and in the lungs where they detect the degree of lung expansion. Stretch receptors are found at various sites in the digestive and urinary systems.

In addition to these two types of deeper receptors, there are also rapidly adapting hair receptors, which are found on nerve endings that wrap around the base of hair follicles. There are a few types of hair receptors that detect slow and rapid hair movement, and they differ in their sensitivity to movement. Some hair receptors also detect skin deflection, and certain rapidly adapting hair receptors allow detection of stimuli that have not yet touched the skin.

### **Integration of Signals from Mechanoreceptors**

The configuration of the different types of receptors working in concert in human skin results in a very refined sense of touch. The nociceptive receptors—those that detect pain—are located near the surface. Small, finely calibrated mechanoreceptors—Merkel's disks and Meissner's corpuscles—are located in the upper layers and can precisely localize even gentle touch. The large mechanoreceptors—Pacinian corpuscles and Ruffini endings—are located in the lower layers and respond to deeper touch. (Consider that the deep pressure that reaches those deeper receptors would not need to be finely localized.) Both the upper and lower layers of the skin hold rapidly and slowly adapting receptors. Both primary somatosensory cortex and secondary cortical areas are responsible for processing the complex picture of stimuli transmitted from the interplay of mechanoreceptors.

### **Density of Mechanoreceptors**

The distribution of touch receptors in human skin is not consistent over the body. In humans, touch receptors are less dense in skin covered with any type of hair, such as the arms, legs, torso, and face. Touch receptors are denser in glabrous skin

(the type found on human fingertips and lips, for example), which is typically more sensitive and is thicker than hairy skin (4 to 5 mm versus 2 to 3 mm).

How is receptor density estimated in a human subject? The relative density of pressure receptors in different locations on the body can be demonstrated experimentally using a two-point discrimination test. In this demonstration, two sharp points, such as two thumbtacks, are brought into contact with the subject's skin (though not hard enough to cause pain or break the skin). The subject reports if he or she feels one point or two points. If the two points are felt as one point, it can be inferred that the two points are both in the receptive field of a single sensory receptor. If two points are felt as two separate points, each is in the receptive field of two separate sensory receptors. The points could then be moved closer and re-tested until the subject reports feeling only one point, and the size of the receptive field of a single receptor could be estimated from that distance.

## Thermoreception

In addition to Krause end bulbs that detect cold and Ruffini endings that detect warmth, there are different types of cold receptors on some free nerve endings: thermoreceptors, located in the dermis, skeletal muscles, liver, and hypothalamus, that are activated by different temperatures. Their pathways into the brain run from the spinal cord through the thalamus to the primary somatosensory cortex. Warmth and cold information from the face travels through one of the cranial nerves to the brain. You know from experience that a tolerably cold or hot stimulus can quickly progress to a much more intense stimulus that is no longer tolerable. Any stimulus that is too intense can be perceived as pain because temperature sensations are conducted along the same pathways that carry pain sensations

## Pain

Pain is the name given to **nociception**, which is the neural processing of injurious stimuli in response to tissue damage. Pain is caused by true sources of injury, such as contact with a heat source that causes a thermal burn or contact with a corrosive chemical. But pain also can be caused by harmless stimuli that mimic the action of damaging stimuli, such as contact with capsaicins, the compounds that cause peppers to taste hot and which are used in self-defense pepper sprays and certain topical medications. Peppers taste "hot" because the protein receptors that bind capsaicin open the same calcium channels that are activated by warm receptors.

Nociception starts at the sensory receptors, but pain, in-as-much as it is the perception of nociception, does not start until it is communicated to the brain. There are several nociceptive pathways to and through the brain. Most axons carrying nociceptive information into the brain from the spinal cord project to the thalamus (as do other sensory neurons) and the neural signal undergoes final processing in the primary somatosensory cortex. Interestingly, one nociceptive pathway projects not to the thalamus but directly to the hypothalamus in the forebrain, which modulates the cardiovascular and neuroendocrine functions of the autonomic nervous system. Recall that threatening—or painful—stimuli stimulate the sympathetic branch of the visceral sensory system, readying a fight-or-flight response.

View this [video](http://openstaxcollege.org/l/nociceptive) (<http://openstaxcollege.org/l/nociceptive>) that animates the five phases of nociceptive pain.

Select the stimulus that can activate the nociceptive system.

- a. a pleasant melody on a harp
- b. a delicious apple
- c. the aroma of freshly baked cookies
- d. burning your hand on a stove

## 27.3 | Taste and Smell

In this section, you will explore the following questions:

- In what way do smell and taste stimuli differ from other sensory stimuli?
- What are the five primary tastes that can be distinguished by humans?
- In anatomical terms why is a dog's sense of smell more acute than a human's?

Taste, also called **gustation**, and smell, also called **olfaction**, are the most interconnected senses in that both involve molecules of the stimulus entering the body and bonding to receptors. Smell lets an animal sense the presence of food or other animals—whether potential mates, predators, or prey—or other chemicals in the environment that can impact their survival. Similarly, the sense of taste allows animals to discriminate between types of foods. While the value of a sense of smell is obvious, what is the value of a sense of taste? Different tasting foods have different attributes, both helpful and harmful. For example, sweet-tasting substances tend to be highly caloric, which could be necessary for survival in lean times. Bitterness is associated with toxicity, and sourness is associated with spoiled food. Salty foods are valuable in maintaining homeostasis by helping the body retain water and by providing ions necessary for cells to function.

### Tastes and Odors

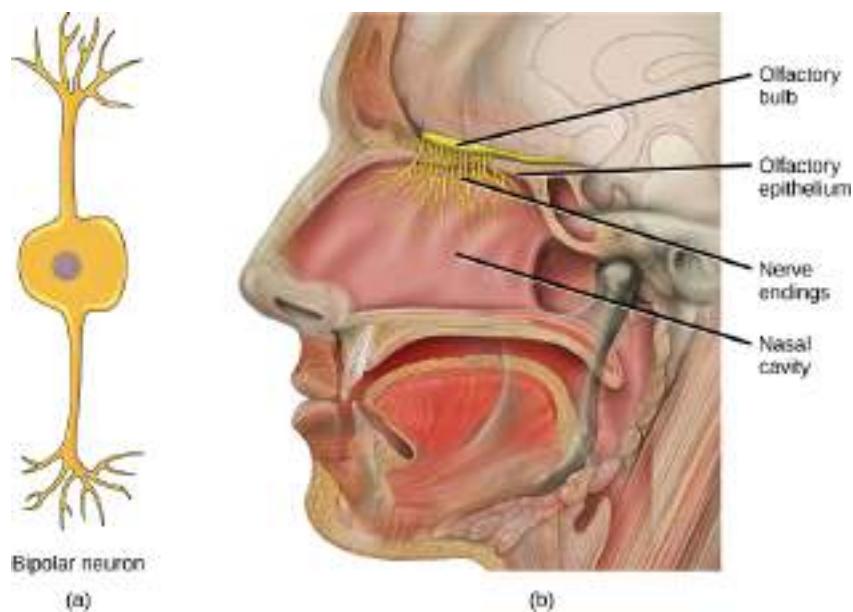

Both taste and odor stimuli are molecules taken in from the environment. The primary tastes detected by humans are sweet, sour, bitter, salty and umami. The first four tastes need little explanation. The identification of **umami** as a fundamental taste occurred fairly recently—it was identified in 1908 by Japanese scientist Kikunae Ikeda while he worked with seaweed broth, but it was not widely accepted as a taste that could be physiologically distinguished until many years later. The taste of umami, also known as savoriness, is attributable to the taste of the amino acid L-glutamate. In fact, monosodium glutamate, or MSG, is often used in cooking to enhance the savory taste of certain foods. What is the adaptive value of being able to distinguish umami? Savory substances tend to be high in protein.

All odors that we perceive are molecules in the air we breathe. If a substance does not release molecules into the air from its surface, it has no smell. And if a human or other animal does not have a receptor that recognizes a specific molecule, then that molecule has no smell. Humans have about 350 olfactory receptor subtypes that work in various combinations to allow us to sense about 10,000 different odors. Compare that to mice, for example, which have about 1,300 olfactory receptor types, and therefore probably sense more odors. Both odors and tastes involve molecules that stimulate specific chemoreceptors. Although humans commonly distinguish taste as one sense and smell as another, they work together to create the perception of flavor. A person's perception of flavor is reduced if he or she has congested nasal passages.

### Reception and Transduction

**Odorants** (odor molecules) enter the nose and dissolve in the olfactory epithelium, the mucosa at the back of the nasal cavity (as illustrated in [Figure 27.8](#)). The **olfactory epithelium** is a collection of specialized olfactory receptors in the back of the nasal cavity that spans an area about  $5\text{ cm}^2$  in humans. Recall that sensory cells are neurons. An **olfactory receptor**, which is a dendrite of a specialized neuron, responds when it binds certain molecules inhaled from the environment by sending impulses directly to the olfactory bulb of the brain. Humans have about 12 million olfactory receptors, distributed among hundreds of different receptor types that respond to different odors. Twelve million seems like a large number of receptors, but compare that to other animals: rabbits have about 100 million, most dogs have about 1 billion, and bloodhounds—dogs selectively bred for their sense of smell—have about 4 billion. The overall size of the olfactory epithelium also differs between species, with that of bloodhounds, for example, being many times larger than that of humans.

Olfactory neurons are **bipolar neurons** (neurons with two processes from the cell body). Each neuron has a single dendrite buried in the olfactory epithelium, and extending from this dendrite are 5 to 20 receptor-laden, hair-like cilia that trap odorant molecules. The sensory receptors on the cilia are proteins, and it is the variations in their amino acid chains that make the receptors sensitive to different odorants. Each olfactory sensory neuron has only one type of receptor on its cilia, and the receptors are specialized to detect specific odorants, so the bipolar neurons themselves are specialized. When an odorant binds with a receptor that recognizes it, the sensory neuron associated with the receptor is stimulated. Olfactory stimulation is the only sensory information that directly reaches the cerebral cortex, whereas other sensations are relayed through the thalamus.

**Figure 27.8** In the human olfactory system, (a) bipolar olfactory neurons extend from (b) the olfactory epithelium, where olfactory receptors are located, to the olfactory bulb. (credit: modification of work by Patrick J. Lynch, medical illustrator; C. Carl Jaffe, MD, cardiologist)

# evolution CONNECTION

## Pheromones

A **pheromone** is a chemical released by an animal that affects the behavior or physiology of animals of the same species. Pheromonal signals can have profound effects on animals that inhale them, but pheromones apparently are not consciously perceived in the same way as other odors. There are several different types of pheromones, which are released in urine or as glandular secretions. Certain pheromones are attractants to potential mates, others are repellants to potential competitors of the same sex, and still others play roles in mother-infant attachment. Some pheromones can also influence the timing of puberty, modify reproductive cycles, and even prevent embryonic implantation. While the roles of pheromones in many nonhuman species are important, pheromones have become less important in human behavior over evolutionary time compared to their importance to organisms with more limited behavioral repertoires.

The vomeronasal organ (VNO, or Jacobson's organ) is a tubular, fluid-filled, olfactory organ present in many vertebrate animals that sits adjacent to the nasal cavity. It is very sensitive to pheromones and is connected to the nasal cavity by a duct. When molecules dissolve in the mucosa of the nasal cavity, they then enter the VNO where the pheromone molecules among them bind with specialized pheromone receptors. Upon exposure to pheromones from their own species or others, many animals, including cats, may display the *flehmen response* (shown in **Figure 27.9**), a curling of the upper lip that helps pheromone molecules enter the VNO.

Pheromonal signals are sent, not to the main olfactory bulb, but to a different neural structure that projects directly to the amygdala (recall that the amygdala is a brain center important in emotional reactions, such as fear). The pheromonal signal then continues to areas of the hypothalamus that are key to reproductive physiology and behavior. While some scientists assert that the VNO is apparently functionally vestigial in humans, even though there is a similar structure located near human nasal cavities, others are researching it as a possible functional system that may, for example, contribute to synchronization of menstrual cycles in women living in close proximity.

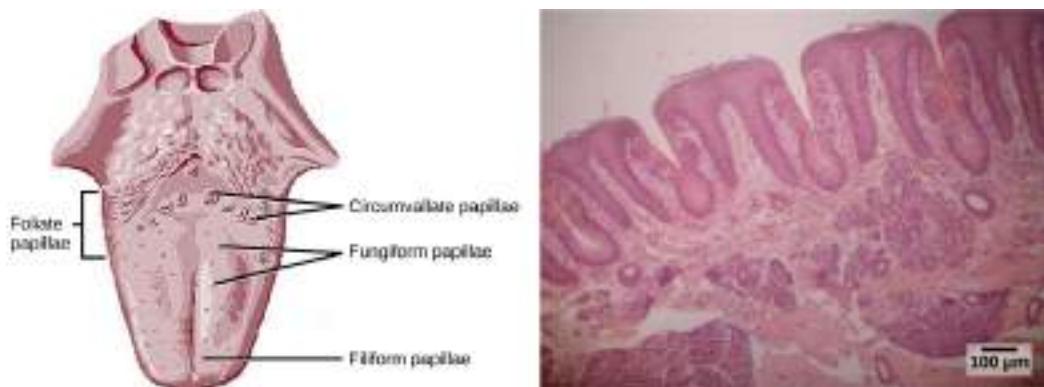

**Figure 27.9** The *flehmen response* in this tiger results in the curling of the upper lip and helps airborne pheromone molecules enter the vomeronasal organ. (credit: modification of work by "chadh"/Flickr)

Describe how a male snake can physiologically detect the presence of a female that is trying to attract a mate.

- The pheromones secreted by a female dissolve and enter the vomeronasal organ. The dissolved molecules bind to receptors, which send a signal to the hypothalamus, which in turn sends the signal to the amygdala.
- The pheromones secreted by a female dissolve and enter the vomeronasal organ. The dissolved molecules bind to receptors, which send a signal to the amygdala, which in turn sends the signal to the hypothalamus.
- The pheromones secreted by a female dissolve and enter the amygdala. The dissolved molecules bind to receptors, which send a signal to the vomeronasal organ, which in turn sends the signal to the hypothalamus.
- The pheromones secreted by a female dissolve and enter the amygdala. The dissolved molecules bind to receptors, which send a signal to the hypothalamus, which in turn sends the signal to the vomeronasal organ.

## Taste

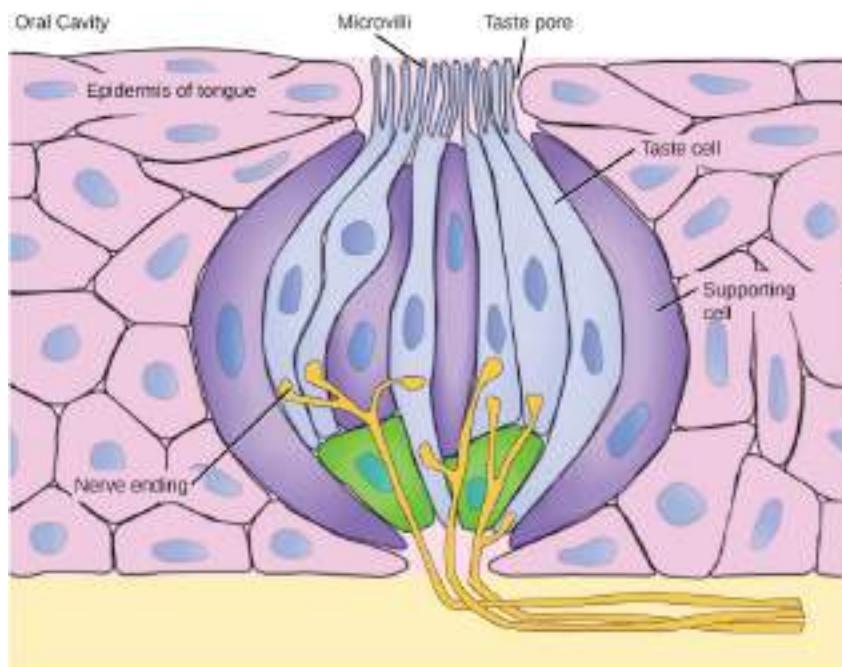

Detecting a taste (gustation) is fairly similar to detecting an odor (olfaction), given that both taste and smell rely on chemical receptors being stimulated by certain molecules. The primary organ of taste is the taste bud. A **taste bud** is a cluster of gustatory receptors (taste cells) that are located within the bumps on the tongue called **papillae** (singular: papilla) (illustrated in [Figure 27.10](#)). There are several structurally distinct papillae. Filiform papillae, which are located across the tongue, are tactile, providing friction that helps the tongue move substances, and contain no taste cells. In contrast, fungiform papillae, which are located mainly on the anterior two-thirds of the tongue, each contain one to eight taste buds and also have receptors for pressure and temperature. The large circumvallate papillae contain up to 100 taste buds and form a V near the posterior margin of the tongue.

**Figure 27.10** (a) Foliate, circumvallate, and fungiform papillae are located on different regions of the tongue. (b) Foliate papillae are prominent protrusions on this light micrograph. (credit a: modification of work by NCI; scale-bar data from Matt Russell)

In addition to those two types of chemically and mechanically sensitive papillae are foliate papillae—leaf-like papillae located in parallel folds along the edges and toward the back of the tongue, as seen in the [Figure 27.10](#) micrograph. Foliate papillae contain about 1,300 taste buds within their folds. Finally, there are circumvallate papillae, which are wall-like papillae in the shape of an inverted “V” at the back of the tongue. Each of these papillae is surrounded by a groove and contains about 250 taste buds.

Each taste bud's taste cells are replaced every 10 to 14 days. These are elongated cells with hair-like processes called microvilli at the tips that extend into the taste bud pore (illustrate in [Figure 27.11](#)). Food molecules (**tastants**) are dissolved in saliva, and they bind with and stimulate the receptors on the microvilli. The receptors for tastants are located across the outer portion and front of the tongue, outside of the middle area where the filiform papillae are most prominent.

**Figure 27.11** Pores in the tongue allow tastants to enter taste pores in the tongue. (credit: modification of work by Vincenzo Rizzo)

In humans, there are five primary tastes, and each taste has only one corresponding type of receptor. Thus, like olfaction, each receptor is specific to its stimulus (tastant). Transduction of the five tastes happens through different mechanisms that reflect the molecular composition of the tastant. A salty tastant (containing NaCl) provides the sodium ions ( $\text{Na}^+$ ) that enter the taste neurons and excite them directly. Sour tastants are acids and belong to the thermoreceptor protein family. Binding of an acid or other sour-tasting molecule triggers a change in the ion channel and these increase hydrogen ion ( $\text{H}^+$ ) concentrations in the taste neurons, thus depolarizing them. Sweet, bitter, and umami tastants require a G-protein coupled receptor. These tastants bind to their respective receptors, thereby exciting the specialized neurons associated with them.

Both tasting abilities and sense of smell change with age. In humans, the senses decline dramatically by age 50 and continue to decline. A child may find a food to be too spicy, whereas an elderly person may find the same food to be bland and unappetizing.

View this **animation** (<http://openstaxcollege.org/l/taste>) that shows how the sense of taste works.

Which of the following is true about human taste?

- a. Taste buds are covered in papillae.
- b. Saliva contains taste receptor cells.
- c. Papillae stimulate the hair-like endings of taste buds.
- d. The hair-like endings of taste buds generate nerve impulses to the brain.

## Smell and Taste in the Brain

Olfactory neurons project from the olfactory epithelium to the olfactory bulb as thin, unmyelinated axons. The **olfactory bulb** is composed of neural clusters called **glomeruli**, and each glomerulus receives signals from one type of olfactory receptor, so each glomerulus is specific to one odorant. From glomeruli, olfactory signals travel directly to the olfactory cortex and then to the frontal cortex and the thalamus. Recall that this is a different path from most other sensory information, which is sent directly to the thalamus before ending up in the cortex. Olfactory signals also travel directly to the amygdala, thereafter reaching the hypothalamus, thalamus, and frontal cortex. The last structure that olfactory signals directly travel to is a cortical center in the temporal lobe structure important in spatial, autobiographical, declarative, and episodic memories. Olfaction is finally processed by areas of the brain that deal with memory, emotions, reproduction, and thought.

Taste neurons project from taste cells in the tongue, esophagus, and palate to the medulla, in the brainstem. From the medulla, taste signals travel to the thalamus and then to the primary gustatory cortex. Information from different regions of the tongue is segregated in the medulla, thalamus, and cortex.

## 27.4 | Hearing and Vestibular Sensation

In this section, you will explore the following questions:

- What is the relationship of amplitude and frequency of a sound wave to the attributes of sound?
- What path does sound travel within the auditory system to the site of transduction of sound?
- What are the structures of the vestibular system that respond to gravity?

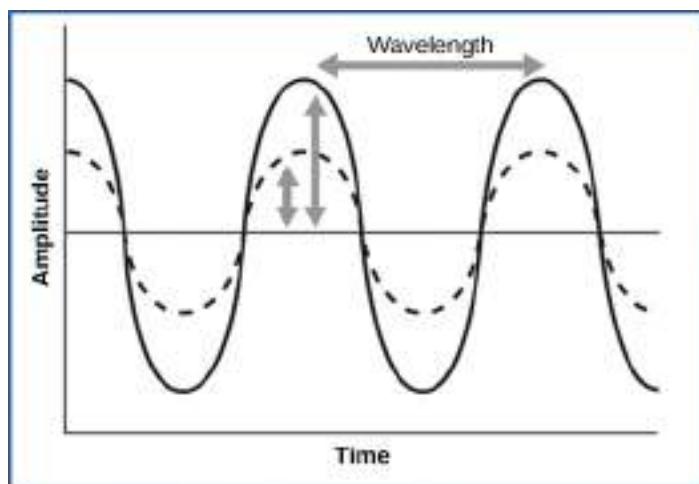

**Audition**, or hearing, is important to humans and to other animals for many different interactions. It enables an organism to detect and receive information about danger, such as an approaching predator, and to participate in communal exchanges like those concerning territories or mating. On the other hand, although it is physically linked to the auditory system, the vestibular system is not involved in hearing. Instead, an animal's vestibular system detects its own movement, both linear and angular acceleration and deceleration, and balance.

### Sound

Auditory stimuli are sound waves, which are mechanical, pressure waves that move through a medium, such as air or water. There are no sound waves in a vacuum since there are no air molecules to move in waves. The speed of sound waves differs, based on altitude, temperature, and medium, but at sea level and a temperature of 20° C (68° F), sound waves travel in the air at about 343 meters per second.

As is true for all waves, there are four main characteristics of a sound wave: frequency, wavelength, period, and amplitude. Frequency is the number of waves per unit of time, and in sound is heard as pitch. High-frequency ( $\geq 15,000\text{Hz}$ ) sounds are higher-pitched (short wavelength) than low-frequency (long wavelengths;  $\leq 100\text{Hz}$ ) sounds. Frequency is measured in cycles per second, and for sound, the most commonly used unit is hertz (Hz), or cycles per second. Most humans can perceive sounds with frequencies between 30 and 20,000 Hz. Women are typically better at hearing high frequencies, but everyone's ability to hear high frequencies decreases with age. Dogs detect up to about 40,000 Hz; cats, 60,000 Hz; bats, 100,000 Hz; and dolphins 150,000 Hz, and American shad (*Alosa sapidissima*), a fish, can hear 180,000 Hz. Those frequencies above the human range are called **ultrasound**.

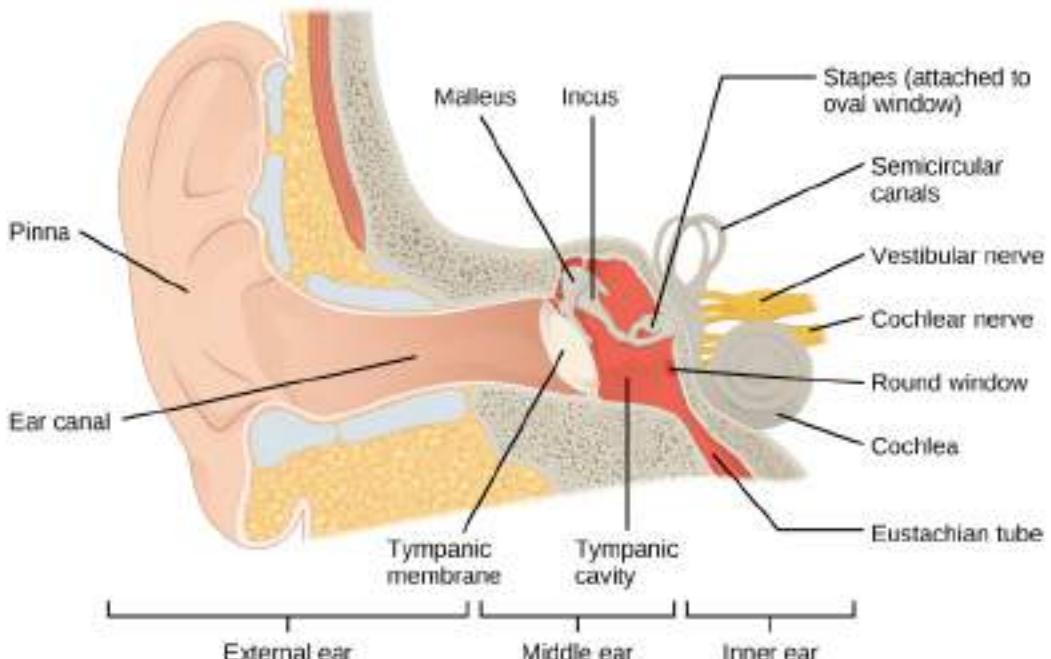

Amplitude, or the dimension of a wave from peak to trough, in sound is heard as volume and is illustrated in **Figure 27.12**. The sound waves of louder sounds have greater amplitude than those of softer sounds. For sound, volume is measured in decibels (dB). The softest sound that a human can hear is the zero point. Humans speak normally at 60 decibels.

**Figure 27.12** For sound waves, wavelength corresponds to pitch. Amplitude of the wave corresponds to volume. The sound wave shown with a dashed line is softer in volume than the sound wave shown with a solid line. (credit: NIH)

## Reception of Sound

In mammals, sound waves are collected by the external, cartilaginous part of the ear called the **pinna**, then travel through the auditory canal and cause vibration of the thin diaphragm called the **tympanum** or ear drum, the innermost part of the **outer ear** (illustrated in **Figure 27.13**). Interior to the tympanum is the **middle ear**. The middle ear holds three small bones called the **ossicles**, which transfer energy from the moving tympanum to the inner ear. The three ossicles are the **malleus** (also known as the hammer), the **incus** (the anvil), and **stapes** (the stirrup). The aptly named stapes looks very much like a stirrup. The three ossicles are unique to mammals, and each plays a role in hearing. The malleus attaches at three points to the interior surface of the tympanic membrane. The incus attaches the malleus to the stapes. In humans, the stapes is not long enough to reach the tympanum. If we did not have the malleus and the incus, then the vibrations of the tympanum would never reach the inner ear. These bones also function to collect force and amplify sounds. The ear ossicles are homologous to bones in a fish mouth: the bones that support gills in fish are thought to be adapted for use in the vertebrate ear over evolutionary time. Many animals (frogs, reptiles, and birds, for example) use the stapes of the middle ear to transmit vibrations to the middle ear.

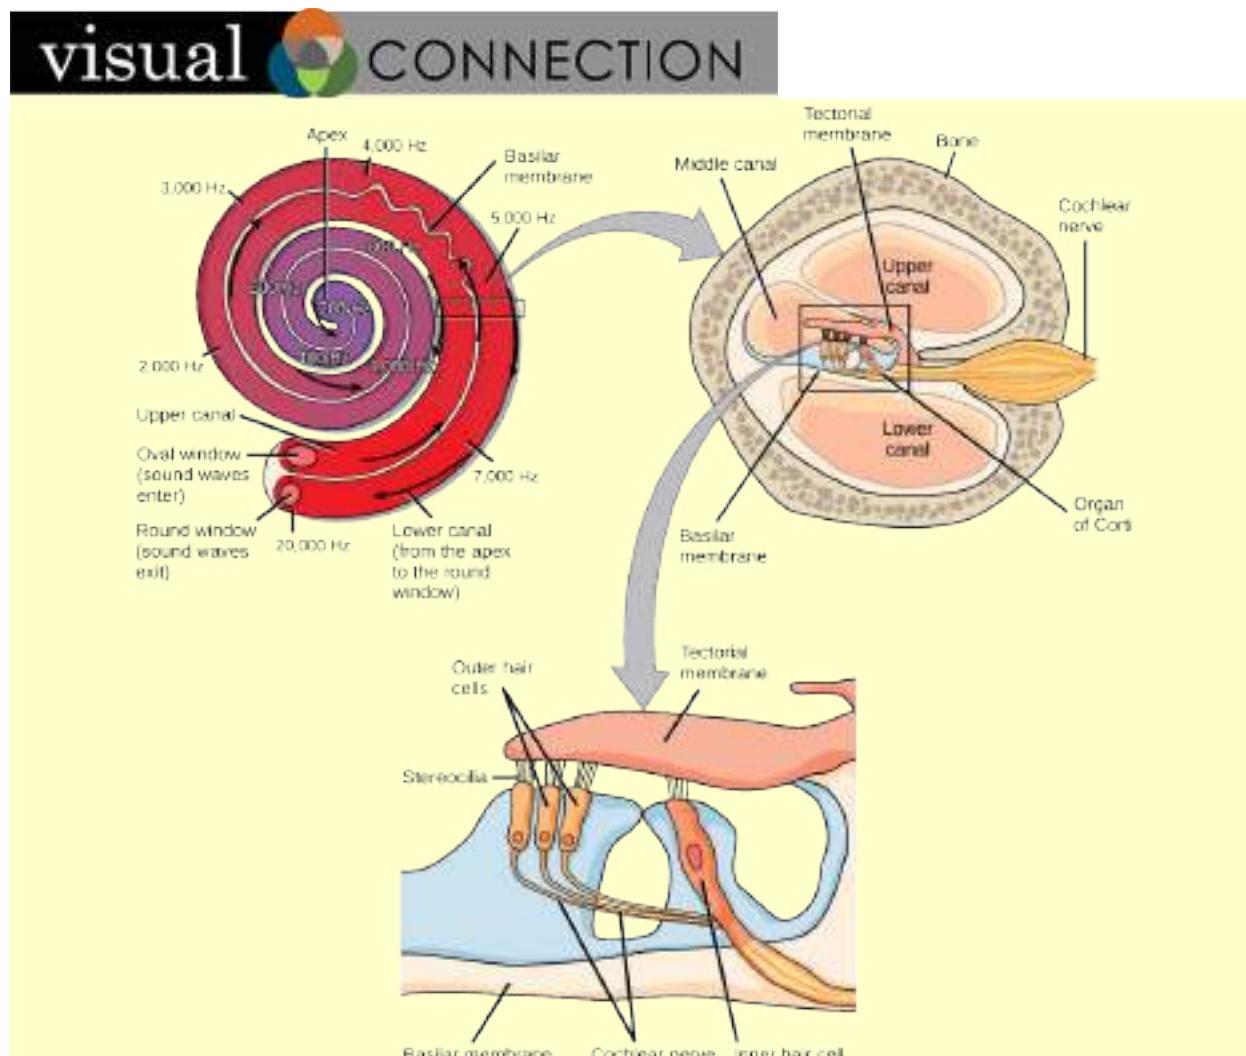

**Figure 27.13** Sound travels through the outer ear to the middle ear, which is bounded on its exterior by the tympanic membrane. The middle ear contains three bones called ossicles that transfer the sound wave to the oval window, the exterior boundary of the inner ear. The organ of Corti, which is the organ of sound transduction, lies inside the cochlea.

## Transduction of Sound

Vibrating objects, such as vocal cords, create sound waves or pressure waves in the air. When these pressure waves reach the ear, the ear transduces this mechanical stimulus (pressure wave) into a nerve impulse (electrical signal) that the brain perceives as sound. The pressure waves strike the tympanum, causing it to vibrate. The mechanical energy from the moving tympanum transmits the vibrations to the three bones of the middle ear. The stapes transmits the vibrations to a thin diaphragm called the **oval window**, which is the outermost structure of the **inner ear**. The structures of the inner ear are found in the **labyrinth**, a bony, hollow structure that is the most interior portion of the ear. Here, the energy from the sound wave is transferred from the stapes through the flexible oval window and to the fluid of the cochlea. The vibrations of the oval window create pressure waves in the fluid (perilymph) inside the cochlea. The **cochlea** is a whorled structure, like the shell of a snail, and it contains receptors for transduction of the mechanical wave into an electrical signal (as illustrated in [Figure 27.14](#)). Inside the cochlea, the **basilar membrane** is a mechanical analyzer that runs the length of the cochlea, curling toward the cochlea's center.

The mechanical properties of the basilar membrane change along its length, such that it is thicker, tauter, and narrower at the outside of the whorl (where the cochlea is largest), and thinner, floppier, and broader toward the apex, or center, of the whorl (where the cochlea is smallest). Different regions of the basilar membrane vibrate according to the frequency of the sound wave conducted through the fluid in the cochlea. For these reasons, the fluid-filled cochlea detects different wave frequencies (pitches) at different regions of the membrane. When the sound waves in the cochlear fluid contact the basilar membrane, it flexes back and forth in a wave-like fashion. Above the basilar membrane is the **tectorial membrane**.

**Figure 27.14** In the human ear, sound waves cause the stapes to press against the oval window. Vibrations travel up the fluid-filled interior of the cochlea. The basilar membrane that lines the cochlea gets continuously thinner toward the apex of the cochlea. Different thicknesses of membrane vibrate in response to different frequencies of sound. Sound waves then exit through the round window. In the cross section of the cochlea (top right figure), note that in addition to the upper canal and lower canal, the cochlea also has a middle canal. The organ of Corti (bottom image) is the site of sound transduction. Movement of stereocilia on hair cells results in an action potential that travels along the auditory nerve.

Cochlear implants can restore hearing in people who have a nonfunctional cochlea. The implant consists of a microphone that picks up sound. A speech processor selects sounds in the range of human speech, and a transmitter converts these sounds to electrical impulses, which are then sent to the auditory nerve. Which of the following types of hearing loss would not be restored by a cochlear implant?

1. Hearing loss resulting from absence or loss of hair cells in the organ of Corti.
2. Hearing loss resulting from an abnormal auditory nerve.
3. Hearing loss resulting from fracture of the cochlea.
4. Hearing loss resulting from damage to bones of the middle ear.

Cochlear implants can restore hearing in people who have a nonfunctional cochlea. The implant consists of a microphone that picks up sound. A speech processor selects sounds in the range of human speech, and a transmitter converts these sounds to electrical impulses, which are then sent to the auditory nerve. Which of the following types of hearing loss would not be restored by a cochlear implant?

- a. Hearing loss resulting from absence or loss of hair cells in the organ of Corti.
- b. Hearing loss resulting from an abnormal auditory nerve.
- c. Hearing loss resulting from fracture of the cochlea.
- d. Hearing loss resulting from damage to bones of the middle ear.

The site of transduction is in the **organ of Corti** (spiral organ). It is composed of hair cells held in place above the basilar membrane like flowers projecting up from soil, with their exposed short, hair-like **stereocilia** contacting or embedded in the tectorial membrane above them. The inner hair cells are the primary auditory receptors and exist in a single row, numbering approximately 3,500. The stereocilia from inner hair cells extend into small dimples on the tectorial membrane's lower surface. The outer hair cells are arranged in three or four rows. They number approximately 12,000, and they function to fine tune incoming sound waves. The longer stereocilia that project from the outer hair cells actually attach to the tectorial membrane. All of the stereocilia are mechanoreceptors, and when bent by vibrations they respond by opening a gated ion channel (refer to [Figure 27.2](#)). As a result, the hair cell membrane is depolarized, and a signal is transmitted to the cochlear nerve. Intensity (volume) of sound is determined by how many hair cells at a particular location are stimulated.

The hair cells are arranged on the basilar membrane in an orderly way. The basilar membrane vibrates in different regions, according to the frequency of the sound waves impinging on it. Likewise, the hair cells that lay above it are most sensitive to a specific frequency of sound waves. Hair cells can respond to a small range of similar frequencies, but they require stimulation of greater intensity to fire at frequencies outside of their optimal range. The difference in response frequency between adjacent inner hair cells is about 0.2 percent. Compare that to adjacent piano strings, which are about six percent different. Place theory, which is the model for how biologists think pitch detection works in the human ear, states that high frequency sounds selectively vibrate the basilar membrane of the inner ear near the entrance port (the oval window). Lower frequencies travel farther along the membrane before causing appreciable excitation of the membrane. The basic pitch-determining mechanism is based on the location along the membrane where the hair cells are stimulated. The place theory is the first step toward an understanding of pitch perception. Considering the extreme pitch sensitivity of the human ear, it is thought that there must be some auditory “sharpening” mechanism to enhance the pitch resolution.

When sound waves produce fluid waves inside the cochlea, the basilar membrane flexes, bending the stereocilia that attach to the tectorial membrane. Their bending results in action potentials in the hair cells, and auditory information travels along the neural endings of the bipolar neurons of the hair cells (collectively, the auditory nerve) to the brain. When the hairs bend, they release an excitatory neurotransmitter at a synapse with a sensory neuron, which then conducts action potentials to the central nervous system. The cochlear branch of the vestibulocochlear cranial nerve sends information on hearing. The auditory system is very refined, and there is some modulation or “sharpening” built in. The brain can send signals back to the cochlea, resulting in a change of length in the outer hair cells, sharpening or dampening the hair cells' response to certain frequencies.

Watch an **animation** (<http://openstaxcollege.org/l/hearing>) of sound entering the outer ear, moving through the ear structure, stimulating cochlear nerve impulses, and eventually sending signals to the temporal lobe.

Imagine that your friend's pet dog ran off into the woods while she was hiking. After about 10 minutes while she still hiked, your friend whistled for her dog, who came running back to her. Explain how the dog was able to use your friend's whistling to find her, even though she had moved from the location at which the dog had last seen her.

- a. The dog was used to his master's whistling. This enabled the dog to determine where the sound was coming from.
- b. The dog was used to the hiking place. This enabled the dog to determine where the sound was coming from.
- c. The ears of the dog received the sounds at the same time. This enabled the dog to use the timing of sound reception in each ear to determine where the sound was coming from.
- d. The two ears of the dog received the sounds at slightly different times. This enabled the dog to use the timing of sound reception in each ear to determine where the sound was coming from.

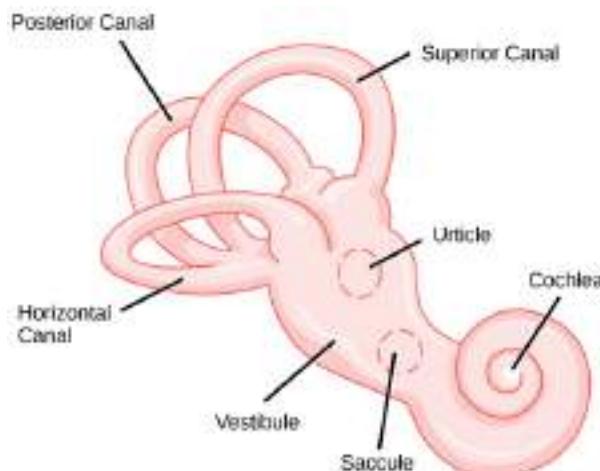

### ***Higher Processing***

The inner hair cells are most important for conveying auditory information to the brain. About 90 percent of the afferent neurons carry information from inner hair cells, with each hair cell synapsing with 10 or so neurons. Outer hair cells connect to only 10 percent of the afferent neurons, and each afferent neuron innervates many hair cells. The afferent, bipolar neurons that convey auditory information travel from the cochlea to the medulla, through the pons and midbrain in the brainstem, finally reaching the primary auditory cortex in the temporal lobe.

## **Vestibular Information**

The stimuli associated with the vestibular system are linear acceleration (gravity) and angular acceleration and deceleration. Gravity, acceleration, and deceleration are detected by evaluating the inertia on receptive cells in the vestibular system. Gravity is detected through head position. Angular acceleration and deceleration are expressed through turning or tilting of the head.

The vestibular system has some similarities with the auditory system. It utilizes hair cells just like the auditory system, but it excites them in different ways. There are five vestibular receptor organs in the inner ear: the utricle, the saccule, and three semicircular canals. Together, they make up what's known as the vestibular labyrinth that is shown in **Figure 27.15**. The utricle and saccule respond to acceleration in a straight line, such as gravity. The roughly 30,000 hair cells in the utricle and 16,000 hair cells in the saccule lie below a gelatinous layer, with their stereocilia projecting into the gelatin. Embedded in this gelatin are calcium carbonate crystals—like tiny rocks. When the head is tilted, the crystals continue to be pulled straight down by gravity, but the new angle of the head causes the gelatin to shift, thereby bending the stereocilia. The bending of the stereocilia stimulates the neurons, and they signal to the brain that the head is tilted, allowing the maintenance of balance. It is the vestibular branch of the vestibulocochlear cranial nerve that deals with balance.

**Figure 27.15** The structure of the vestibular labyrinth is shown. (credit: modification of work by NIH)

The fluid-filled **semicircular canals** are tubular loops set at oblique angles. They are arranged in three spatial planes. The base of each canal has a swelling that contains a cluster of hair cells. The hairs project into a gelatinous cap called the cupula and monitor angular acceleration and deceleration from rotation. They would be stimulated by driving your car around a corner, turning your head, or falling forward. One canal lies horizontally, while the other two lie at about 45 degree angles to the horizontal axis, as illustrated in [Figure 27.15](#). When the brain processes input from all three canals together, it can detect angular acceleration or deceleration in three dimensions. When the head turns, the fluid in the canals shifts, thereby bending stereocilia and sending signals to the brain. Upon cessation accelerating or decelerating—or just moving—the movement of the fluid within the canals slows or stops. For example, imagine holding a glass of water. When moving forward, water may splash backwards onto the hand, and when motion has stopped, water may splash forward onto the fingers. While in motion, the water settles in the glass and does not splash. Note that the canals are not sensitive to velocity itself, but to changes in velocity, so moving forward at 60mph with your eyes closed would not give the sensation of movement, but suddenly accelerating or braking would stimulate the receptors.

### **Higher Processing**

Hair cells from the utricle, saccule, and semicircular canals also communicate through bipolar neurons to the cochlear nucleus in the medulla. Cochlear neurons send descending projections to the spinal cord and ascending projections to the pons, thalamus, and cerebellum. Connections to the cerebellum are important for coordinated movements. There are also projections to the temporal cortex, which account for feelings of dizziness; projections to autonomic nervous system areas in the brainstem, which account for motion sickness; and projections to the primary somatosensory cortex, which monitors subjective measurements of the external world and self-movement. People with lesions in the vestibular area of the somatosensory cortex see vertical objects in the world as being tilted. Finally, the vestibular signals project to certain optic muscles to coordinate eye and head movements.

Click through this **interactive tutorial** ([http://openstaxcollege.org/l/ear\\_anatomy](http://openstaxcollege.org/l/ear_anatomy)) to review the parts of the ear and how they function to process sound.

You have trouble maintaining balance. Identify the part of your ear that has been damaged.

## 27.5 | Vision

In this section, you will explore the following questions:

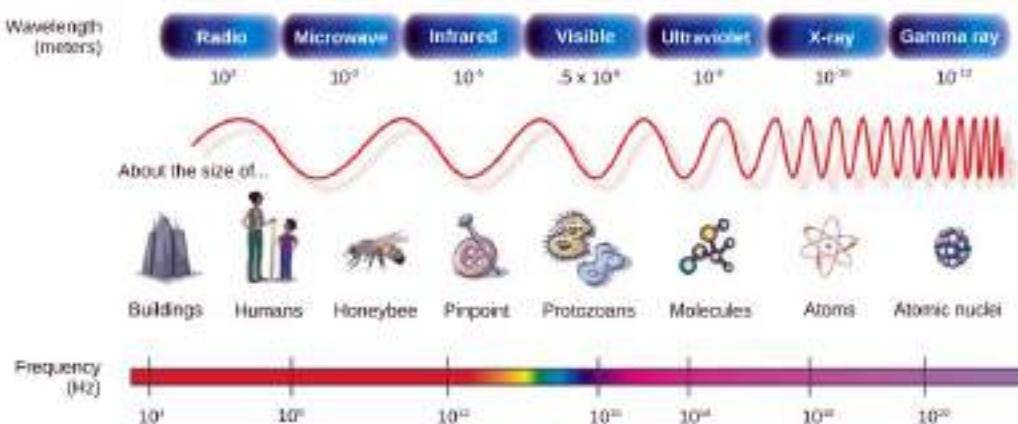

- How do electromagnetic waves differ from sound waves?
- What path does light take as it travels through the eye to the point of the optic nerve?
- What is tonic activity as it is manifested in photoreceptors in the retina?

**Vision** is the ability to detect light patterns from the outside environment and interpret them into images. Animals are bombarded with sensory information, and the sheer volume of visual information can be problematic. Fortunately, the visual systems of species have evolved to attend to the most-important stimuli. The importance of vision to humans is further substantiated by the fact that about one-third of the human cerebral cortex is dedicated to analyzing and perceiving visual information.

### Light

As with auditory stimuli, light travels in waves. The compression waves that compose sound must travel in a medium—a gas, a liquid, or a solid. In contrast, light is composed of electromagnetic waves and needs no medium; light can travel in a vacuum (**Figure 27.16**). The behavior of light can be discussed in terms of the behavior of waves and also in terms of the behavior of the fundamental unit of light—a packet of electromagnetic radiation called a photon. A glance at the electromagnetic spectrum shows that visible light for humans is just a small slice of the entire spectrum, which includes radiation that we cannot see as light because it is below the frequency of visible red light and above the frequency of visible violet light.

Certain variables are important when discussing perception of light. Wavelength (which varies inversely with frequency) manifests itself as hue. Light at the red end of the visible spectrum has longer wavelengths (and is lower frequency), while light at the violet end has shorter wavelengths (and is higher frequency). The wavelength of light is expressed in nanometers (nm); one nanometer is one billionth of a meter. Humans perceive light that ranges between approximately 380 nm and 740 nm. Some other animals, though, can detect wavelengths outside of the human range. For example, bees see near-ultraviolet light in order to locate nectar guides on flowers, and some non-avian reptiles sense infrared light (heat that prey gives off).

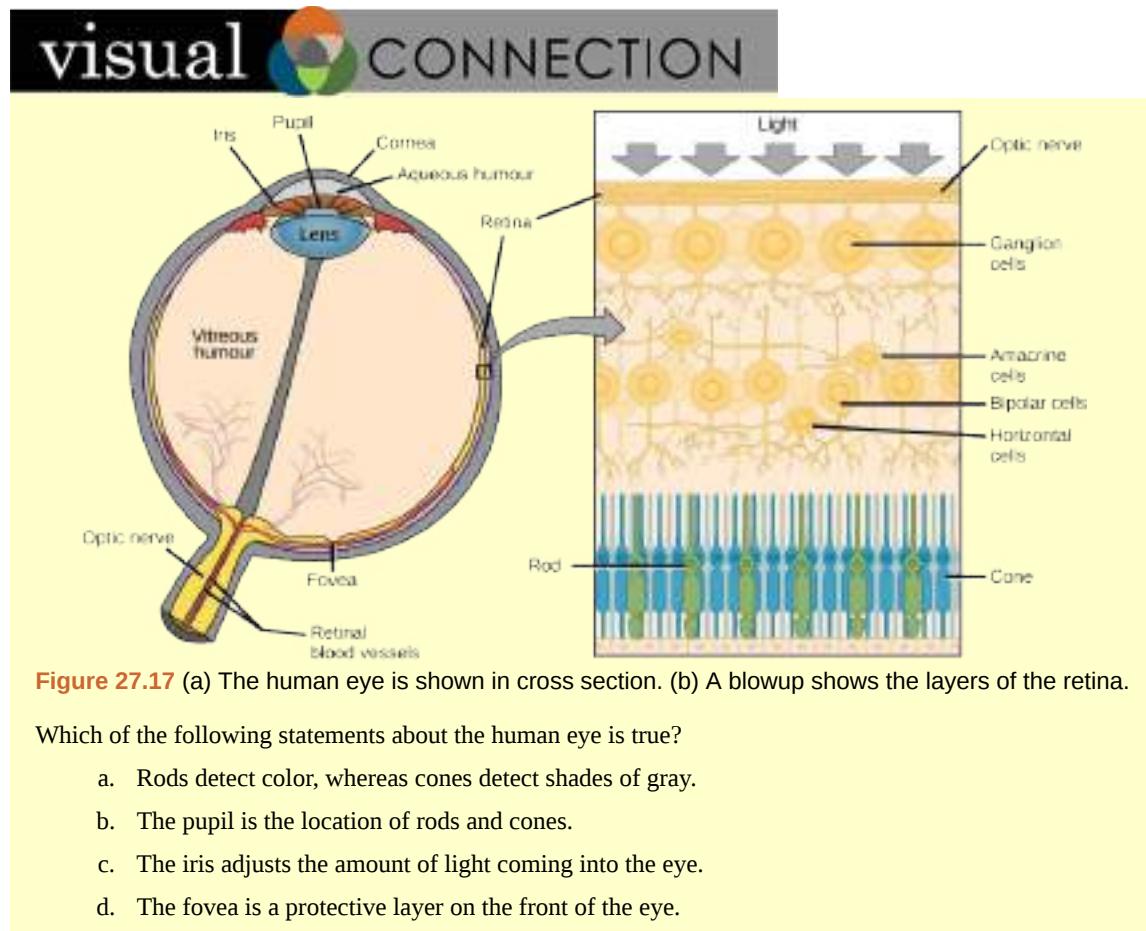

**Figure 27.16** In the electromagnetic spectrum, visible light lies between 380 nm and 740 nm. (credit: modification of work by NASA)

Wave amplitude is perceived as luminous intensity, or brightness. The standard unit of intensity of light is the **candela**, which is approximately the luminous intensity of a one common candle.

Light waves travel 299,792 km per second in a vacuum, (and somewhat slower in various media such as air and water), and those waves arrive at the eye as long (red), medium (green), and short (blue) waves. What is termed “white light” is light that is perceived as white by the human eye. This effect is produced by light that stimulates equally the color receptors in the human eye. The apparent color of an object is the color (or colors) that the object reflects. Thus a red object reflects the red wavelengths in mixed (white) light and absorbs all other wavelengths of light.

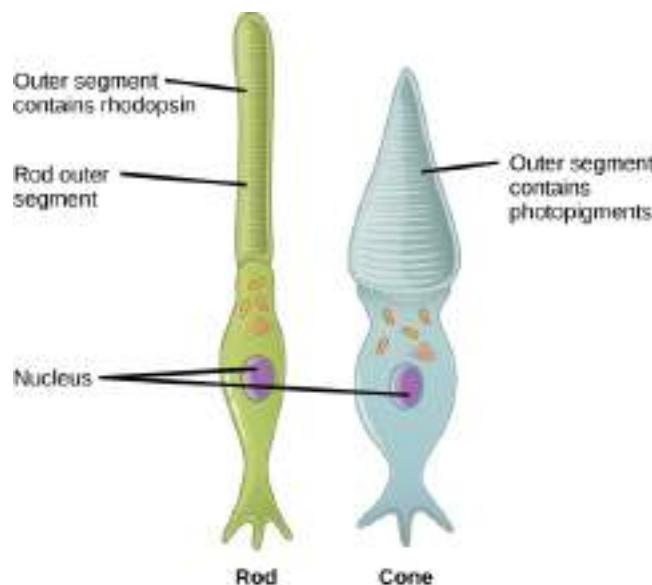

## Anatomy of the Eye

The photoreceptive cells of the eye, where transduction of light to nervous impulses occurs, are located in the **retina** (shown in **Figure 27.17**) on the inner surface of the back of the eye. But light does not impinge on the retina unaltered. It passes through other layers that process it so that it can be interpreted by the retina (**Figure 27.17b**). The **cornea**, the front transparent layer of the eye, and the crystalline **lens**, a transparent convex structure behind the cornea, both refract (bend) light to focus the image on the retina. The **iris**, which is conspicuous as the colored part of the eye, is a circular muscular ring lying between the lens and cornea that regulates the amount of light entering the eye. In conditions of high ambient light, the iris contracts, reducing the size of the pupil at its center. In conditions of low light, the iris relaxes and the pupil enlarges.

The main function of the lens is to focus light on the retina and fovea centralis. The lens is dynamic, focusing and re-focusing light as the eye rests on near and far objects in the visual field. The lens is operated by muscles that stretch it flat or allow it to thicken, changing the focal length of light coming through it to focus it sharply on the retina. With age comes the loss of the flexibility of the lens, and a form of farsightedness called **presbyopia** results. Presbyopia occurs because the image focuses behind the retina. Presbyopia is a deficit similar to a different type of farsightedness called **hyperopia** caused by an eyeball that is too short. For both defects, images in the distance are clear but images nearby are blurry. **Myopia** (nearsightedness) occurs when an eyeball is elongated and the image focus falls in front of the retina. In this case, images in the distance are blurry but images nearby are clear.

There are two types of photoreceptors in the retina: **rods** and **cones**, named for their general appearance as illustrated in **Figure 27.18**. Rods are strongly photosensitive and are located in the outer edges of the retina. They detect dim light and are used primarily for peripheral and nighttime vision. Cones are weakly photosensitive and are located near the center of the retina. They respond to bright light, and their primary role is in daytime, color vision.

**Figure 27.18** Rods and cones are photoreceptors in the retina. Rods respond in low light and can detect only shades of gray. Cones respond in intense light and are responsible for color vision.

The **fovea** is the region in the center back of the eye that is responsible for acute vision. The fovea has a high density of cones. When you bring your gaze to an object to examine it intently in bright light, the eyes orient so that the object's image falls on the fovea. However, when looking at a star in the night sky or other object in dim light, the object can be better viewed by the peripheral vision because it is the rods at the edges of the retina, rather than the cones at the center, that operate better in low light. In humans, cones far outnumber rods in the fovea.

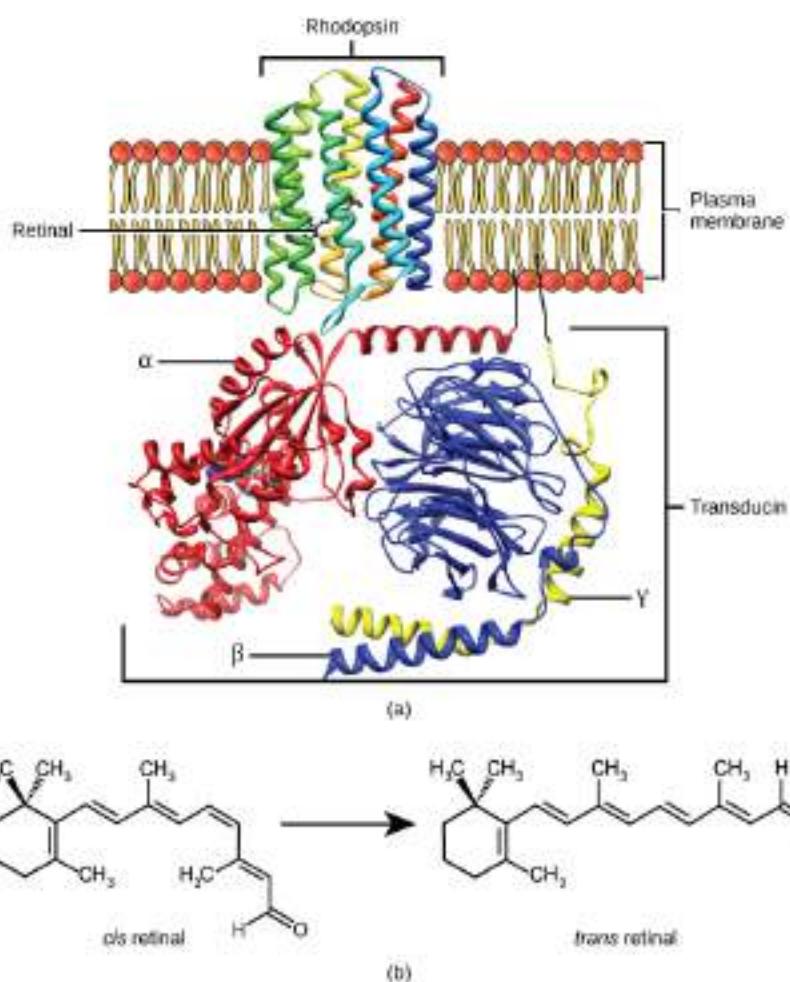

Review the **anatomical structure** ([http://openstaxcollege.org/l/eye\\_diagram](http://openstaxcollege.org/l/eye_diagram)) of the eye, clicking on each part to practice identification.

Identify the part of your eye that could be damaged if your eyes are incapable of focusing an image on the retina.

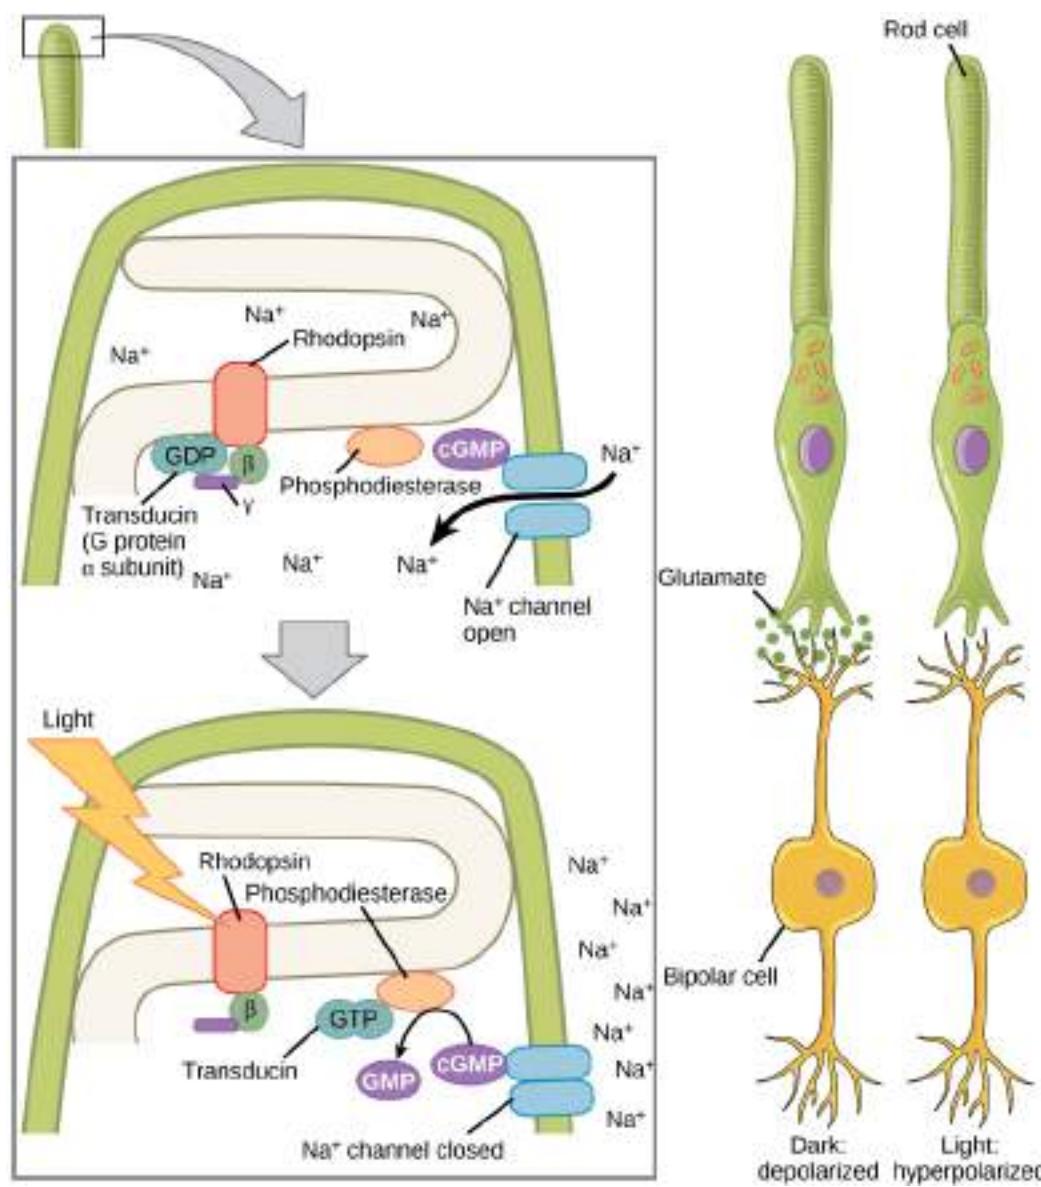

- lens
- iris
- rods
- cones

## Transduction of Light

The rods and cones are the site of transduction of light to a neural signal. Both rods and cones contain photopigments. In vertebrates, the main photopigment, **rhodopsin**, has two main parts (Figure 27.19): an opsin, which is a membrane protein (in the form of a cluster of  $\alpha$ -helices that span the membrane), and retinal—a molecule that absorbs light. When light hits a photoreceptor, it causes a shape change in the retinal, altering its structure from a bent (*cis*) form of the molecule to its linear (*trans*) isomer. This isomerization of retinal activates the rhodopsin, starting a cascade of events that ends with the closing of  $\text{Na}^+$  channels in the membrane of the photoreceptor. Thus, unlike most other sensory neurons (which become depolarized by exposure to a stimulus) visual receptors become hyperpolarized and thus driven away from threshold (Figure 27.20).

**Figure 27.19** (a) Rhodopsin, the photoreceptor in vertebrates, has two parts: the trans-membrane protein opsins, and retinal. When light strikes retinal, it changes shape from (b) a *cis* to a *trans* form. The signal is passed to a G-protein called transducin, triggering a series of downstream events.

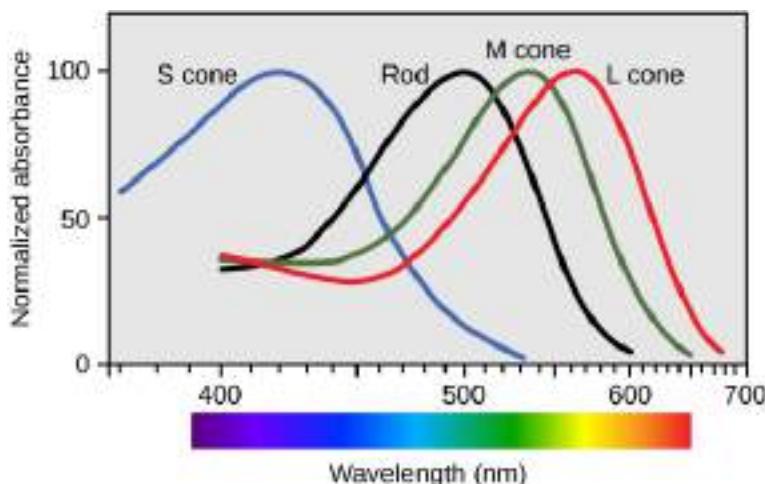

**Figure 27.20** When light strikes rhodopsin, the G-protein transducin is activated, which in turn activates phosphodiesterase. Phosphodiesterase converts cGMP to GMP, thereby closing sodium channels. As a result, the membrane becomes hyperpolarized. The hyperpolarized membrane does not release glutamate to the bipolar cell.

### Trichromatic Coding

There are three types of cones (with different photopsins), and they differ in the wavelength to which they are most responsive, as shown in **Figure 27.21**. Some cones are maximally responsive to short light waves of 420 nm, so they are called S cones ("S" for "short"); others respond maximally to waves of 530 nm (M cones, for "medium"); a third group responds maximally to light of longer wavelengths, at 560 nm (L, or "long" cones). With only one type of cone, color vision would not be possible, and a two-cone (dichromatic) system has limitations. Primates use a three-cone (trichromatic) system, resulting in full color vision.

The color we perceive is a result of the ratio of activity of our three types of cones. The colors of the visual spectrum, running from long-wavelength light to short, are red (700 nm), orange (600 nm), yellow (565 nm), green (497 nm), blue (470 nm), indigo (450 nm), and violet (425 nm). Humans have very sensitive perception of color and can distinguish about 500 levels of brightness, 200 different hues, and 20 steps of saturation, or about 2 million distinct colors.

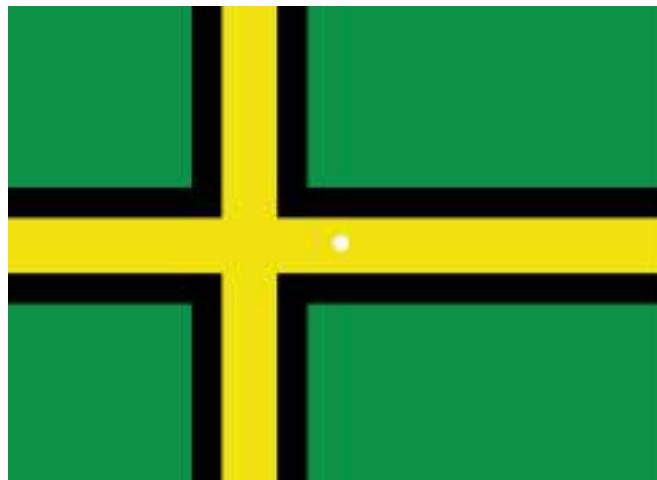

**Figure 27.21** Human rod cells and the different types of cone cells each have an optimal wavelength. However, there is considerable overlap in the wavelengths of light detected.

### Retinal Processing

Visual signals leave the cones and rods, travel to the bipolar cells, and then to ganglion cells. A large degree of processing of visual information occurs in the retina itself, before visual information is sent to the brain.

Photoreceptors in the retina continuously undergo **tonic activity**. That is, they are always slightly active even when not stimulated by light. In neurons that exhibit tonic activity, the absence of stimuli maintains a firing rate at a baseline; while some stimuli increase firing rate from the baseline, and other stimuli decrease firing rate. In the absence of light, the bipolar neurons that connect rods and cones to ganglion cells are continuously and actively inhibited by the rods and cones. Exposure of the retina to light hyperpolarizes the rods and cones and removes their inhibition of bipolar cells. The now active bipolar cells in turn stimulate the ganglion cells, which send action potentials along their axons (which leave the eye as the optic nerve). Thus, the visual system relies on change in retinal activity, rather than the absence or presence of activity, to encode visual signals for the brain. Sometimes horizontal cells carry signals from one rod or cone to other photoreceptors and to several bipolar cells. When a rod or cone stimulates a horizontal cell, the horizontal cell inhibits more distant photoreceptors and bipolar cells, creating lateral inhibition. This inhibition sharpens edges and enhances contrast in the images by making regions receiving light appear lighter and dark surroundings appear darker. Amacrine cells can distribute information from one bipolar cell to many ganglion cells.

You can demonstrate this using an easy demonstration to “trick” your retina and brain about the colors you are observing in your visual field. Look fixedly at **Figure 27.22** for about 45 seconds. Then quickly shift your gaze to a sheet of blank white paper or a white wall. You should see an afterimage of the Norwegian flag in its correct colors. At this point, close your eyes for a moment, then reopen them, looking again at the white paper or wall; the afterimage of the flag should continue to appear as red, white, and blue. What causes this? According to an explanation called opponent process theory, as you gazed fixedly at the green, black, and yellow flag, your retinal ganglion cells that respond positively to green, black, and yellow increased their firing dramatically. When you shifted your gaze to the neutral white ground, these ganglion cells abruptly decreased their activity and the brain interpreted this abrupt downshift as if the ganglion cells were responding now to their “opponent” colors: red, white, and blue, respectively, in the visual field. Once the ganglion cells return to their baseline activity state, the false perception of color will disappear.

**Figure 27.22** View this flag to understand how retinal processing works. Stare at the center of the flag (indicated by the white dot) for 45 seconds, and then quickly look at a white background, noticing how colors appear.

## Higher Processing

The myelinated axons of ganglion cells make up the optic nerves. Within the nerves, different axons carry different qualities of the visual signal. Some axons constitute the magnocellular (big cell) pathway, which carries information about form, movement, depth, and differences in brightness. Other axons constitute the parvocellular (small cell) pathway, which carries information on color and fine detail. Some visual information projects directly back into the brain, while other information crosses to the opposite side of the brain. This crossing of optical pathways produces the distinctive optic chiasma (Greek, for “crossing”) found at the base of the brain and allows us to coordinate information from both eyes.

Once in the brain, visual information is processed in several places, and its routes reflect the complexity and importance of visual information to humans and other animals. One route takes the signals to the thalamus, which serves as the routing station for all incoming sensory impulses except olfaction. In the thalamus, the magnocellular and parvocellular distinctions remain intact, and there are different layers of the thalamus dedicated to each. When visual signals leave the thalamus, they travel to the primary visual cortex at the rear of the brain. From the visual cortex, the visual signals travel in two directions. One stream that projects to the parietal lobe, in the side of the brain, carries magnocellular (“where”) information. A second stream projects to the temporal lobe and carries both magnocellular (“where”) and parvocellular (“what”) information.

Another important visual route is a pathway from the retina to the **superior colliculus** in the midbrain, where eye movements are coordinated and integrated with auditory information. Finally, there is the pathway from the retina to the **suprachiasmatic nucleus** (SCN) of the hypothalamus. The SCN is a cluster of cells that is considered to be the body’s internal clock, which controls our **circadian** (day-long) cycle. The SCN sends information to the pineal gland, which is important in sleep/wake patterns and annual cycles.

View this **interactive presentation** ([http://openstaxcollege.org/l/sense\\_of\\_sight](http://openstaxcollege.org/l/sense_of_sight)) to review what you have learned about how vision functions.

Explain how the cornea and sclera are anatomically similar and different.

- a. Both are part of the ciliary body. However, the cornea is composed of collagen and elastic fibers, whereas the sclera is composed of connective tissue with epithelia.
- b. Both are part of the ciliary body. However, the cornea is composed of connective tissue with epithelia, whereas the sclera is composed of collagen and elastic fibers.
- c. Both are part of the outer tunic. However, the cornea is composed of collagen and elastic fibers, whereas the sclera is composed of connective tissue with epithelia.
- d. Both are part of outer tunic. However, the cornea is composed of connective tissue with epithelia, whereas the sclera is composed of collagen and elastic fibers.

## KEY TERMS

**audition** sense of hearing

**basilar membrane** stiff structure in the cochlea that indirectly anchors auditory receptors

**bipolar neuron** neuron with two processes from the cell body, typically in opposite directions

**candela** (cd) unit of measurement of luminous intensity (brightness)

**circadian** describes a time cycle about one day in length

**cochlea** whorled structure that contains receptors for transduction of the mechanical wave into an electrical signal

**cone** weakly photosensitive, chromatic, cone-shaped neuron in the fovea of the retina that detects bright light and is used in daytime color vision

**cornea** transparent layer over the front of the eye that helps focus light waves

**fovea** region in the center of the retina with a high density of photoreceptors and which is responsible for acute vision

**free nerve ending** ending of an afferent neuron that lacks a specialized structure for detection of sensory stimuli; some respond to touch, pain, or temperature

**glabrous** describes the non-hairy skin found on palms and fingers, soles of feet, and lips of humans and other primates

**glomerulus** in the olfactory bulb, one of the two neural clusters that receives signals from one type of olfactory receptor

**Golgi tendon organ** muscular proprioceptive tension receptor that provides the sensory component of the Golgi tendon reflex

**gustation** sense of taste

**hyperopia** (also, farsightedness) visual defect in which the image focus falls behind the retina, thereby making images in the distance clear, but close-up images blurry

**incus** (also, anvil) second of the three bones of the middle ear

**inner ear** innermost part of the ear; consists of the cochlea and the vestibular system

**iris** pigmented, circular muscle at the front of the eye that regulates the amount of light entering the eye

**kinesthesia** sense of body movement

**labyrinth** bony, hollow structure that is the most internal part of the ear; contains the sites of transduction of auditory and vestibular information

**lens** transparent, convex structure behind the cornea that helps focus light waves on the retina

**malleus** (also, hammer) first of the three bones of the middle ear

**mechanoreceptor** sensory receptor modified to respond to mechanical disturbance such as being bent, touch, pressure, motion, and sound

**Meissner's corpuscle** (also, tactile corpuscle) encapsulated, rapidly-adapting mechanoreceptor in the skin that responds to light touch

**Merkel's disc** unencapsulated, slowly-adapting mechanoreceptor in the skin that responds to touch

**middle ear** part of the hearing apparatus that functions to transfer energy from the tympanum to the oval window of the inner ear

**muscle spindle** proprioceptive stretch receptor that lies within a muscle and that shortens the muscle to an optimal length

for efficient contraction

**myopia** (also, nearsightedness) visual defect in which the image focus falls in front of the retina, thereby making images in the distance blurry, but close-up images clear

**nociception** neural processing of noxious (such as damaging) stimuli

**odorant** airborne molecule that stimulates an olfactory receptor

**olfaction** sense of smell

**olfactory bulb** neural structure in the vertebrate brain that receives signals from olfactory receptors

**olfactory epithelium** specialized tissue in the nasal cavity where olfactory receptors are located

**olfactory receptor** dendrite of a specialized neuron

**organ of Corti** in the basilar membrane, the site of the transduction of sound, a mechanical wave, to a neural signal

**ossicle** one of the three bones of the middle ear

**outer ear** part of the ear that consists of the pinna, ear canal, and tympanum and which conducts sound waves into the middle ear

**oval window** thin diaphragm between the middle and inner ears that receives sound waves from contact with the stapes bone of the middle ear

**Pacinian corpuscle** encapsulated mechanoreceptor in the skin that responds to deep pressure and vibration

**papilla** one of the small bump-like projections from the tongue

**perception** individual interpretation of a sensation; a brain function

**pheromone** substance released by an animal that can affect the physiology or behavior of other animals

**pinna** cartilaginous outer ear

**presbyopia** visual defect in which the image focus falls behind the retina, thereby making images in the distance clear, but close-up images blurry; caused by age-based changes in the lens

**proprioception** sense of limb position; used to track kinesthesia

**pupil** small opening through which light enters

**reception** receipt of a signal (such as light or sound) by sensory receptors

**receptive field** region in space in which a stimulus can activate a given sensory receptor

**receptor potential** membrane potential in a sensory receptor in response to detection of a stimulus

**retina** layer of photoreceptive and supporting cells on the inner surface of the back of the eye

**rhodopsin** main photopigment in vertebrates

**rod** strongly photosensitive, achromatic, cylindrical neuron in the outer edges of the retina that detects dim light and is used in peripheral and nighttime vision

**Ruffini ending** (also, bulbous corpuscle) slowly-adapting mechanoreceptor in the skin that responds to skin stretch and joint position

**semicircular canal** one of three half-circular, fluid-filled tubes in the vestibular labyrinth that monitors angular acceleration and deceleration

**sensory receptor** specialized neuron or other cells associated with a neuron that is modified to receive specific sensory

input

**sensory transduction** conversion of a sensory stimulus into electrical energy in the nervous system by a change in the membrane potential

**stapes** (also, stirrup) third of the three bones of the middle ear

**stereocilia** in the auditory system, hair-like projections from hair cells that help detect sound waves

**superior colliculus** paired structure in the top of the midbrain, which manages eye movements and auditory integration

**suprachiasmatic nucleus** cluster of cells in the hypothalamus that plays a role in the circadian cycle

**tastant** food molecule that stimulates gustatory receptors

**taste bud** clusters of taste cells

**tectorial membrane** cochlear structure that lies above the hair cells and participates in the transduction of sound at the hair cells

**tonic activity** in a neuron, slight continuous activity while at rest

**tympanum** (also, tympanic membrane or ear drum) thin diaphragm between the outer and middle ears

**ultrasound** sound frequencies above the human detectable ceiling of approximately 20,000 Hz

**umami** one of the five basic tastes, which is described as “savory” and which may be largely the taste of L-glutamate

**vestibular sense** sense of spatial orientation and balance

**vision** sense of sight

## CHAPTER SUMMARY

### 27.1 Sensory Processes

A sensory activation occurs when a physical or chemical stimulus is processed into a neural signal (sensory transduction) by a sensory receptor. Perception is an individual interpretation of a sensation and is a brain function. Humans have special senses: olfaction, gustation, equilibrium, and hearing, plus the general senses of somatosensation.

Sensory receptors are either specialized cells associated with sensory neurons or the specialized ends of sensory neurons that are a part of the peripheral nervous system, and they are used to receive information about the environment (internal or external). Each sensory receptor is modified for the type of stimulus it detects. For example, neither gustatory receptors nor auditory receptors are sensitive to light. Each sensory receptor is responsive to stimuli within a specific region in space, which is known as that receptor's receptive field. The most fundamental function of a sensory system is the translation of a sensory signal to an electrical signal in the nervous system.

All sensory signals, except those from the olfactory system, enter the central nervous system and are routed to the thalamus. When the sensory signal exits the thalamus, it is conducted to the specific area of the cortex dedicated to processing that particular sense.

### 27.2 Somatosensation

Somatosensation includes all sensation received from the skin and mucous membranes, as well as from the limbs and joints. Somatosensation occurs all over the exterior of the body and at some interior locations as well, and a variety of receptor types, embedded in the skin and mucous membranes, play a role.

There are several types of specialized sensory receptors. Rapidly adapting free nerve endings detect nociception, hot and cold, and light touch. Slowly adapting, encapsulated Merkel's disks are found in fingertips and lips, and respond to light touch. Meissner's corpuscles, found in glabrous skin, are rapidly adapting, encapsulated receptors that detect touch, low-frequency vibration, and flutter. Ruffini endings are slowly adapting, encapsulated receptors that detect skin stretch, joint activity, and warmth. Hair receptors are rapidly adapting nerve endings wrapped around the base of hair follicles that detect hair movement and skin deflection. Finally, Pacinian corpuscles are encapsulated, rapidly adapting receptors that

detect transient pressure and high-frequency vibration.

### 27.3 Taste and Smell

There are five primary tastes in humans: sweet, sour, bitter, salty, and umami. Each taste has its own receptor type that responds only to that taste. Tastants enter the body and are dissolved in saliva. Taste cells are located within taste buds, which are found on three of the four types of papillae in the mouth.

Regarding olfaction, there are many thousands of odorants, but humans detect only about 10,000. Like taste receptors, olfactory receptors are each responsive to only one odorant. Odorants dissolve in nasal mucosa, where they excite their corresponding olfactory sensory cells. When these cells detect an odorant, they send their signals to the main olfactory bulb and then to other locations in the brain, including the olfactory cortex.

### 27.4 Hearing and Vestibular Sensation

Audition is important for territory defense, predation, predator defense, and communal exchanges. The vestibular system, which is not auditory, detects linear acceleration and angular acceleration and deceleration. Both the auditory system and vestibular system use hair cells as their receptors.

Auditory stimuli are sound waves. The sound wave energy reaches the outer ear (pinna, canal, tympanum), and vibrations of the tympanum send the energy to the middle ear. The middle ear bones shift and the stapes transfers mechanical energy to the oval window of the fluid-filled inner ear cochlea. Once in the cochlea, the energy causes the basilar membrane to flex, thereby bending the stereocilia on receptor hair cells. This activates the receptors, which send their auditory neural signals to the brain.

The vestibular system has five parts that work together to provide the sense of direction, thus helping to maintain balance. The utricle and saccule measure head orientation: their calcium carbonate crystals shift when the head is tilted, thereby activating hair cells. The semicircular canals work similarly, such that when the head is turned, the fluid in the canals bends stereocilia on hair cells. The vestibular hair cells also send signals to the thalamus and to somatosensory cortex, but also to the cerebellum, the structure above the brainstem that plays a large role in timing and coordination of movement.

### 27.5 Vision

Vision is the only photo responsive sense. Visible light travels in waves and is a very small slice of the electromagnetic radiation spectrum. Light waves differ based on their frequency (wavelength = hue) and amplitude (intensity = brightness).

In the vertebrate retina, there are two types of light receptors (photoreceptors): cones and rods. Cones, which are the source of color vision, exist in three forms—L, M, and S—and they are differentially sensitive to different wavelengths. Cones are located in the retina, along with the dim-light, achromatic receptors (rods). Cones are found in the fovea, the central region of the retina, whereas rods are found in the peripheral regions of the retina.

Visual signals travel from the eye over the axons of retinal ganglion cells, which make up the optic nerves. Ganglion cells come in several versions. Some ganglion cell axons carry information on form, movement, depth, and brightness, while other axons carry information on color and fine detail. Visual information is sent to the superior colliculi in the midbrain, where coordination of eye movements and integration of auditory information takes place. Visual information is also sent to the suprachiasmatic nucleus (SCN) of the hypothalamus, which plays a role in the circadian cycle.

## REVIEW QUESTIONS

1. \_\_\_\_\_ is a type of general sense in humans.
  - a. gustation
  - b. olfaction
  - c. proprioception
  - d. equilibrium
2. Suppose you burned your tongue and could not taste food for a day. Identify the sense affected.
3. State where perception occurs.
  - a. spinal cord
  - b. cerebral cortex
  - c. receptors
  - d. thalamus
4. If a person's cold receptors no longer convert cold

sensory signals into electrical signals, that person has a problem with \_\_\_\_.

- a. reception
- b. the receptive field
- c. perception
- d. transduction

**5.** What is the smallest difference in stimuli that can be detected?

- a. receptor potential
- b. sensory transduction
- c. just-noticeable difference
- d. perception

**6.** In peppers, spicy heat is rated in SHUs, where 0 is the least amount of spicy heat. If the just-noticeable difference (JND) of the ability to perceive difference in heat detection for an individual is 30%, which of the following represents the JND of two different peppers?

- a. 8,500 vs 11,000 SHU
- b. 4,050 vs 15,000 SHU
- c. 15,000 vs 18,000 SHU
- d. 10,500 vs 15,000 SHU

**7.** What is the role of sensory receptors in sensory perception?

- a. detection of specific stimuli
- b. sensation interpretation
- c. sending electrical signals to the cortex
- d. transmitting signals from the brain to the rest of the body

**8.** Which mechanoreceptors in the skin are unencapsulated?

- a. Merkel's disks
- b. Meissner's corpuscles
- c. Ruffini endings
- d. Pacinian corpuscles

**9.** If an individual is born without the ability to sense high-frequency vibrations, he may have been born with a mutation in a gene that codes for \_\_\_\_.

- a. Merkel's disks
- b. Meissner's corpuscles
- c. Ruffini endings
- d. Pacinian corpuscles

**10.** If you were to burn your epidermis, what receptor type would most likely burn?

- a. free nerve endings
- b. Ruffini endings
- c. Pacinian corpuscles
- d. Krause end bulbs

**11.** \_\_\_\_ are found only in \_\_\_\_ skin, and detect skin deflection.

- a. Meissner's corpuscles, hairy
- b. Ruffini endings, glabrous
- c. Pacinian corpuscles, glabrous
- d. hair receptors, hairy

**12.** To what does nociception respond?

- a. injured stimuli
- b. deep, fleeting pressure
- c. fine touch
- d. cold

**13.** Why do peppers, which contain capsaicin, taste "hot"?

- a. Capsaicin is corrosive and damages tissue.
- b. Capsaicin contains large quantities of heat that are released upon ingestion.
- c. Capsaicin and warm receptors open the same calcium channels.
- d. Capsaicin stimulates Krause end bulbs.

**14.** \_\_\_\_ are mechanoreceptors that facilitate proper gripping of objects.

- a. Merkel's disks
- b. Meissner's corpuscles
- c. Ruffini endings
- d. Pacinian corpuscles

**15.** How many different taste molecules can an individual taste cell detect?

- a. one
- b. five
- c. depends on the type of taste receptor
- d. depends on the part of the tongue

**16.** Describe how gustation and olfaction are similar.

- a. Both sense different stimuli in the environment.
- b. Both can have hundreds of millions of types of receptors.
- c. Both obtain stimuli from within the body.
- d. Signals from both are transmitted through the medulla.

**17.** \_\_\_\_ is the term for savoriness in food.

- a. gustation
  - b. tastants
  - c. umami
  - d. pheromone
- 18.** If an individual becomes poisoned from eating excessive amounts of spoiled food, what kind of receptors might they lack?
- a. bitter
  - b. sweet
  - c. umami
  - d. sour
- 19.** A typical dog has approximately how many times more olfactory receptors than a typical human?
- a. 2
  - b. 8
  - c. 83
  - d. 333
- 20.** Which of the following is true of dog olfaction?
- a. Most dogs have 4 billion olfactory receptors.
  - b. Bloodhounds have more receptors than humans, but humans have more receptors than most dogs.
  - c. Rabbits and most dogs have the same number of olfactory receptors.
  - d. Dogs bred for sense of smell can have four times more olfactory cells than most other dogs.
- 21.** Which of the following has the most taste receptors?
- a. fungiform papillae
  - b. circumvallate papillae
  - c. foliate papillae
  - d. filiform papillae
- 22.** In sound, pitch is measured in \_\_\_\_\_, and volume is measured in \_\_\_\_\_.
- a. decibels (dB), hertz (Hz)
  - b. decibels (dB), nanometers (nm)
  - c. nanometers (nm), decibels (dB)
  - d. hertz (Hz), decibels (dB)
- 23.** Identify the animal that would be affected by a 120,000 Hz sound.
- a. cat
  - b. bat
  - c. dolphin
  - d. dog
- 24.** Louder sounds have a \_\_\_\_\_ compared with softer sounds.
- a. greater amplitude
  - b. lower amplitude
  - c. greater frequency
  - d. lower frequency
- 25.** Which of the following is true of frequency?
- a. Frequency is heard as volume.
  - b. Louder sounds have a higher frequency.
  - c. Men hear higher frequencies than women.
  - d. Frequency is measured in number of sound waves per unit time.
- 26.** The \_\_\_\_\_ contains receptors for transduction of mechanical waves to produce electrical signals.
- a. tympanum
  - b. cochlea
  - c. pinna
  - d. stapes
- 27.** The \_\_\_\_\_ contains \_\_\_\_\_, which produces action potentials along the auditory nerve.
- a. incus, stapes
  - b. ear canal, tympanum
  - c. tympanum, oval window
  - d. organ of Corti, stereocilia
- 28.** Identify the structure that is found both in the auditory system and the vestibular system.
- a. basilar membrane
  - b. hair cells
  - c. semicircular canals
  - d. ossicles
- 29.** You are in a car that suddenly decelerates. Explain what happens inside the ear as the car comes to a stop.
- a. Fluid in the semicircular canals moves.
  - b. Stereocilia are bent.
  - c. Deceleration signals are sent to the brain.
  - d. Fluid in the semicircular canals stops moving.
- 30.** Of the following, identify the waves with the highest frequency.
- a. microwaves
  - b. ultraviolet rays
  - c. x-rays
  - d. gamma rays
- 31.** Of the following colors, identify the color associated with the shortest wavelength.

- a. red
  - b. yellow
  - c. green
  - d. blue
- 32.** Which of the following is true of light detection?
- a. Humans see most of the light spectrum.
  - b. Light signals can pass through a vacuum into the eye.
  - c. Decibels are used as the unit of wavelength.
  - d. Violet light has a longer wavelength than red light.
- 33.** The fovea is responsible for \_\_\_\_\_, because it has a high density of cones.
- a. night vision
  - b. nearsightedness
  - c. farsightedness
  - d. acute vision
- 34.** Explain why people over 55 often need reading glasses.
- a. Their cornea no longer focuses correctly.
  - b. Their lens no longer focuses correctly.
  - c. Their eyeball has elongated with age, causing images to focus in front of their retina.
  - d. Their retina has thinned with age, making vision more difficult.
- 35.** Where does some visual processing occur before information reaches the brain?
- a. cornea
  - b. lens
  - c. iris
  - d. retina
- 36.** A person catching a ball must coordinate her head and eyes. Identify the part of the brain that is helping to do this.
- a. hypothalamus
  - b. superior colliculus
  - c. thalamus
  - d. pineal gland

## CRITICAL THINKING QUESTIONS

- 37.** Which statement explains how the two types of sensory transduction differ?
- a. Receptors can respond to multiple stimuli, whereas free nerve endings are specialized cells that detect a specific stimulus.
  - b. Receptors are specialized cells that detect a specific stimulus, whereas free nerve endings can respond to multiple stimuli.
  - c. Receptors are similar for different stimuli, whereas free nerve endings are different for different stimuli.
  - d. Receptors are specialized cells that detect a specific stimulus, whereas free nerve endings can respond to pressure.
- 38.** Describe how the steps of sensory perception would be affected if a person sustains damage to axons that lead from sensory receptors to the central nervous system.
- 39.** Give an example of how Weber's law is applicable to a just-noticeable difference.
- a. A difference between 20 and 21 units of weight is more likely detectable than a difference between 1 and 2 units.
  - b. A difference between 1 and 2 units of weight is more likely detectable than a difference between 20 and 21 units.
  - c. A difference between 1 and 2 units of weight is more likely detectable than a difference between 2 and 4 units.
  - d. A difference between 20 and 21 units of weight is more likely detectable than a difference between 2 and 4 units.
- 40.** Humans have both special and general senses. Which

statement explains what both types of senses have in common?

- a. All types of senses undergo sensory transduction by converting a stimulus into a chemical signal via the central nervous system.
- b. All types of senses undergo sensory transduction by converting a stimulus into an electrical signal via the peripheral nervous system.
- c. All types of senses undergo sensory transduction by converting a stimulus into a chemical signal via the nervous system.
- d. All types of senses undergo sensory transduction by converting a stimulus into an electrical signal via the nervous system.

**41.** Explain why there are more Merkel's disks and Meissner's corpuscles in your fingertips than in your palms.

- a. These two types of thermoreceptors are used to detect warmth and cold which is necessary to maintain body temperature.
- b. These two types of mechanoreceptors are used to detect fine details necessary for many roles of fingertips but not palms such as typing.
- c. These two types of proprioceptors are used to detect fine details necessary for many roles of fingertips but not palms, such as typing.
- d. These two types of mechanoreceptors are used to detect fine details, which are necessary for many roles of fingertips as well as palms.

**42.** Explain what can be inferred about the relative sizes of the areas of cortex that process signals from skin not densely innervated with sensory receptors versus skin that is densely innervated with sensory receptors.

- a. Areas of the cortex that process signals from skin with fewer sensory receptors are likely to be larger than those having large numbers of sensory receptors.
- b. Areas of the cortex that process signals from skin with fewer sensory receptors are likely to be smaller than those having large numbers of sensory receptors.
- c. Areas of the cortex that process signals from skin with fewer sensory receptors and large numbers of sensory receptors will likely be the same.
- d. There is no relationship between the relative sizes of areas of cortex that process signals from skin and the sensory receptor numbers.

**43.** Explain why some people think that peppers are painful or hot, while other people do not find peppers painful or hot.

- a. Peppers contain capsaicin, which opens the same sodium channels as warm receptors. Excess stimulation gives the perception of pain. Thus people who can tolerate more heat find peppers to be less painful.
- b. Peppers contain capsaicin, which opens the same calcium channels as warm receptors. Excess stimulation gives the perception of pain. Thus people who can tolerate more heat find peppers to be less painful.
- c. Peppers contain quinine, which opens the same calcium channels as warm receptors. Excess stimulation gives the perception of pain. Thus people who can tolerate more heat find peppers to be less painful.
- d. Peppers contain quinine, which opens the same sodium channels as warm receptors. Excess stimulation gives the perception of pain. Thus people who can tolerate more heat find peppers to be less painful.

**44.** Discuss how the location of mechanoreceptors affect their ability to sense different stimuli.

- a. Merkel's disks and Meissner's corpuscles are found in specialized regions and detect the amount of stretch. Pacinian corpuscles and Ruffini endings are able to sense deeper touch, such as deeper pressure.
- b. Merkel's disks and Meissner's corpuscles are found deeper in the skin and are able to sense deeper touch, such as deeper pressure. Pacinian corpuscles and Ruffini endings are able to better detect fine touch.
- c. Merkel's disks and Meissner's corpuscles are found deeper in the skin and detect fine touch. Pacinian corpuscles and Ruffini endings are able to sense deeper touch, such as deeper pressure.
- d. Merkel's disks and Meissner's corpuscles are found in more upper parts of the skin and detect fine touch. Pacinian corpuscles and Ruffini endings are able to sense deeper touch, such as deeper pressure.

**45.** Explain what happens to the ability to perceive taste and smell as people age.

- a. All senses decline with age, most dramatically by age 50 and then continue to decline thereafter.
- b. All senses increase with age, most dramatically by age 50 and then continue to increase thereafter.
- c. All senses decline with age, most dramatically by age 50 and then increase thereafter.
- d. All senses increase with age, most dramatically by age 50 and then decline thereafter.

**46.** Predict a possible effect on an animal of not being able to perceive taste.

- a. The animal might not be able to eat food.
- b. The animal might not be able to eat sweet and unspoiled food.
- c. The animal might not be able to distinguish food that is bitter and sour.
- d. The animal might not be able to distinguish food that is dangerous, bitter, spoiled, sour or sweet.

**47.** If a young child goes missing, predict why a bloodhound and not a poodle would be used to find the child.

- a. Bloodhounds were bred to have a better sense of smell, and thus have fewer olfactory receptors and larger olfactory epithelia.
- b. Bloodhounds were bred to have a better sense of smell, and thus have more olfactory receptors and larger olfactory epithelia.
- c. Bloodhounds were bred to have a better sense of smell, and thus have more olfactory receptors and smaller olfactory epithelia.
- d. Bloodhounds were bred to have a better sense of smell, and thus have more olfactory bulbs and larger olfactory receptors.

**48.** Explain how pheromones differ from other odorants, from the perspective of the recipient of the signal.

- a. Pheromones are sent to the main olfactory bulb instead of the amygdala and are not consciously perceived.
- b. Pheromones are sent to the amygdala instead of the main olfactory bulb and are consciously perceived.
- c. Pheromones are sent to the amygdala instead of the main olfactory bulb and are not consciously perceived.
- d. Pheromones are sent to the main olfactory bulb instead of the amygdala and are consciously perceived.

**49.** You are sitting with a dog and a cat and decide to test a 50,000 Hz ringtone. Identify which of you is likely to respond to the sound and explain why.

- a. The human and dog will respond, because they can hear up to 50,000 Hz.
- b. The cat and dog will respond, because they can hear up to 50,000 Hz.
- c. Only the dog will respond, because they can hear up to 50,000 Hz.
- d. Only the cat will respond, because cats can hear up to 50,000 Hz.

**50.** You are having a debate with someone in a library. A librarian asks you to “speak softer.” What characteristic of

sound does the librarian want you to change and how can you change it?

- a. wavelength, by lowering the amplitude at which you are speaking
- b. amplitude, by lowering the frequency at which you are speaking
- c. frequency, by lowering the volume at which you are speaking
- d. amplitude, by lowering the volume at which you are speaking.

**51.** If an individual was born without the malleus in either ear, explain why they might have problems with hearing.

- a. Without the malleus and incus, the vibrations of the tympanum would not be able to reach the stapes and then be sent to the cochlea.
- b. Without the malleus and incus, the vibrations of the pinna would not be able to reach the stapes and then be sent to the cochlea.
- c. Without the malleus and incus, sound waves would not be collected by the tympanum.
- d. Without the malleus and incus, sound waves would not be collected by the pinna.

**52.** Explain how being on the moon, which has less gravity than Earth, might affect vestibular sensation and why.

- a. Vestibular sensation relies on gravity's effects on tiny crystals in the inner nostril; therefore, reduced gravity on the moon would likely impair vestibular sensation.
- b. Vestibular sensation relies on gravity's effects on huge crystals in the inner ear; therefore, reduced gravity on the moon would likely impair vestibular sensation.
- c. Vestibular sensation relies on gravity's effects on tiny crystals in the inner ear; therefore, reduced gravity on the moon would likely impair vestibular sensation.
- d. Vestibular sensation relies on gravity's effects on tiny crystals in the outer ear; therefore, reduced gravity on the moon would likely impair vestibular sensation.

**53.** Explain why you are unable to see the heat emitted by a cricket.

- Ultraviolet light includes heat emitted by prey organisms of reptiles which is outside the visual spectrum for humans because the wavelength is less than 380 nm.
- Infrared light includes heat emitted by prey organisms of reptiles which is outside the visual spectrum for humans because the wavelength is less than 380 nm.
- Infrared light includes heat emitted by prey organisms of reptiles, which is outside the visual spectrum for humans because the wavelength is more than 400 nm.
- Ultraviolet light includes heat emitted by prey organisms of reptiles, which is outside the visual spectrum for humans because the wavelength is more than 400 nm.

**54.** Explain what the color receptors in your eyes are perceiving if you see a white building.

- All of the color receptors in your eyes are equally stimulated when you see the color white.
- Both L and M cones are equally stimulated in your eyes when you see the color white.
- Only the S cones are stimulated in your eyes when you see the color white.
- L cones are stimulated strongly and S cones are weakly stimulated when you see the color white.

**55.** Discuss how the relationship between photoreceptors and bipolar cells is different from other sensory receptors and adjacent cells.

- Photoreceptors and bipolar cells are depolarized, whereas other sensory receptors typically remain polarized.
- Photoreceptors and bipolar cells are hyperpolarized, whereas other sensory receptors typically remain polarized.
- Photoreceptors and bipolar cells are depolarized, whereas other sensory receptors typically become hyperpolarized.
- Photoreceptors and bipolar cells are hyperpolarized, whereas other sensory receptors typically become depolarized.

**56.** Explain what happens once visual signals reach the visual cortex.

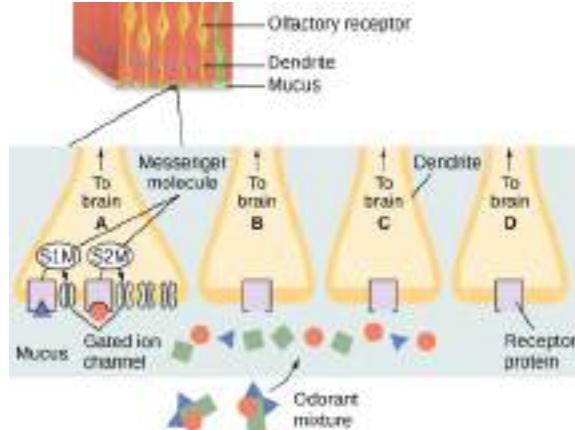

- Some signals go to the temporal lobe, which detects “where” information, and other signals go to the parietal lobe, which detects “where” and “what” signals.
- Some signals go to the parietal lobe, which detects “where” information, and other signals go to the temporal lobe, which detects “what” signals.
- Some signals go to the parietal lobe, which detects “where” and “what” information and other signals go to the temporal lobe, which also detects “where” and “what” signals.
- Some signals go to the parietal lobe, which detects “where” information, and other signals go to the temporal lobe, which detects “where” and “what” signals.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**57.** Odorants are mixtures of many different molecules. The complexity of the human sense of smell can be represented visually as a grid of 100 cells ( $10 \times 10$  grid) with each cell associated with a unique molecule-receptor pair. An odorant is detected when the brain integrates the signals generated by each molecule in the mixture.

Four olfactory sensors, each innervated by a nerve that transmits information to the brain as an action potential, are shown in the diagram at the right. Three of the sensors each respond to one of the three odor molecules in the geometric representation of the odorant mixture.

A. In the diagram the odorant-receptor pairing is imagined geometrically; a round peg fits in a round hold and a square peg does not. The receptors are located in the epidermal cell surface, shown in the drawing as a light gray line. **Create a geometric representation** by drawing receptors on the surfaces of the sensors that are activated by one of the molecules in the mixture. **Draw a geometric representation** of a fourth receptor surface that is not activated by a molecule in the odorant mixture.

**Figure 27.23**

In the receptor cell labeled A, two signaling molecules S1M and S2M are shown as are two types of gated ion channels; one that transports  $\text{Ca}^{2+}$  in response to S1M while generating S2M, and three that transport  $\text{Na}^+$  in response to S2M.

**B. Construct an explanation** of the mechanism for transmission of information when the odorant molecule is detected at receptor A using this signaling cascade. In your explanation include the role of positive feedback and the mechanism of the generation of an action potential.

Signal integration allows the brain to discriminate this particular odorant mixture from others using the time dependence in each signal. The sensitivity of an olfactory system increases as the number of unique receptors increases.

**C. Complete the following table to construct a mathematical representation** of sensitivity to the chemical landscape assuming that there are 100 unique odorant molecules. Use the following mathematic routine to determine the number of odors caused by groups of molecules selected from the 100 odorant molecules:

| Number, r, of odor-producing molecules in the odorant | Number of different odorants                    |
|-------------------------------------------------------|-------------------------------------------------|
| 3                                                     | $100 \cdot 99 \cdot 98 / (3 \cdot 2) = 161,700$ |
| 4                                                     |                                                 |
| 5                                                     |                                                 |
| 6                                                     |                                                 |
| 7                                                     |                                                 |

Table 27.2

$$\text{number of groups} = \frac{100!}{r!(100-r)!}$$

$$\text{where } n! = n \cdot (n-1) \cdot (n-2) \cdot (n-3) \dots \text{and } 0! = 1$$

Bushdid et al. (*Science*, 343, 2014) extended this model and then used human subjects to experimentally determine the number of unique odorant molecules that they could discriminate to obtain an estimate of 1.72 trillion different detectable smells.

Olfactory receptor proteins that recognize chemicals as odors are expressed in humans by approximately 400 different genes. This is the largest number of genes coding for a single function in the human genome (Nimura, *Human Genetics*, 4, 2009). Other mammals have an even greater diversity of olfactory receptors: roughly 800 and 1200 genes in dogs and rats, respectively. Some olfactory receptors are adapted for odorants in an aqueous environment and some are adapted for an air environment.

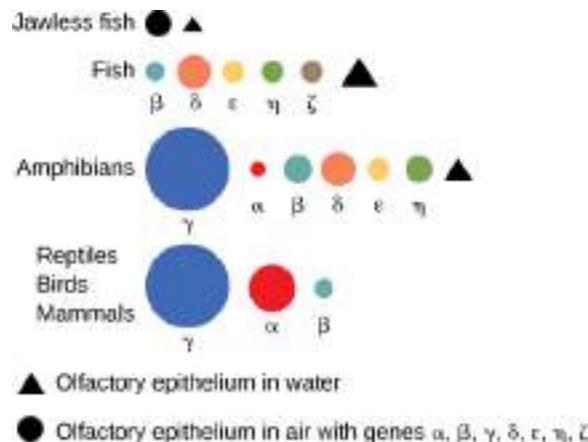

Figure 27.24

**D. Use the representation above, showing classes of genes within groups of organisms, to construct a representation** of the phylogenetic relationships among these groups. Annotate your representation to show gene additions and deletions. To your representation also add annotation that connects the phenotype to the environment.

**58.** When you get cold you may shiver. The shivering response is a reflex in which the hypothalamus in the brain integrates sensory input, comparing input against a temperature set point. When a threshold signal is detected, nerves of the somatic nervous system that innervate skeletal muscle are stimulated. The extension and contraction of muscle cells releases heat energy that elevates the body temperature.

**A. Construct a representation** of the information flow for the shivering response. Annotate your representation to include

- the sensory input
- signal transmission to the hypothalamus
- signal transmission from the hypothalamus to the somatic nervous system
- transmission to muscle tissue
- and output response.

Include in your annotation the negative feedback loop that is established.

**B. Shivering occurs when you have a fever even though your body temperature has not fallen. Identify** the component of the information flow represented above that can cause this effect and **describe** how the brain has integrated the immune system and nervous system to maintain homeostasis.

Thermogenesis from accelerated metabolism in adipose (fat) tissue is a non-shivering response to a cold stimulus. Using a neurotropic virus, investigators are able to trace the paths of nerves in animals. Neurons infected by virus can then be visualized by exposing the tissue to antibodies that can be stained or using dyes that fluoresce. Ryu and

co-workers (*Journal of Neuroscience*, 35, 2015) used this technique to demonstrate communication between nerves of the sympathetic nervous system and nerves of the sensory nervous system innervating thermoreceptors that are sensitive to hot and cold.

C. **Construct a representation** of information flow and annotate the representation with labels for

- signal input caused by low temperature
- signal transmission through nerves of the sensory

system

- transmission of signal from the sensory system to the sympathetic system
- transmission to adipose cells
- output response of cells.

Include in your annotation the negative feedback loop that is established.

# 28 | THE ENDOCRINE SYSTEM

**Figure 28.1** The process of amphibian metamorphosis, as seen in the tadpole-to-frog stages shown here, is driven by hormones. (credit "tadpole": modification of work by Brian Gratwicke)

## Chapter Outline

- 28.1: Types of Hormones**
- 28.2: How Hormones Work**
- 28.3: Regulation of Body Processes**
- 28.4: Regulation of Hormone Production**
- 28.5: Endocrine Glands**

## Introduction

An animal's endocrine system controls body processes through the production, secretion, and regulation of hormones, which serve as chemical "messengers" functioning in cellular and organ activity and, ultimately, maintaining the body's homeostasis. The endocrine system plays a role in growth, metabolism, and sexual development. In humans, common endocrine system diseases include thyroid disease and diabetes mellitus. In organisms that undergo metamorphosis, the process is controlled by the endocrine system. The transformation from tadpole to frog, for example, is complex and nuanced to adapt to specific environments and ecological circumstances.

The study of the endocrine system has led to many medical advances. Now scientists have discovered a hormone that mimics the effects of exercise by regulating metabolism and fighting insulin resistance.<sup>[1]</sup> You can read more about this exciting discovery at the [Science Daily website \(<http://openstaxcollege.org/l/32hormoneadv>\)](http://openstaxcollege.org/l/32hormoneadv).

## 28.1 | Types of Hormones

In this section, you will explore the following questions:

- What are the different types of hormones?
- What is the role of hormones in maintaining homeostasis?

## Connection for AP<sup>®</sup> Courses

Much information about the various organ systems of animals is not within the scope for AP<sup>®</sup>. The endocrine system, however, was selected for in-depth study because an animal's ability to detect, transmit and respond to information is critical

1. Lee, Changhan, Zeng, Jennifer, Drew, Brian G., Sallam, Tamer, Martin-Montalvo, Alejandro, Wan, Junxiang, Kim, Su-Jeong, Mehta, Hemal, Hevener, Andrea L., de Cabo, Rafael, Cohen, Pinchas. **The Mitochondrial-Derived Peptide MOTS-c Promotes Metabolic Homeostasis and Reduces Obesity and Insulin Resistance.** *Cell Metabolism*, 2015; 21 (3): 443 DOI:[10.1016/j.cmet.2015.02.009](https://doi.org/10.1016/j.cmet.2015.02.009)

to survival. The endocrine and nervous systems work together to maintain homeostasis and adjust physiological activity when external or internal environmental conditions change. The nervous system works by generating action potentials along neurons; the endocrine system uses chemical messengers called hormones that are released from glands, travel to target cells, and elicit a response by the target cell. For AP® you are not expected to memorize a laundry list of the various endocrine glands, their hormones, and the effects of each hormone. You should be able to interpret, however, a diagram that shows the activity of a hormonal signal. We will briefly describe a few of these examples in **How Hormones Work**.

There are three types of hormones classified based on molecular structure and properties. (We explored structure/function relationships at the molecular level in the chapter on Biological Macromolecules.) **Lipid-derived hormones** are lipid-soluble and can diffuse across cell membranes because they are non-polar. Most lipid hormones are derived from cholesterol; examples include steroids such as estrogen and testosterone. Because lipid hormones can diffuse across cell membranes, their receptors are located in the cytoplasm of target cells. The **amino acid-derived hormones** are relatively small molecules derived from the amino acids tyrosine and tryptophan; examples include epinephrine, norepinephrine, thyroxin, and melatonin. **Peptide hormones** such as oxytocin and growth hormone consist of polypeptide chains of amino acids. Because these hormones are water-soluble and insoluble in lipids, they cannot pass through the plasma membrane of cells; their receptors are found on the surface of the target cells.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 and Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>4.1</b> The student is able to explain the connection between the sequence and subcomponents of a biological polymer and its properties. |

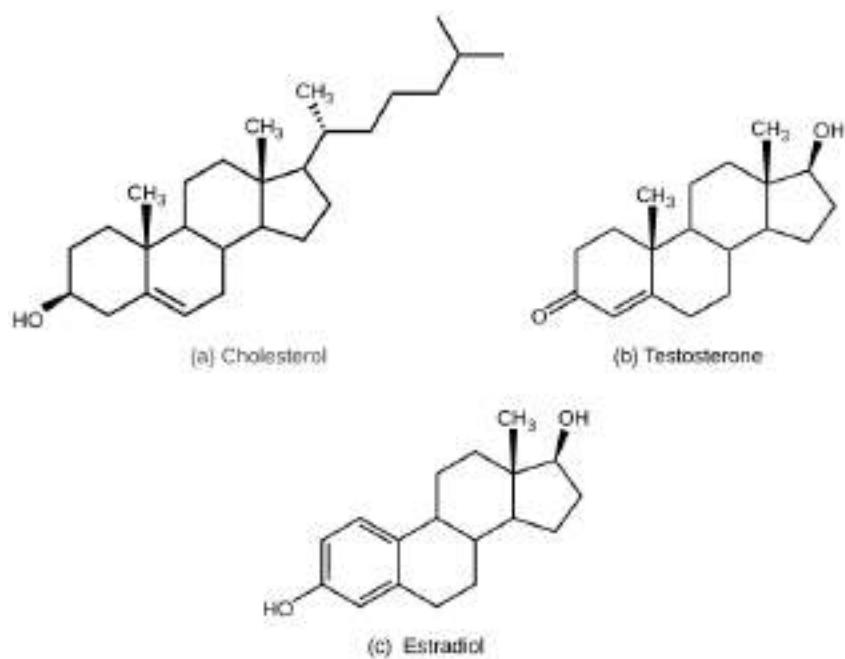

Maintaining homeostasis within the body requires the coordination of many different systems and organs. Communication between neighboring cells, and between cells and tissues in distant parts of the body, occurs through the release of chemicals called hormones. Hormones are released into body fluids (usually blood) that carry these chemicals to their target cells. At the target cells, which are cells that have a receptor for a signal or ligand from a signal cell, the hormones elicit a response. The cells, tissues, and organs that secrete hormones make up the endocrine system. Examples of glands of the endocrine system include the adrenal glands, which produce hormones such as epinephrine and norepinephrine that regulate responses to stress, and the thyroid gland, which produces thyroid hormones that regulate metabolic rates.

Although there are many different hormones in the human body, they can be divided into three classes based on their

chemical structure: lipid-derived, amino acid-derived, and peptide (peptide and proteins) hormones. One of the key distinguishing features of lipid-derived hormones is that they can diffuse across plasma membranes whereas the amino acid-derived and peptide hormones cannot.

## Lipid-Derived Hormones (or Lipid-soluble Hormones)

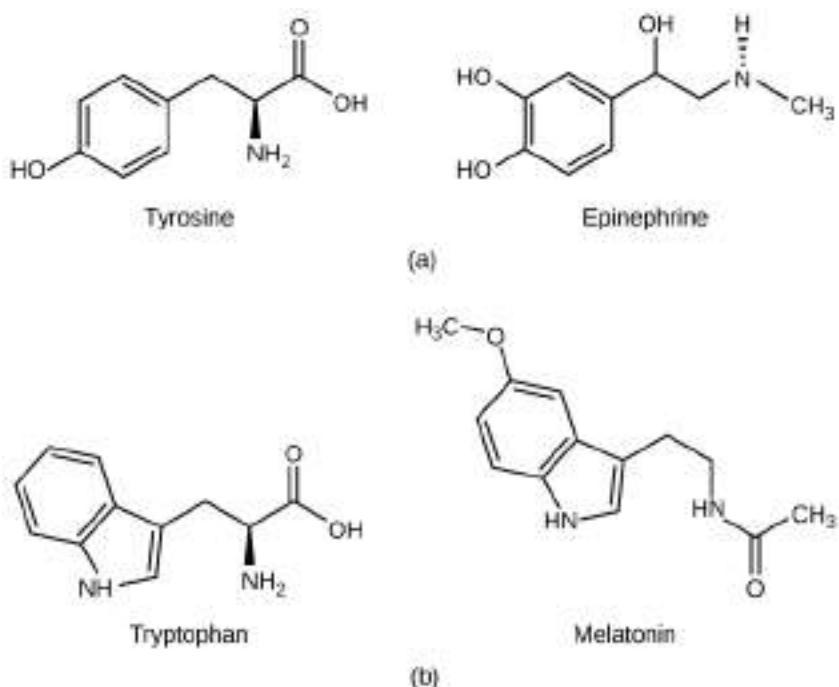

Most lipid hormones are derived from cholesterol and thus are structurally similar to it, as illustrated in [Figure 28.2](#). The primary class of lipid hormones in humans is the steroid hormones. Chemically, these hormones are usually ketones or alcohols; their chemical names will end in “-ol” for alcohols or “-one” for ketones. Examples of steroid hormones include estradiol, which is an **estrogen**, or female sex hormone, and testosterone, which is an androgen, or male sex hormone. These two hormones are released by the female and male reproductive organs, respectively. Other steroid hormones include aldosterone and cortisol, which are released by the adrenal glands along with some other types of androgens. Steroid hormones are insoluble in water, and they are transported by transport proteins in blood. As a result, they remain in circulation longer than peptide hormones. For example, cortisol has a half-life of 60 to 90 minutes, while epinephrine, an amino acid derived-hormone, has a half-life of approximately one minute.

**Figure 28.2** The structures shown here represent (a) cholesterol, plus the steroid hormones (b) testosterone and (c) estradiol.

## Amino Acid-Derived Hormones

The amino acid-derived hormones are relatively small molecules that are derived from the amino acids tyrosine and tryptophan, shown in [Figure 28.3](#). If a hormone is amino acid-derived, its chemical name will end in “-ine”. Examples of amino acid-derived hormones include epinephrine and norepinephrine, which are synthesized in the medulla of the adrenal glands, and thyroxine, which is produced by the thyroid gland. The pineal gland in the brain makes and secretes melatonin which regulates sleep cycles.

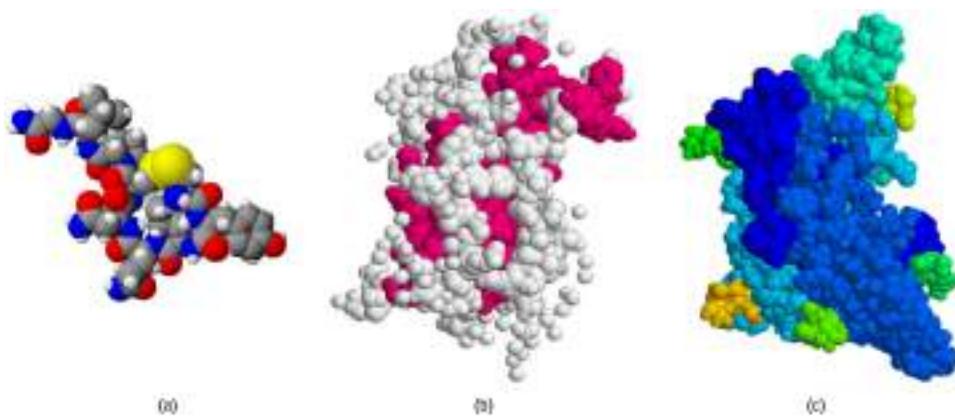

**Figure 28.3** (a) The hormone epinephrine, which triggers the fight-or-flight response, is derived from the amino acid tyrosine. (b) The hormone melatonin, which regulates circadian rhythms, is derived from the amino acid tryptophan.

## Peptide Hormones

The structure of peptide hormones is that of a polypeptide chain (chain of amino acids). The peptide hormones include molecules that are short polypeptide chains, such as antidiuretic hormone and oxytocin produced in the brain and released into the blood in the posterior pituitary gland. This class also includes small proteins, like growth hormones produced by the pituitary, and large glycoproteins such as follicle-stimulating hormone produced by the pituitary. **Figure 28.4** illustrates these peptide hormones.

Secreted peptides like insulin are stored within vesicles in the cells that synthesize them. They are then released in response to stimuli such as high blood glucose levels in the case of insulin. Amino acid-derived and polypeptide hormones are water-soluble and insoluble in lipids. These hormones cannot pass through plasma membranes of cells; therefore, their receptors are found on the surface of the target cells.

**Figure 28.4** The structures of peptide hormones (a) oxytocin, (b) growth hormone, and (c) follicle-stimulating hormone are shown. These peptide hormones are much larger than those derived from cholesterol or amino acids.

### Think About It

Although there are many different hormones in the human body, they can be classified based on their chemical structure. What one factor distinguishes them?

The logo for "career CONNECTION". The word "career" is in a white font with a graduation cap icon, and "CONNECTION" is in a white font.

### Endocrinologist

An endocrinologist is a medical doctor who specializes in treating disorders of the endocrine glands, hormone systems, and glucose and lipid metabolic pathways. An endocrine surgeon specializes in the surgical treatment of endocrine diseases and glands. Some of the diseases that are managed by endocrinologists: disorders of the pancreas (diabetes mellitus), disorders of the pituitary (gigantism, acromegaly, and pituitary dwarfism), disorders of the thyroid gland (goiter and Graves' disease), and disorders of the adrenal glands (Cushing's disease and Addison's disease).

Endocrinologists are required to assess patients and diagnose endocrine disorders through extensive use of laboratory tests. Many endocrine diseases are diagnosed using tests that stimulate or suppress endocrine organ functioning. Blood samples are then drawn to determine the effect of stimulating or suppressing an endocrine organ on the production of hormones. For example, to diagnose diabetes mellitus, patients are required to fast for 12 to 24 hours. They are then given a sugary drink, which stimulates the pancreas to produce insulin to decrease blood glucose levels. A blood sample is taken one to two hours after the sugar drink is consumed. If the pancreas is functioning properly, the blood glucose level will be within a normal range. Another example is the A1C test, which can be performed during blood screening. The A1C test measures average blood glucose levels over the past two to three months by examining how well the blood glucose is being managed over a long time.

Once a disease has been diagnosed, endocrinologists can prescribe lifestyle changes and/or medications to treat the disease. Some cases of diabetes mellitus can be managed by exercise, weight loss, and a healthy diet; in other cases, medications may be required to enhance insulin release. If the disease cannot be controlled by these means, the endocrinologist may prescribe insulin injections.

In addition to clinical practice, endocrinologists may also be involved in primary research and development activities. For example, ongoing islet transplant research is investigating how healthy pancreas islet cells may be transplanted into diabetic patients. Successful islet transplants may allow patients to stop taking insulin injections.

## 28.2 | How Hormones Work

In this section, you will explore the following questions:

- How do hormones work?
- What is the role of different types of hormone receptors?

### Connection for AP<sup>®</sup> Courses

Much of the information in this section is an application of the material we explored in the Cell Communication chapter about cell communication and signaling pathways. Hormones are chemical signals (ligands) that mediate changes in target cells by binding to specific receptors. Even though hormones released by endocrine glands can travel long distances through the blood and come into contact with many different cell types, they only affect cells that possess the necessary receptors.

Depending on the location of the receptor on the target cell and the chemical structure of the hormone, for example, whether or not it is lipid-soluble, hormones can mediate changes directly by binding to **intracellular hormone receptors** and modulating gene expression (transcription and translation), or indirectly by binding to cell surface receptors and simulating signaling pathways.

The hormone binds to its receptor like a key fits a lock. Because a lipid-derived hormone such as a steroid hormone can diffuse across the membrane of the target cell, they bind to intracellular receptors residing in the cytoplasm or in the nucleus. The cell signaling pathways induced by steroid hormones regulate specific genes by acting as transcription regulators. In turn, this affects the amount of protein produced. Lipid-derived hormones that are not steroids, for example, vitamin D and thyroxin, bind to receptors located in the nucleus of the target cell.

Because amino acid-derived hormones and polypeptide hormones are not lipid-soluble, they bind to **plasma membrane hormone receptors** located on the outer surface of the membrane. Unlike steroid hormones, they cannot act directly on DNA but activate a signaling pathway; this triggers intracellular activity and carries out the specific effects associated with the hormone. The hormone that initiated the signaling pathway is called a **first messenger**. In the case of the epinephrine signaling pathway, binding of the amino acid-derived hormone epinephrine to its receptor activates a G-protein which, in turn, activates cAMP, a second messenger, ultimately resulting in a cellular response such as the conversion of glycogen to glucose.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>3.36</b> The student is able to describe a model that expresses the key elements of signal transduction pathways by which a signal is converted to a cellular response. |

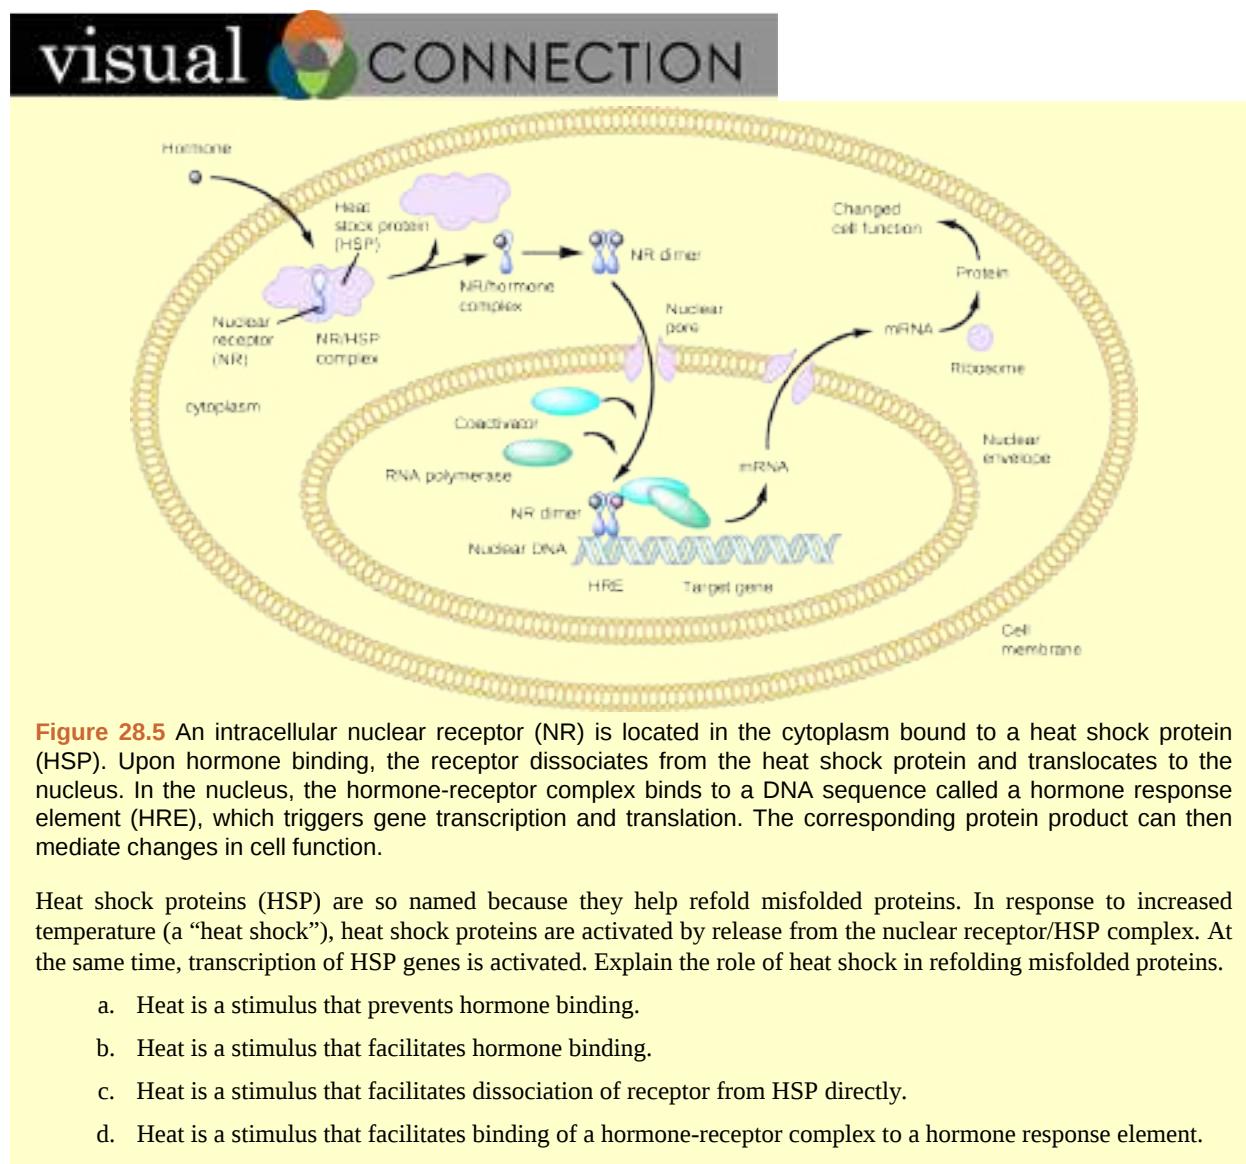

Hormones mediate changes in target cells by binding to specific **hormone receptors**. In this way, even though hormones circulate throughout the body and come into contact with many different cell types, they only affect cells that possess the necessary receptors. Receptors for a specific hormone may be found on many different cells or may be limited to a small number of specialized cells. For example, thyroid hormones act on many different tissue types, stimulating metabolic activity throughout the body. Cells can have many receptors for the same hormone but often also possess receptors for different types of hormones. The number of receptors that respond to a hormone determines the cell's sensitivity to that hormone, and the resulting cellular response. Additionally, the number of receptors that respond to a hormone can change over time, resulting in increased or decreased cell sensitivity. In **up-regulation**, the number of receptors increases in response to rising hormone levels, making the cell more sensitive to the hormone and allowing for more cellular activity. When the number of receptors decreases in response to rising hormone levels, called **down-regulation**, cellular activity is reduced.

Receptor binding alters cellular activity and results in an increase or decrease in normal body processes. Depending on the location of the protein receptor on the target cell and the chemical structure of the hormone, hormones can mediate changes directly by binding to intracellular hormone receptors and modulating gene transcription, or indirectly by binding to cell surface receptors and stimulating signaling pathways.

## Intracellular Hormone Receptors

Lipid-derived (soluble) hormones such as steroid hormones diffuse across the membranes of the endocrine cell. Once outside the cell, they bind to transport proteins that keep them soluble in the bloodstream. At the target cell, the hormones

are released from the carrier protein and diffuse across the lipid bilayer of the plasma membrane of cells. The steroid hormones pass through the plasma membrane of a target cell and adhere to intracellular receptors residing in the cytoplasm or in the nucleus. The cell signaling pathways induced by the steroid hormones regulate specific genes on the cell's DNA. The hormones and receptor complex act as transcription regulators by increasing or decreasing the synthesis of mRNA molecules of specific genes. This, in turn, determines the amount of corresponding protein that is synthesized by altering gene expression. This protein can be used either to change the structure of the cell or to produce enzymes that catalyze chemical reactions. In this way, the steroid hormone regulates specific cell processes as illustrated in **Figure 28.5**.

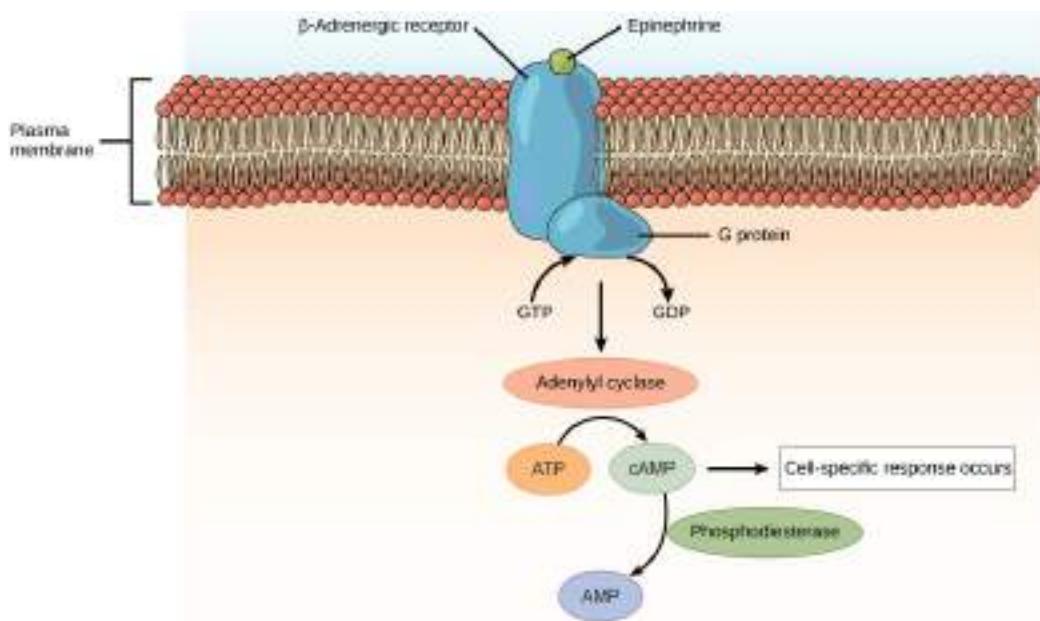

Other lipid-soluble hormones that are not steroid hormones, such as vitamin D and thyroxine, have receptors located in the nucleus. The hormones diffuse across both the plasma membrane and the nuclear envelope, then bind to receptors in the nucleus. The hormone-receptor complex stimulates transcription of specific genes.

## Plasma Membrane Hormone Receptors

Amino acid derived hormones and polypeptide hormones are not lipid-derived (lipid-soluble) and therefore cannot diffuse through the plasma membrane of cells. Lipid insoluble hormones bind to receptors on the outer surface of the plasma membrane, via plasma membrane hormone receptors. Unlike steroid hormones, lipid insoluble hormones do not directly affect the target cell because they cannot enter the cell and act directly on DNA. Binding of these hormones to a cell surface receptor results in activation of a signaling pathway; this triggers intracellular activity and carries out the specific effects

associated with the hormone. In this way, nothing passes through the cell membrane; the hormone that binds at the surface remains at the surface of the cell while the intracellular product remains inside the cell. The hormone that initiates the signaling pathway is called a first messenger, which activates a second messenger in the cytoplasm, as illustrated in **Figure 28.6**.

**Figure 28.6** The amino acid-derived hormones epinephrine and norepinephrine bind to beta-adrenergic receptors on the plasma membrane of cells. Hormone binding to receptor activates a G-protein, which in turn activates adenylyl cyclase, converting ATP to cAMP. cAMP is a second messenger that mediates a cell-specific response. An enzyme called phosphodiesterase breaks down cAMP, terminating the signal.

One very important second messenger is cyclic AMP (cAMP). When a hormone binds to its membrane receptor, a **G-protein** that is associated with the receptor is activated; G-proteins are proteins separate from receptors that are found in the cell membrane. When a hormone is not bound to the receptor, the G-protein is inactive and is bound to guanosine diphosphate, or GDP. When a hormone binds to the receptor, the G-protein is activated by binding guanosine triphosphate, or GTP, in place of GDP. After binding, GTP is hydrolysed by the G-protein into GDP and becomes inactive.

The activated G-protein in turn activates a membrane-bound enzyme called **adenylyl cyclase**. Adenylyl cyclase catalyzes the conversion of ATP to cAMP. cAMP, in turn, activates a group of proteins called protein kinases, which transfer a phosphate group from ATP to a substrate molecule in a process called phosphorylation. The phosphorylation of a substrate molecule changes its structural orientation, thereby activating it. These activated molecules can then mediate changes in cellular processes.

The effect of a hormone is amplified as the signaling pathway progresses. The binding of a hormone at a single receptor causes the activation of many G-proteins, which activates adenylyl cyclase. Each molecule of adenylyl cyclase then triggers the formation of many molecules of cAMP. Further amplification occurs as protein kinases, once activated by cAMP, can catalyze many reactions. In this way, a small amount of hormone can trigger the formation of a large amount of cellular product. To stop hormone activity, cAMP is deactivated by the cytoplasmic enzyme **phosphodiesterase**, or PDE. PDE is always present in the cell and breaks down cAMP to control hormone activity, preventing overproduction of cellular products.

The specific response of a cell to a lipid insoluble hormone depends on the type of receptors that are present on the cell membrane and the substrate molecules present in the cell cytoplasm. Cellular responses to hormone binding of a receptor include altering membrane permeability and metabolic pathways, stimulating synthesis of proteins and enzymes, and activating hormone release.

### Activity

Create a representation to describe how a lipid-soluble hormone and a peptide hormone activate different cellular responses in a target cell.

## 28.3 | Regulation of Body Processes

In this section, you will explore the following questions:

- How do hormones regulate the excretory system?
- What roles do hormones play in the reproductive system?
- How do hormones regulate metabolism?
- What is the role of hormones in different diseases?

### Connection for AP® Courses

The majority of information in this section is illustrative for AP®. You do not need to memorize a list of hormones and their effects on different body processes. However, if provided with a diagram showing the activity of a specific hormone, you should be able to interpret the diagram. This section specifically describes how different hormones affect the excretory system, the reproductive system, metabolism, blood calcium concentrations, growth, and the stress response. Disorders such as diabetes can arise from both the underproduction and overproduction of hormones. It is helpful to take a look at a couple of these examples of hormone activity.

Blood glucose (sugar) levels vary widely over the course of a day as periods of food consumption alternate with periods of fasting. Insulin and glucagon are two primary hormones responsible for maintaining the homeostasis of blood glucose levels. When the blood glucose level is high, beta cells of the pancreas secrete insulin, enhancing the rate of glucose uptake from the blood and utilization by target cells, such as the use of glucose for ATP production. When the blood glucose level is low, alpha cells of the pancreas secrete glucagon, stimulating the breakdown of glycogen to glucose.

A second example is hormonal regulation of the male and female reproductive systems (see the Animal Reproduction and Development chapter). Regulation requires the action of several hormones produced by the pituitary gland, the adrenal cortex, and the gonads. During puberty in both males and females, the hypothalamus produces gonadotropin-releasing hormone (GnRH), which stimulates the production and release of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) from the anterior pituitary gland. These hormones regulate the testes in males and ovaries in females. In males, FSH stimulates the maturation of sperm cells; LH stimulates the production of the sex hormones or androgens such as testosterone. (Anabolic steroids, a form of testosterone, have been associated with performance boosting in professional athletes.) In females, FSH stimulates the development of egg cells (ova); LH also plays a role in the development of ova, induction of ovulation, and stimulation of estradiol and progesterone production by the ovaries. Estradiol and progesterone are steroid hormones that regulate the menstrual cycle, among other functions. (Birth control pills designed to prevent ovulation contain fluctuating levels of these hormones.)

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

#### Big Idea 3

Living systems store, retrieve, transmit and respond to information essential to life processes.

Hormones have a wide range of effects and modulate many different body processes. The key regulatory processes that will be examined here are those affecting the excretory system, the reproductive system, metabolism, blood calcium concentrations, growth, and the stress response.

## Hormonal Regulation of the Excretory System

Maintaining a proper water balance in the body is important to avoid dehydration or over-hydration (hyponatremia). The water concentration of the body is monitored by **osmoreceptors** in the hypothalamus, which detect the concentration of electrolytes in the extracellular fluid. The concentration of electrolytes in the blood rises when there is water loss caused by excessive perspiration, inadequate water intake, or low blood volume due to blood loss. An increase in blood electrolyte levels results in a neuronal signal being sent from the osmoreceptors in hypothalamic nuclei. The pituitary gland has two components: anterior and posterior. The anterior pituitary is composed of glandular cells that secrete protein hormones. The posterior pituitary is an extension of the hypothalamus. It is composed largely of neurons that are continuous with the hypothalamus.

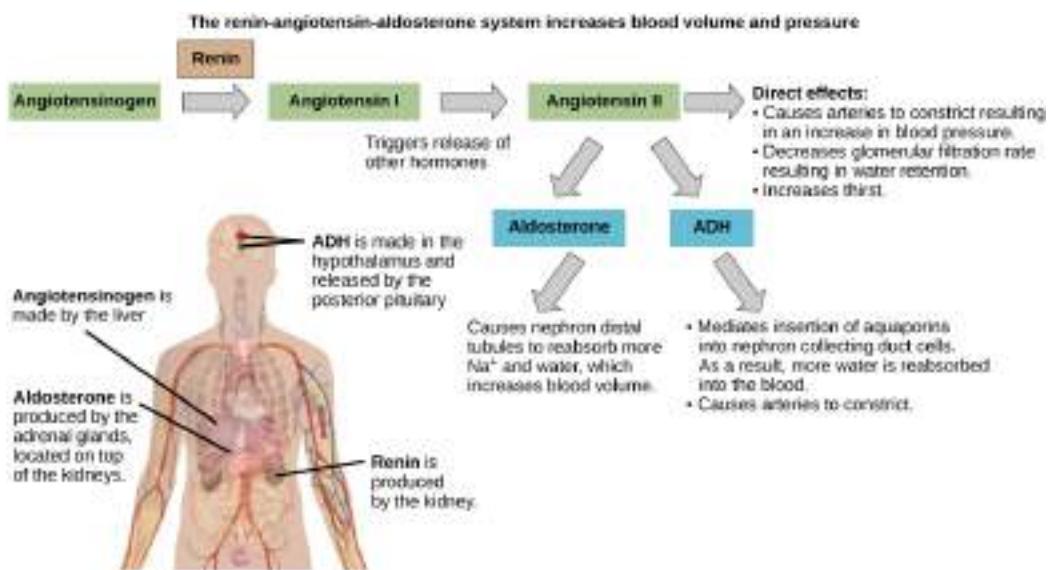

The hypothalamus produces a polypeptide hormone known as **antidiuretic hormone (ADH)**, which is transported to and released from the posterior pituitary gland. The principal action of ADH is to regulate the amount of water excreted by the kidneys. As ADH (which is also known as vasopressin) causes direct water reabsorption from the kidney tubules, salts and

wastes are concentrated in what will eventually be excreted as urine. The hypothalamus controls the mechanisms of ADH secretion, either by regulating blood volume or the concentration of water in the blood. Dehydration or physiological stress can cause an increase of osmolarity above 300 mOsm/L, which in turn, raises ADH secretion and water will be retained, causing an increase in blood pressure. ADH travels in the bloodstream to the kidneys. Once at the kidneys, ADH changes the kidneys to become more permeable to water by stimulating the temporary insertion of water channels, aquaporins, into the kidney tubules. Water moves out of the kidney tubules through the aquaporins, reducing urine volume. The water is reabsorbed into the capillaries, lowering blood osmolarity back toward normal. As blood osmolarity decreases, a negative feedback mechanism reduces osmoreceptor activity in the hypothalamus, and ADH secretion is reduced. ADH release can be reduced by certain substances, including alcohol, which can cause increased urine production and dehydration.

Chronic underproduction of ADH or a mutation in the ADH receptor results in **diabetes insipidus**. If the posterior pituitary does not release enough ADH, water cannot be retained by the kidneys and is lost as urine. This causes increased thirst, but water taken in is lost again and must be continually consumed. If the condition is not severe, dehydration may not occur, but severe cases can lead to electrolyte imbalances due to dehydration.

Another hormone responsible for maintaining electrolyte concentrations in extracellular fluids is **aldosterone**, a steroid hormone that is produced by the adrenal cortex. In contrast to ADH, which promotes the reabsorption of water to maintain proper water balance, aldosterone maintains proper water balance by enhancing  $\text{Na}^+$  reabsorption and  $\text{K}^+$  secretion from extracellular fluid of the cells in kidney tubules. Because it is produced in the cortex of the adrenal gland and affects the concentrations of minerals  $\text{Na}^+$  and  $\text{K}^+$ , aldosterone is referred to as a **mineralocorticoid**, a corticosteroid that affects ion and water balance. Aldosterone release is stimulated by a decrease in blood sodium levels, blood volume, or blood pressure, or an increase in blood potassium levels. It also prevents the loss of  $\text{Na}^+$  from sweat, saliva, and gastric juice. The reabsorption of  $\text{Na}^+$  also results in the osmotic reabsorption of water, which alters blood volume and blood pressure.

Aldosterone production can be stimulated by low blood pressure, which triggers a sequence of chemical release, as illustrated in **Figure 28.7**. When blood pressure drops, the renin-angiotensin-aldosterone system (RAAS) is activated. Cells in the juxtaglomerular apparatus, which regulates the functions of the nephrons of the kidney, detect this and release **renin**. Renin, an enzyme, circulates in the blood and reacts with a plasma protein produced by the liver called angiotensinogen. When angiotensinogen is cleaved by renin, it produces angiotensin I, which is then converted into angiotensin II in the lungs. Angiotensin II functions as a hormone and then causes the release of the hormone aldosterone by the adrenal cortex, resulting in increased  $\text{Na}^+$  reabsorption, water retention, and an increase in blood pressure. Angiotensin II in addition to being a potent vasoconstrictor also causes an increase in ADH and increased thirst, both of which help to raise blood pressure.

**Figure 28.7** ADH and aldosterone increase blood pressure and volume. Angiotensin II stimulates release of these hormones. Angiotensin II, in turn, is formed when renin cleaves angiotensinogen. (credit: modification of work by Mikael Häggström)

## Hormonal Regulation of the Reproductive System

Regulation of the reproductive system is a process that requires the action of hormones from the pituitary gland, the adrenal cortex, and the gonads. During puberty in both males and females, the hypothalamus produces gonadotropin-releasing hormone (GnRH), which stimulates the production and release of **follicle-stimulating hormone (FSH)** and luteinizing

hormone (LH) from the anterior pituitary gland. These hormones regulate the gonads (testes in males and ovaries in females) and therefore are called **gonadotropins**. In both males and females, FSH stimulates gamete production and LH stimulates production of hormones by the gonads. An increase in gonad hormone levels inhibits GnRH production through a negative feedback loop.

### ***Regulation of the Male Reproductive System***

In males, FSH stimulates the maturation of sperm cells. FSH production is inhibited by the hormone inhibin, which is released by the testes. LH stimulates production of the sex hormones (**androgens**) by the interstitial cells of the testes and therefore is also called interstitial cell-stimulating hormone.

The most widely known androgen in males is testosterone. Testosterone promotes the production of sperm and masculine characteristics. The adrenal cortex also produces small amounts of testosterone precursor, although the role of this additional hormone production is not fully understood.

## everyday CONNECTION

### The Dangers of Synthetic Hormones

**Figure 28.8** Professional baseball player Jason Giambi publicly admitted to, and apologized for, his use of anabolic steroids supplied by a trainer. (credit: Bryce Edwards)

Some athletes attempt to boost their performance by using artificial hormones that enhance muscle performance. Anabolic steroids, a form of the male sex hormone testosterone, are one of the most widely known performance-enhancing drugs. Steroids are used to help build muscle mass. Other hormones that are used to enhance athletic performance include erythropoietin, which triggers the production of red blood cells, and human growth hormone, which can help in building muscle mass. Most performance enhancing drugs are illegal for non-medical purposes. They are also banned by many national and international governing bodies, including many amateur and major league sports' associations.

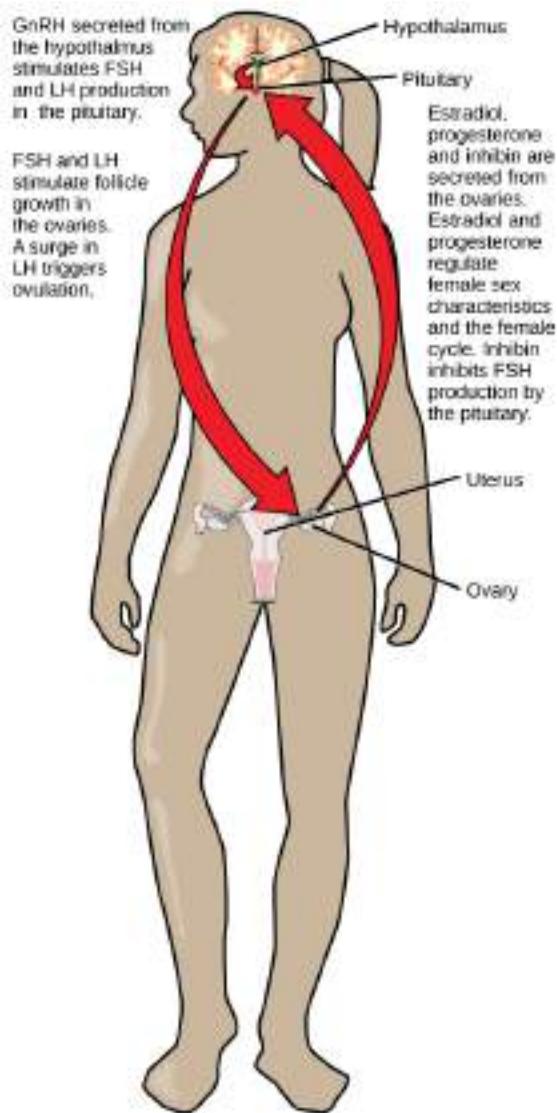

The side effects of synthetic hormones are often significant and non-reversible, and in some cases, fatal. Androgens produce several complications such as liver dysfunctions prostate gland enlargement, difficulty urinating, premature closure of epiphyseal cartilages, testicular atrophy, infertility, and immune system depression. The physiological strain caused by these substances is often greater than what the body can handle, leading to unpredictable and dangerous effects and linking their use to heart attacks, strokes, and impaired cardiac function.

Erythropoietin stimulates red blood cell production and thus increases the amount of oxygen supplied to muscles and, consequently, endurance. Explain why erythropoietin might be potentially dangerous if taken to enhance athletic performance.

- a. Erythropoietin increases blood viscosity, which makes it difficult for blood to circulate within the body.
- b. Erythropoietin decreases blood viscosity, which makes it difficult for blood to circulate within the body.
- c. Erythropoietin increases the activity of anorexigenic neurons, which makes it difficult for blood to circulate within the body.
- d. Erythropoietin increases blood viscosity, which reduces hunger and promotes a feeling of satiety.

### **Regulation of the Female Reproductive System**

In females, FSH stimulates development of egg cells, called ova, which develop in structures called follicles. Follicle cells produce the hormone inhibin, which inhibits FSH production. LH also plays a role in the development of ova, induction of ovulation, and stimulation of estradiol and progesterone production by the ovaries, as illustrated in **Figure 28.9**. Estradiol and progesterone are steroid hormones that prepare the body for pregnancy. Estradiol produces secondary sex characteristics in females, while both estradiol and progesterone regulate the menstrual cycle.

**Figure 28.9** Hormonal regulation of the female reproductive system involves hormones from the hypothalamus, pituitary, and ovaries.

In addition to producing FSH and LH, the anterior portion of the pituitary gland also produces the hormone **prolactin (PRL)** in females. Prolactin stimulates the production of milk by the mammary glands following childbirth. Prolactin levels are regulated by the hypothalamic hormones **prolactin-releasing hormone (PRH)** and **prolactin-inhibiting hormone (PIH)**, which is now known to be dopamine. PRH stimulates the release of prolactin and PIH inhibits it.

The posterior pituitary releases the hormone **oxytocin**, which stimulates uterine contractions during childbirth. The uterine smooth muscles are not very sensitive to oxytocin until late in pregnancy when the number of oxytocin receptors in the uterus peaks. Stretching of tissues in the uterus and cervix stimulates oxytocin release during childbirth. Contractions increase in intensity as blood levels of oxytocin rise via a positive feedback mechanism until the birth is complete. Oxytocin also stimulates the contraction of myoepithelial cells around the milk-producing mammary glands. As these cells contract, milk is forced from the secretory alveoli into milk ducts and is ejected from the breasts in milk ejection (“let-down”) reflex. Oxytocin release is stimulated by the suckling of an infant, which triggers the synthesis of oxytocin in the hypothalamus and its release into circulation at the posterior pituitary.

## Hormonal Regulation of Metabolism

Blood glucose levels vary widely over the course of a day as periods of food consumption alternate with periods of fasting. Insulin and glucagon are the two hormones primarily responsible for maintaining homeostasis of blood glucose levels. Additional regulation is mediated by the thyroid hormones.

### Regulation of Blood Glucose Levels by Insulin and Glucagon

Cells of the body require nutrients in order to function, and these nutrients are obtained through feeding. In order to manage nutrient intake, storing excess intake and utilizing reserves when necessary, the body uses hormones to moderate energy stores. **Insulin** is produced by the beta cells of the pancreas, which are stimulated to release insulin as blood glucose levels rise (for example, after a meal is consumed). Insulin lowers blood glucose levels by enhancing the rate of glucose uptake and utilization by target cells, which use glucose for ATP production. It also stimulates the liver to convert glucose to glycogen, which is then stored by cells for later use. Insulin also increases glucose transport into certain cells, such as muscle cells and the liver. This results from an insulin-mediated increase in the number of glucose transporter proteins in cell membranes, which remove glucose from circulation by facilitated diffusion. As insulin binds to its target cell via insulin receptors and signal transduction, it triggers the cell to incorporate glucose transport proteins into its membrane. This allows glucose to enter the cell, where it can be used as an energy source. However, this does not occur in all cells: some cells, including those in the kidneys and brain, can access glucose without the use of insulin. Insulin also stimulates the conversion of glucose to fat in adipocytes and the synthesis of proteins. These actions mediated by insulin cause blood glucose concentrations to fall, called a hypoglycemic “low sugar” effect, which inhibits further insulin release from beta cells through a negative feedback loop.

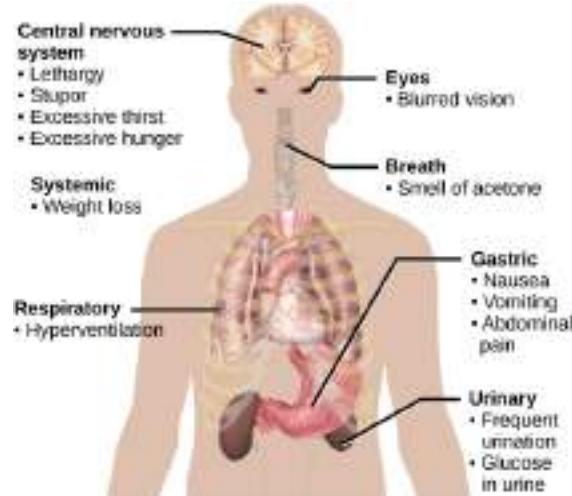

This **animation** (<http://openstaxcollege.org/l/insulin>) describe the role of insulin and the pancreas in diabetes.

Describe why Type 1 diabetes is considered an autoimmune disease.

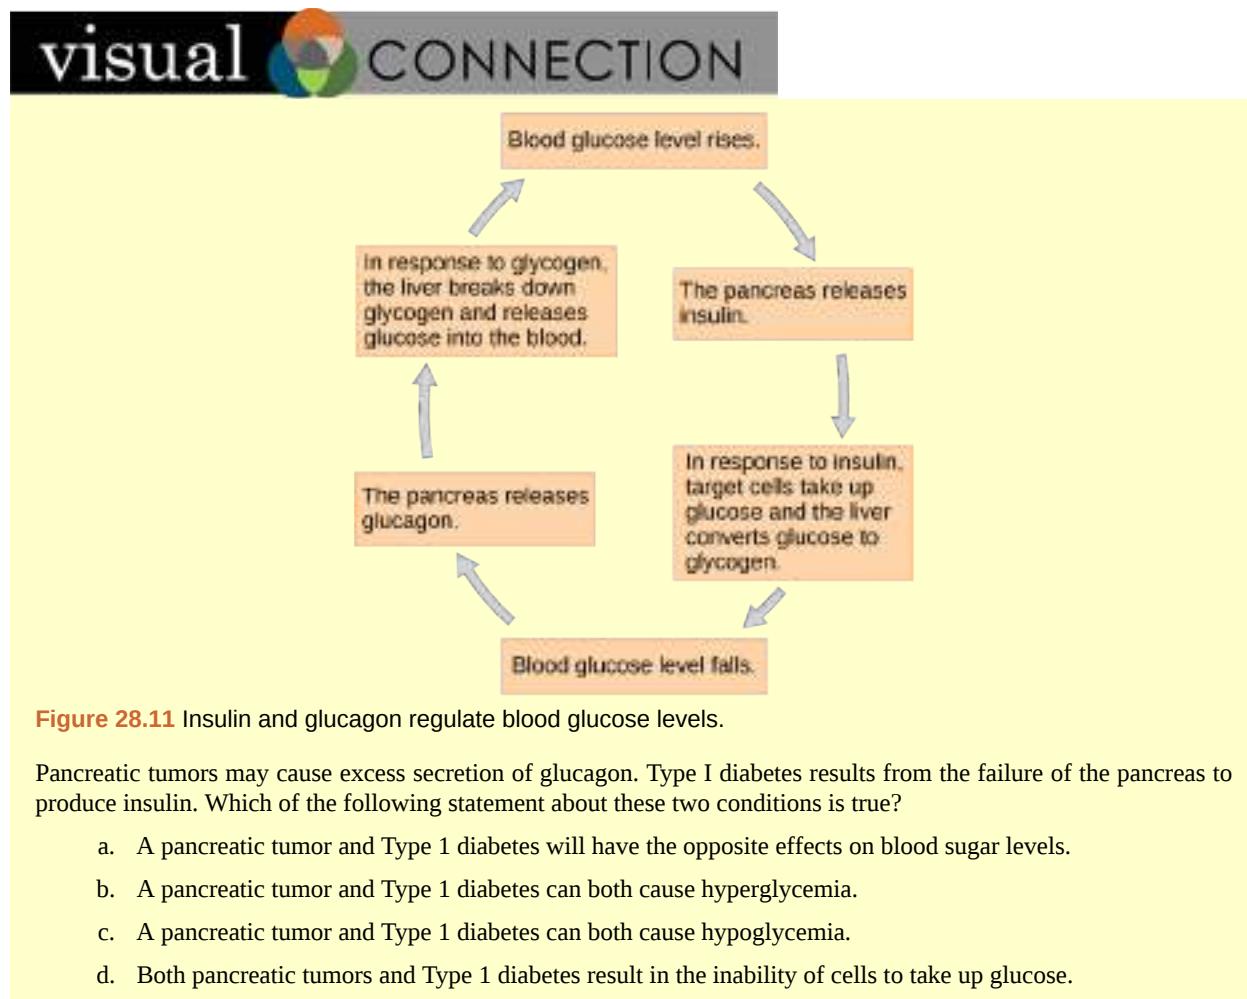

- The immune system attacks the hypothalamus, which prevents thyroxine production to regulate blood glucose.
- The immune system attacks cells of the pituitary gland, which prevents insulin production to regulate blood glucose.
- The immune system attacks beta cells of the pancreas, which prevents insulin production to regulate blood glucose.
- The immune system attacks beta cells of the pancreas, which prevents insulin production to regulate growth.

Impaired insulin function can lead to a condition called **diabetes mellitus**, the main symptoms of which are illustrated in **Figure 28.10**. This can be caused by low levels of insulin production by the beta cells of the pancreas, or by reduced sensitivity of tissue cells to insulin. This prevents glucose from being absorbed by cells, causing high levels of blood glucose, or **hyperglycemia** (high sugar). High blood glucose levels make it difficult for the kidneys to recover all the glucose from nascent urine, resulting in glucose being lost in urine. High glucose levels also result in less water being reabsorbed by the kidneys, causing high amounts of urine to be produced; this may result in dehydration. Over time, high blood glucose levels can cause nerve damage to the eyes and peripheral body tissues, as well as damage to the kidneys and cardiovascular system. Oversecretion of insulin can cause **hypoglycemia**, low blood glucose levels. This causes insufficient glucose availability to cells, often leading to muscle weakness, and can sometimes cause unconsciousness or death if left untreated.

**Figure 28.10** The main symptoms of diabetes are shown. (credit: modification of work by Mikael Häggström)

When blood glucose levels decline below normal levels, for example between meals or when glucose is utilized rapidly during exercise, the hormone **glucagon** is released from the alpha cells of the pancreas. Glucagon raises blood glucose levels, eliciting what is called a hyperglycemic effect, by stimulating the breakdown of glycogen to glucose in skeletal muscle cells and liver cells in a process called **glycogenolysis**. Glucose can then be utilized as energy by muscle cells and released into circulation by the liver cells. Glucagon also stimulates absorption of amino acids from the blood by the liver, which then converts them to glucose. This process of glucose synthesis is called **gluconeogenesis**. Glucagon also stimulates adipose cells to release fatty acids into the blood. These actions mediated by glucagon result in an increase in blood glucose levels to normal homeostatic levels. Rising blood glucose levels inhibit further glucagon release by the pancreas via a negative feedback mechanism. In this way, insulin and glucagon work together to maintain homeostatic glucose levels, as shown in **Figure 28.11**.

**Figure 28.11** Insulin and glucagon regulate blood glucose levels.

Pancreatic tumors may cause excess secretion of glucagon. Type I diabetes results from the failure of the pancreas to produce insulin. Which of the following statement about these two conditions is true?

- A pancreatic tumor and Type 1 diabetes will have the opposite effects on blood sugar levels.
- A pancreatic tumor and Type 1 diabetes can both cause hyperglycemia.
- A pancreatic tumor and Type 1 diabetes can both cause hypoglycemia.
- Both pancreatic tumors and Type 1 diabetes result in the inability of cells to take up glucose.

### Regulation of Blood Glucose Levels by Thyroid Hormones

The basal metabolic rate, which is the amount of calories required by the body at rest, is determined by two hormones produced by the thyroid gland: **thyroxine**, also known as tetraiodothyronine or T<sub>4</sub>, and **triiodothyronine**, also known as T<sub>3</sub>. These hormones affect nearly every cell in the body except for the adult brain, uterus, testes, blood cells, and spleen. They are transported across the plasma membrane of target cells and bind to receptors on the mitochondria resulting in increased ATP production. In the nucleus, T<sub>3</sub> and T<sub>4</sub> activate genes involved in energy production and glucose oxidation. This results in increased rates of metabolism and body heat production, which is known as the hormone's calorigenic effect.

T<sub>3</sub> and T<sub>4</sub> release from the thyroid gland is stimulated by **thyroid-stimulating hormone (TSH)**, which is produced by the anterior pituitary. TSH binding at the receptors of the follicle of the thyroid triggers the production of T<sub>3</sub> and T<sub>4</sub> from a glycoprotein called **thyroglobulin**. Thyroglobulin is present in the follicles of the thyroid, and is converted into thyroid hormones with the addition of iodine. Iodine is formed from iodide ions that are actively transported into the thyroid follicle from the bloodstream. A peroxidase enzyme then attaches the iodine to the tyrosine amino acid found in thyroglobulin. T<sub>3</sub> has three iodine ions attached, while T<sub>4</sub> has four iodine ions attached. T<sub>3</sub> and T<sub>4</sub> are then released into the bloodstream, with T<sub>4</sub> being released in much greater amounts than T<sub>3</sub>. As T<sub>3</sub> is more active than T<sub>4</sub> and is responsible for most of the effects of thyroid hormones, tissues of the body convert T<sub>4</sub> to T<sub>3</sub> by the removal of an iodine ion. Most of the released T<sub>3</sub> and T<sub>4</sub> becomes attached to transport proteins in the bloodstream and is unable to cross the plasma membrane of cells. These protein-bound molecules are only released when blood levels of the unattached hormone begin to decline. In this way, a week's worth of reserve hormone is maintained in the blood. Increased T<sub>3</sub> and T<sub>4</sub> levels in the blood inhibit the release of TSH, which results in lower T<sub>3</sub> and T<sub>4</sub> release from the thyroid.

The follicular cells of the thyroid require iodides (anions of iodine) in order to synthesize T<sub>3</sub> and T<sub>4</sub>. Iodides obtained from the diet are actively transported into follicle cells resulting in a concentration that is approximately 30 times higher than in blood. The typical diet in North America provides more iodine than required due to the addition of iodide to table

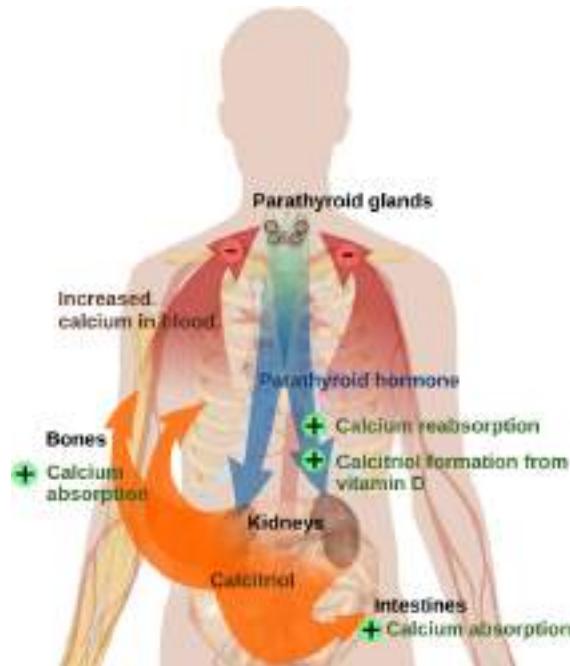

salt. Inadequate iodine intake, which occurs in many developing countries, results in an inability to synthesize T<sub>3</sub> and T<sub>4</sub> hormones. The thyroid gland enlarges in a condition called **goiter**, which is caused by overproduction of TSH without the formation of thyroid hormone. Thyroglobulin is contained in a fluid called colloid, and TSH stimulation results in higher levels of colloid accumulation in the thyroid. In the absence of iodine, this is not converted to thyroid hormone, and colloid begins to accumulate more and more in the thyroid gland, leading to goiter.

Disorders can arise from both the underproduction and overproduction of thyroid hormones. **Hypothyroidism**, underproduction of the thyroid hormones, can cause a low metabolic rate leading to weight gain, sensitivity to cold, and reduced mental activity, among other symptoms. In children, hypothyroidism can cause cretinism, which can lead to mental retardation and growth defects. **Hyperthyroidism**, the overproduction of thyroid hormones, can lead to an increased metabolic rate and its effects: weight loss, excess heat production, sweating, and an increased heart rate. Graves' disease is one example of a hyperthyroid condition.

## Hormonal Control of Blood Calcium Levels

Regulation of blood calcium concentrations is important for generation of muscle contractions and nerve impulses, which are electrically stimulated. If calcium levels get too high, membrane permeability to sodium decreases and membranes become less responsive. If calcium levels get too low, membrane permeability to sodium increases and convulsions or muscle spasms can result.

Blood calcium levels are regulated by **parathyroid hormone (PTH)**, which is produced by the parathyroid glands, as illustrated in **Figure 28.12**. PTH is released in response to low blood Ca<sup>2+</sup> levels. PTH increases Ca<sup>2+</sup> levels by targeting the skeleton, the kidneys, and the intestine. In the skeleton, PTH stimulates osteoclasts, which causes bone to be reabsorbed, releasing Ca<sup>2+</sup> from bone into the blood. PTH also inhibits osteoblasts, reducing Ca<sup>2+</sup> deposition in bone. In the intestines, PTH increases dietary Ca<sup>2+</sup> absorption, and in the kidneys, PTH stimulates reabsorption of the Ca<sup>2+</sup>. While PTH acts directly on the kidneys to increase Ca<sup>2+</sup> reabsorption, its effects on the intestine are indirect. PTH triggers the formation of calcitriol, an active form of vitamin D, which acts on the intestines to increase absorption of dietary calcium. PTH release is inhibited by rising blood calcium levels.

**Figure 28.12** Parathyroid hormone (PTH) is released in response to low blood calcium levels. It increases blood calcium levels by targeting the skeleton, the kidneys, and the intestine. (credit: modification of work by Mikael Häggström)

Hyperparathyroidism results from an overproduction of parathyroid hormone. This results in excessive calcium being removed from bones and introduced into blood circulation, producing structural weakness of the bones, which can lead to deformation and fractures, plus nervous system impairment due to high blood calcium levels. Hypoparathyroidism, the underproduction of PTH, results in extremely low levels of blood calcium, which causes impaired muscle function and may result in tetany (severe sustained muscle contraction).

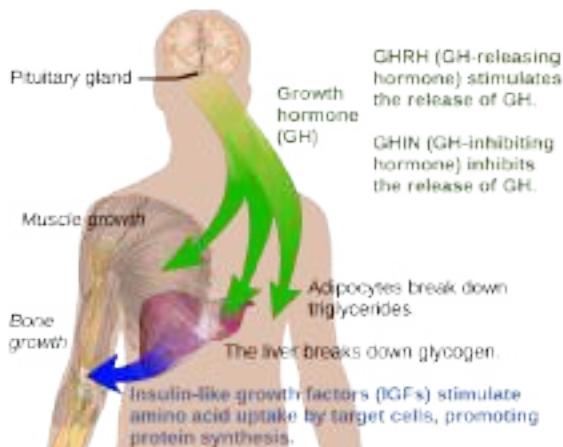

The hormone **calcitonin**, which is produced by the parafollicular or C cells of the thyroid, has the opposite effect on blood

calcium levels as does PTH. Calcitonin decreases blood calcium levels by inhibiting osteoclasts, stimulating osteoblasts, and stimulating calcium excretion by the kidneys. This results in calcium being added to the bones to promote structural integrity. Calcitonin is most important in children (when it stimulates bone growth), during pregnancy (when it reduces maternal bone loss), and during prolonged starvation (because it reduces bone mass loss). In healthy nonpregnant, unstarved adults, the role of calcitonin is unclear.

## Hormonal Regulation of Growth

Hormonal regulation is required for the growth and replication of most cells in the body. **Growth hormone (GH)**, produced by the anterior portion of the pituitary gland, accelerates the rate of protein synthesis, particularly in skeletal muscle and bones. Growth hormone has direct and indirect mechanisms of action. The first direct action of GH is stimulation of triglyceride breakdown (lipolysis) and release into the blood by adipocytes. This results in a switch by most tissues from utilizing glucose as an energy source to utilizing fatty acids. This process is called a **glucose-sparing effect**. In another direct mechanism, GH stimulates glycogen breakdown in the liver; the glycogen is then released into the blood as glucose. Blood glucose levels increase as most tissues are utilizing fatty acids instead of glucose for their energy needs. The GH mediated increase in blood glucose levels is called a **diabetogenic effect** because it is similar to the high blood glucose levels seen in diabetes mellitus.

The indirect mechanism of GH action is mediated by **insulin-like growth factors (IGFs)** or somatomedins, which are a family of growth-promoting proteins produced by the liver, which stimulates tissue growth. IGFs stimulate the uptake of amino acids from the blood, allowing the formation of new proteins, particularly in skeletal muscle cells, cartilage cells, and other target cells, as shown in **Figure 28.13**. This is especially important after a meal, when glucose and amino acid concentration levels are high in the blood. GH levels are regulated by two hormones produced by the hypothalamus. GH release is stimulated by **growth hormone-releasing hormone (GHRH)** and is inhibited by **growth hormone-inhibiting hormone (GHIH)**, also called somatostatin.

**Figure 28.13** Growth hormone directly accelerates the rate of protein synthesis in skeletal muscle and bones. Insulin-like growth factor 1 (IGF-1) is activated by growth hormone and also allows formation of new proteins in muscle cells and bone. (credit: modification of work by Mikael Häggström)

A balanced production of growth hormone is critical for proper development. Underproduction of GH in adults does not appear to cause any abnormalities, but in children it can result in **pituitary dwarfism**, in which growth is reduced. Pituitary dwarfism is characterized by symmetric body formation. In some cases, individuals are under 30 inches in height. Oversecretion of growth hormone can lead to **gigantism** in children, causing excessive growth. In some documented cases, individuals can reach heights of over eight feet. In adults, excessive GH can lead to **acromegaly**, a condition in which there is enlargement of bones in the face, hands, and feet that are still capable of growth.

## Hormonal Regulation of Stress

When a threat or danger is perceived, the body responds by releasing hormones that will ready it for the “fight-or-flight” response. The effects of this response are familiar to anyone who has been in a stressful situation: increased heart rate, dry mouth, and hair standing up.

# eVolution CONNECTION

## Fight-or-Flight Response

Interactions of the endocrine hormones have evolved to ensure the body's internal environment remains stable. Stressors are stimuli that disrupt homeostasis. The sympathetic division of the vertebrate autonomic nervous system has evolved the fight-or-flight response to counter stress-induced disruptions of homeostasis. In the initial alarm phase, the sympathetic nervous system stimulates an increase in energy levels through increased blood glucose levels. This prepares the body for physical activity that may be required to respond to stress: to either fight for survival or to flee from danger.

However, some stresses, such as illness or injury, can last for a long time. Glycogen reserves, which provide energy in the short-term response to stress, are exhausted after several hours and cannot meet long-term energy needs. If glycogen reserves were the only energy source available, neural functioning could not be maintained once the reserves became depleted due to the nervous system's high requirement for glucose. In this situation, the body has evolved a response to counter long-term stress through the actions of the glucocorticoids, which ensure that long-term energy requirements can be met. The glucocorticoids mobilize lipid and protein reserves, stimulate gluconeogenesis, conserve glucose for use by neural tissue, and stimulate the conservation of salts and water. The mechanisms to maintain homeostasis that are described here are those observed in the human body. However, the fight-or-flight response exists in some form in all vertebrates.

Explain why the fight-or-flight response is advantageous in the short-term but not in the long-term.

- a. Fight-or-flight reduces access to glucose reserves and these get depleted fairly quickly.
- b. Fight-or-flight reduces access to glycogen reserves and these get depleted fairly quickly.
- c. Fight-or-flight stimulates access to glucose reserves, but these get depleted fairly quickly.
- d. Fight-or-flight stimulates access to glycogen reserves, but these get depleted fairly quickly.

The sympathetic nervous system regulates the stress response via the hypothalamus. Stressful stimuli cause the hypothalamus to signal the adrenal medulla (which mediates short-term stress responses) via nerve impulses, and the adrenal cortex, which mediates long-term stress responses, via the hormone **adrenocorticotrophic hormone (ACTH)**, which is produced by the anterior pituitary.

### Short-term Stress Response

When presented with a stressful situation, the body responds by calling for the release of hormones that provide a burst of energy. The hormones **epinephrine** (also known as adrenaline) and **norepinephrine** (also known as noradrenaline) are released by the adrenal medulla. How do these hormones provide a burst of energy? Epinephrine and norepinephrine increase blood glucose levels by stimulating the liver and skeletal muscles to break down glycogen and by stimulating glucose release by liver cells. Additionally, these hormones increase oxygen availability to cells by increasing the heart rate and dilating the bronchioles. The hormones also prioritize body function by increasing blood supply to essential organs such as the heart, brain, and skeletal muscles, while restricting blood flow to organs not in immediate need, such as the skin, digestive system, and kidneys. Epinephrine and norepinephrine are collectively called catecholamines.

Watch this **Discovery Channel animation** (<http://openstaxcollege.org/l/adrenaline>) describing the flight-or-flight response.

When would you receive a burst of energy as your body undergoes a fight-or-flight response.

- a. increase in blood calcium levels
- b. release of carbon monoxide in the atmosphere
- c. any threat or life-or-death scenario
- d. physical exercise such as running and swimming

### **Long-term Stress Response**

Long-term stress response differs from short-term stress response. The body cannot sustain the bursts of energy mediated by epinephrine and norepinephrine for long times. Instead, other hormones come into play. In a long-term stress response, the hypothalamus triggers the release of ACTH from the anterior pituitary gland. The adrenal cortex is stimulated by ACTH to release steroid hormones called **corticosteroids**. Corticosteroids turn on transcription of certain genes in the nuclei of target cells. They change enzyme concentrations in the cytoplasm and affect cellular metabolism. There are two main corticosteroids: glucocorticoids such as **cortisol**, and mineralocorticoids such as aldosterone. These hormones target the breakdown of fat into fatty acids in the adipose tissue. The fatty acids are released into the bloodstream for other tissues to use for ATP production. The **glucocorticoids** primarily affect glucose metabolism by stimulating glucose synthesis. Glucocorticoids also have anti-inflammatory properties through inhibition of the immune system. For example, cortisone is used as an anti-inflammatory medication; however, it cannot be used long term as it increases susceptibility to disease due to its immune-suppressing effects.

Mineralocorticoids function to regulate ion and water balance of the body. The hormone aldosterone stimulates the reabsorption of water and sodium ions in the kidney, which results in increased blood pressure and volume.

Hypersecretion of glucocorticoids can cause a condition known as **Cushing's disease**, characterized by a shifting of fat storage areas of the body. This can cause the accumulation of adipose tissue in the face and neck, and excessive glucose in the blood. Hyposecretion of the corticosteroids can cause **Addison's disease**, which may result in bronzing of the skin, hypoglycemia, and low electrolyte levels in the blood.

## science practices CONNECTION for AP<sup>®</sup> Courses

### **Activity**

Selecting a hormone of your choice, create a visual representation (e.g., diagram) to describe the effect(s) of the hormone on a body system, for example, reproductive system, or process, for example, maintaining normal blood glucose levels.

## 28.4 | Regulation of Hormone Production

In this section, you will explore the following questions:

- How is hormone production regulated?
- What are examples of different stimuli that control hormone levels in the body?

### Connection for AP® Courses

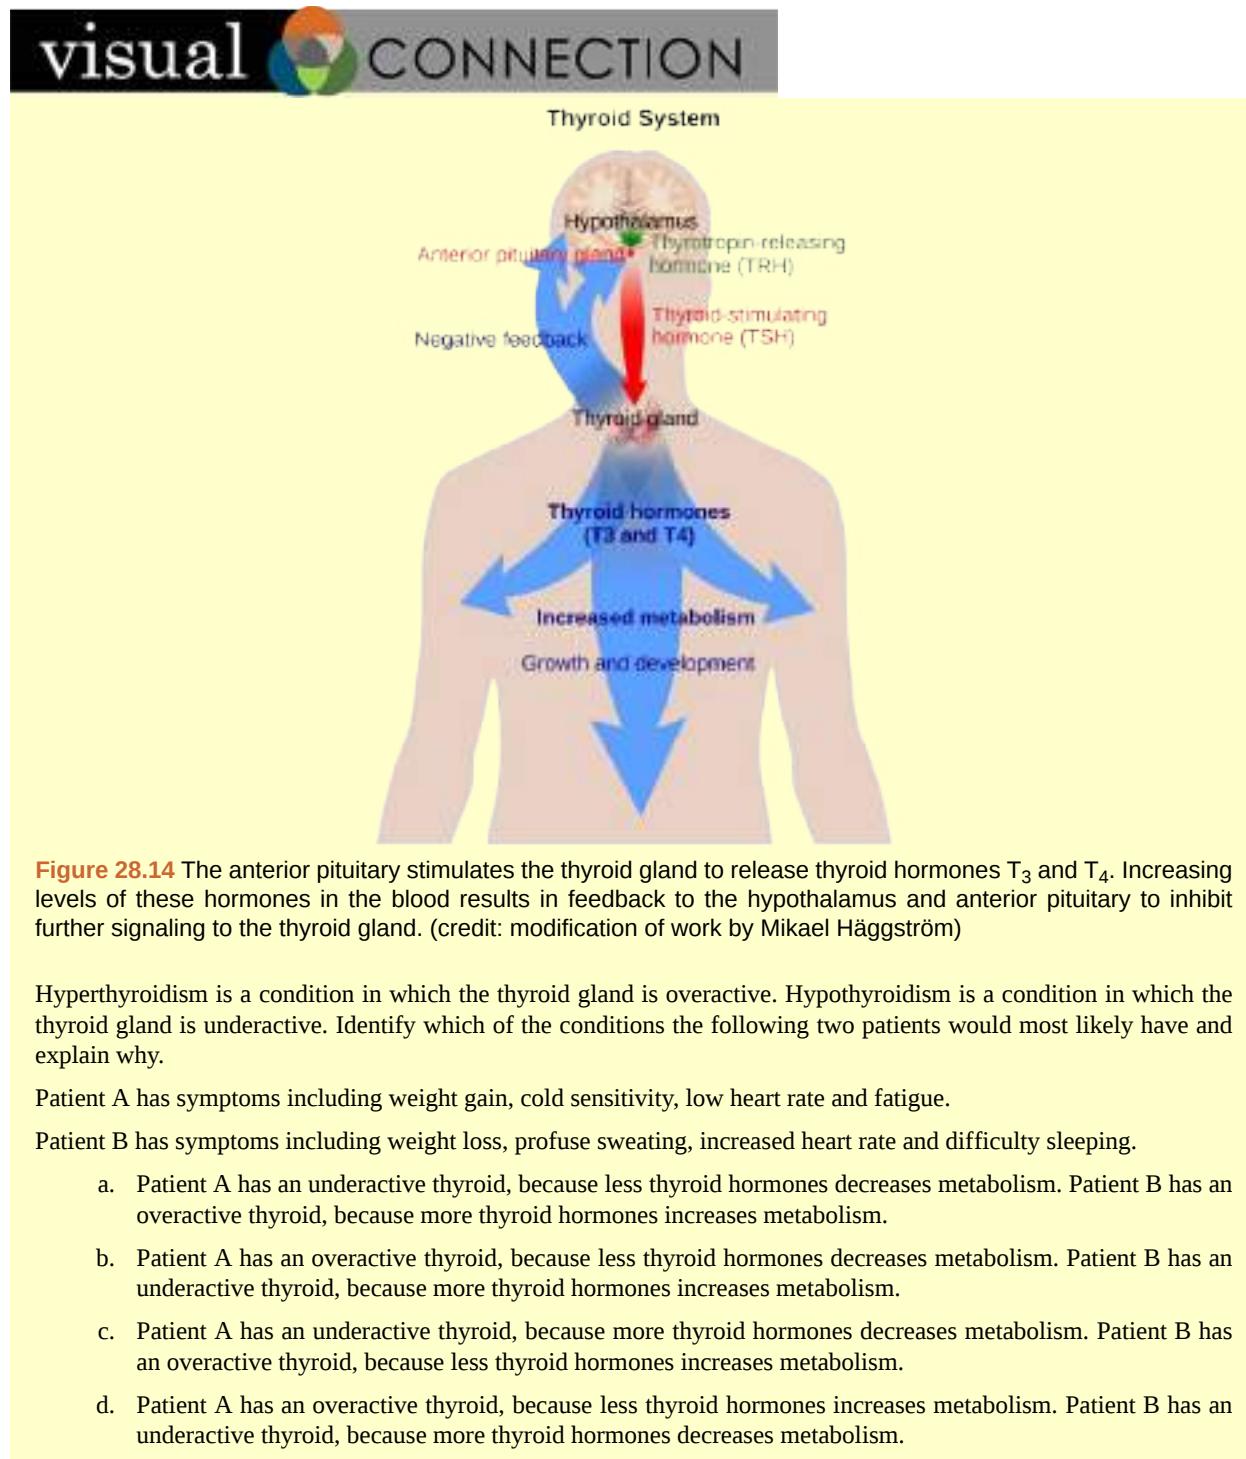

Hormone production and release are often controlled by **negative feedback** or **positive feedback**, although regulation by negative feedback is more common. In negative feedback, a stimulus elicits the release of a hormone that produces a response, and once the response reaches a certain level, it sends a signal that stops additional release of the hormone. In this way, the concentration of hormones in blood is maintained within a narrow range. For example, the anterior pituitary stimulates the thyroid gland to release thyroid hormones T<sub>3</sub> and T<sub>4</sub>. Increased levels of these hormones result in feedback to the hypothalamus and anterior pituitary to inhibit further signaling to the thyroid gland.

Some hormones are regulated by positive feedback in which the response is amplified; an example of hormone regulation by positive feedback is the production of oxytocin during labor and childbirth as uterine contractions cause the production and release of more oxytocin. Disruptions in the mechanisms of feedback often result in deleterious consequences, such as diabetes mellitus resulting in decreased insulin production.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Hormone production and release are primarily controlled by negative feedback. In negative feedback systems, a stimulus elicits the release of a substance; once the substance reaches a certain level, it sends a signal that stops further release of the substance. In this way, the concentration of hormones in blood is maintained within a narrow range. For example, the anterior pituitary signals the thyroid to release thyroid hormones. Increasing levels of these hormones in the blood then give feedback to the hypothalamus and anterior pituitary to inhibit further signaling to the thyroid gland, as illustrated in **Figure 28.14**. There are three mechanisms by which endocrine glands are stimulated to synthesize and release hormones: humoral stimuli, hormonal stimuli, and neural stimuli.

## Humoral Stimuli

The term “humoral” is derived from the term “humor,” which refers to bodily fluids such as blood. A **humoral stimulus** refers to the control of hormone release in response to changes in extracellular fluids such as blood or the ion concentration in the blood. For example, a rise in blood glucose levels triggers the pancreatic release of insulin. Insulin causes blood glucose levels to drop, which signals the pancreas to stop producing insulin in a negative feedback loop.

## Hormonal Stimuli

**Hormonal stimuli** refers to the release of a hormone in response to another hormone. A number of endocrine glands release hormones when stimulated by hormones released by other endocrine glands. For example, the hypothalamus produces hormones that stimulate the anterior portion of the pituitary gland. The anterior pituitary in turn releases hormones that regulate hormone production by other endocrine glands. The anterior pituitary releases the thyroid-stimulating hormone, which then stimulates the thyroid gland to produce the hormones  $T_3$  and  $T_4$ . As blood concentrations of  $T_3$  and  $T_4$  rise, they inhibit both the pituitary and the hypothalamus in a negative feedback loop.

## Neural Stimuli

In some cases, the nervous system directly stimulates endocrine glands to release hormones, which is referred to as **neural stimuli**. Recall that in a short-term stress response, the hormones epinephrine and norepinephrine are important for providing the bursts of energy required for the body to respond. Here, neuronal signaling from the sympathetic nervous system directly stimulates the adrenal medulla to release the hormones epinephrine and norepinephrine in response to stress.

### Activity

Create a visual representation to describe the regulation of blood sugar levels, growth spurts in teenagers, and events associated with labor and childbirth. Then explain how disruptions to these regulatory processes (e.g., failure to produce insulin) can affect homeostasis in the body.

## 28.5 | Endocrine Glands

In this section, you will explore the following questions:

- What are the roles of different glands in the endocrine system?
- How do different glands work together to maintain homeostasis?

### Connection for AP® Courses

The specific information in this section is outside the scope for AP®. You do not have to memorize a list of endocrine glands, their locations in the body, and the hormones they produce. However, you might want to focus on one or two examples and consider how endocrine glands and their hormone products work together and with the nervous system to communicate and regulate the body's physiology to maintain homeostasis. For example, the hypothalamus in vertebrates integrates the endocrine and nervous systems. The hypothalamus is located in the brain and receives input from the body and other brain areas and initiates endocrine responses to environmental changes. The pituitary gland is attached to the hypothalamus and receives products from the hypothalamus, causing, in turn, the secretion of anterior and posterior pituitary hormones such as growth hormone (GH), follicle-stimulating hormone (FSH), luteinizing hormone (LH), and oxytocin. The thyroid gland, located in the neck just below the larynx, releases  $T_3$  and  $T_4$  in response to thyroid stimulating hormone (TSH) produced by the anterior pituitary. Another example is how frog development is disrupted by estrogen in waste water, which you can read more about at the [Science News website \(<http://openstaxcollege.org/l/32frog>\)](http://openstaxcollege.org/l/32frog).

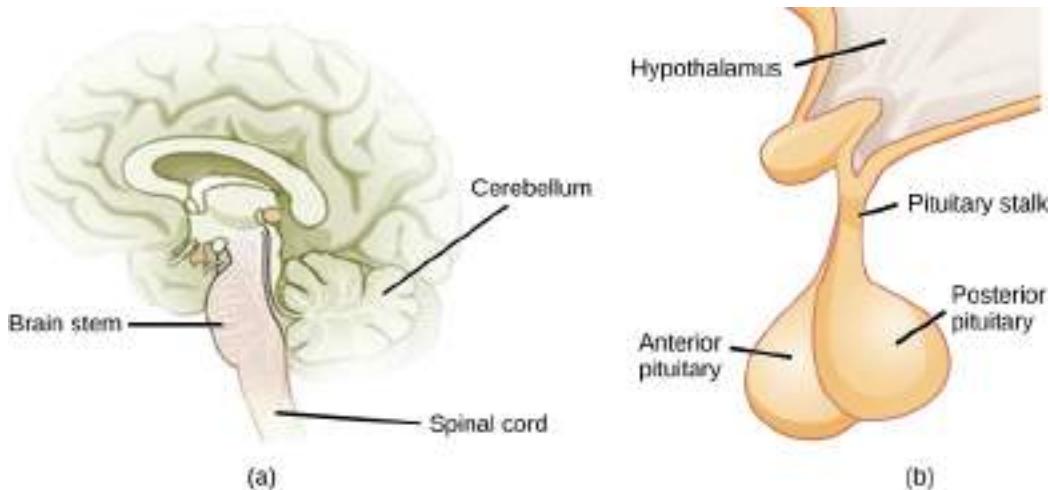

Both the endocrine and nervous systems use chemical signals to communicate and regulate the body's physiology. The endocrine system releases hormones that act on target cells to regulate development, growth, energy metabolism, reproduction, and many behaviors. The nervous system releases neurotransmitters or neurohormones that regulate neurons, muscle cells, and endocrine cells. Because the neurons can regulate the release of hormones, the nervous and endocrine systems work in a coordinated manner to regulate the body's physiology.

### Hypothalamic-Pituitary Axis

The **hypothalamus** in vertebrates integrates the endocrine and nervous systems. The hypothalamus is an endocrine organ

located in the diencephalon of the brain. It receives input from the body and other brain areas and initiates endocrine responses to environmental changes. The hypothalamus acts as an endocrine organ, synthesizing hormones and transporting them along axons to the posterior pituitary gland. It synthesizes and secretes regulatory hormones that control the endocrine cells in the anterior pituitary gland. The hypothalamus contains autonomic centers that control endocrine cells in the adrenal medulla via neuronal control.

The **pituitary gland**, sometimes called the hypophysis or “master gland” is located at the base of the brain in the sella turcica, a groove of the sphenoid bone of the skull, illustrated in **Figure 28.15**. It is attached to the hypothalamus via a stalk called the **pituitary stalk** (or infundibulum). The anterior portion of the pituitary gland is regulated by releasing or release-inhibiting hormones produced by the hypothalamus, and the posterior pituitary receives signals via neurosecretory cells to release hormones produced by the hypothalamus. The pituitary has two distinct regions—the anterior pituitary and the posterior pituitary—which between them secrete nine different peptide or protein hormones. The posterior lobe of the pituitary gland contains axons of the hypothalamic neurons.

**Figure 28.15** The pituitary gland is located at (a) the base of the brain and (b) connected to the hypothalamus by the pituitary stalk. (credit a: modification of work by NCI; credit b: modification of work by Gray's Anatomy)

### Anterior Pituitary

The **anterior pituitary** gland, or adenohypophysis, is surrounded by a capillary network that extends from the hypothalamus, down along the infundibulum, and to the anterior pituitary. This capillary network is a part of the **hypophyseal portal system** that carries substances from the hypothalamus to the anterior pituitary and hormones from the anterior pituitary into the circulatory system. A portal system carries blood from one capillary network to another; therefore, the hypophyseal portal system allows hormones produced by the hypothalamus to be carried directly to the anterior pituitary without first entering the circulatory system.

The anterior pituitary produces seven hormones: growth hormone (GH), prolactin (PRL), thyroid-stimulating hormone (TSH), melanin-stimulating hormone (MSH), adrenocorticotropic hormone (ACTH), follicle-stimulating hormone (FSH), and luteinizing hormone (LH). Anterior pituitary hormones are sometimes referred to as tropic hormones, because they control the functioning of other organs. While these hormones are produced by the anterior pituitary, their production is controlled by regulatory hormones produced by the hypothalamus. These regulatory hormones can be releasing hormones or inhibiting hormones, causing more or less of the anterior pituitary hormones to be secreted. These travel from the hypothalamus through the hypophyseal portal system to the anterior pituitary where they exert their effect. Negative feedback then regulates how much of these regulatory hormones are released and how much anterior pituitary hormone is secreted.

### Posterior Pituitary

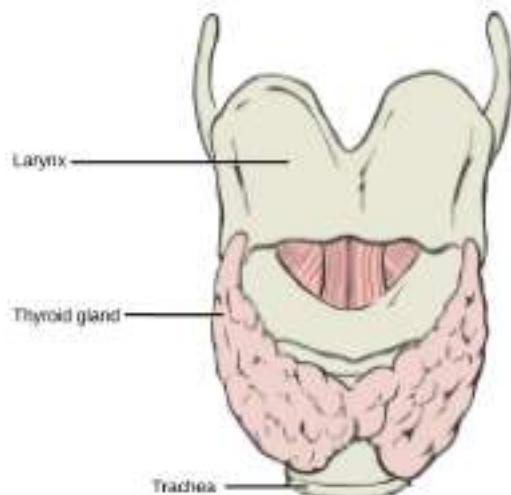

The **posterior pituitary** is significantly different in structure from the anterior pituitary. It is a part of the brain, extending down from the hypothalamus, and contains mostly nerve fibers and neuroglial cells, which support axons that extend from the hypothalamus to the posterior pituitary. The posterior pituitary and the infundibulum together are referred to as the neurohypophysis.

The hormones antidiuretic hormone (ADH), also known as vasopressin, and oxytocin are produced by neurons in the hypothalamus and transported within these axons along the infundibulum to the posterior pituitary. They are released into the circulatory system via neural signaling from the hypothalamus. These hormones are considered to be posterior pituitary hormones, even though they are produced by the hypothalamus, because that is where they are released into the

circulatory system. The posterior pituitary itself does not produce hormones, but instead stores hormones produced by the hypothalamus and releases them into the blood stream.

## Thyroid Gland

The **thyroid gland** is located in the neck, just below the larynx and in front of the trachea, as shown in [Figure 28.16](#). It is a butterfly-shaped gland with two lobes that are connected by the **isthmus**. It has a dark red color due to its extensive vascular system. When the thyroid swells due to dysfunction, it can be felt under the skin of the neck.

[Figure 28.16](#) This illustration shows the location of the thyroid gland.

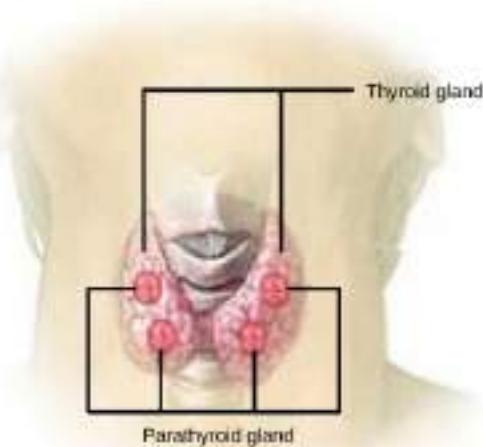

The thyroid gland is made up of many spherical thyroid follicles, which are lined with a simple cuboidal epithelium. These follicles contain a viscous fluid, called **colloid**, which stores the glycoprotein thyroglobulin, the precursor to the thyroid hormones. The follicles produce hormones that can be stored in the colloid or released into the surrounding capillary network for transport to the rest of the body via the circulatory system.

Thyroid follicle cells synthesize the hormone thyroxine, which is also known as  $T_4$  because it contains four atoms of iodine, and triiodothyronine, also known as  $T_3$  because it contains three atoms of iodine. Follicle cells are stimulated to release stored  $T_3$  and  $T_4$  by thyroid stimulating hormone (TSH), which is produced by the anterior pituitary. These thyroid hormones increase the rates of mitochondrial ATP production.

A third hormone, calcitonin, is produced by **parafollicular cells** of the thyroid either releasing hormones or inhibiting hormones. Calcitonin release is not controlled by TSH, but instead is released when calcium ion concentrations in the blood rise. Calcitonin functions to help regulate calcium concentrations in body fluids. It acts in the bones to inhibit osteoclast activity and in the kidneys to stimulate excretion of calcium. The combination of these two events lowers body fluid levels of calcium.

## Parathyroid Glands

Most people have four **parathyroid glands**; however, the number can vary from two to six. These glands are located on the posterior surface of the thyroid gland, as shown in [Figure 28.17](#). Normally, there is a superior gland and an inferior gland associated with each of the thyroid's two lobes. Each parathyroid gland is covered by connective tissue and contains many secretory cells that are associated with a capillary network.

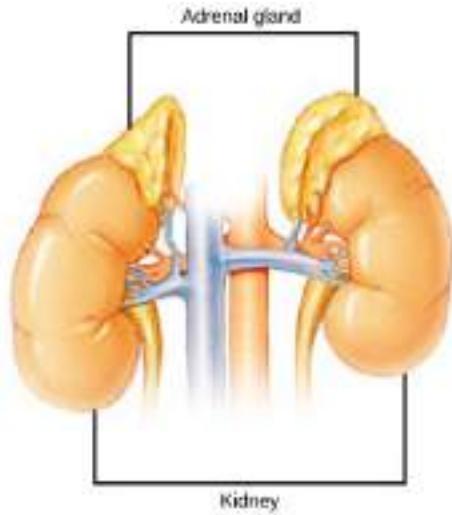

**Figure 28.17** The parathyroid glands are located on the posterior of the thyroid gland. (credit: modification of work by NCI)

The parathyroid glands produce parathyroid hormone (PTH). PTH increases blood calcium concentrations when calcium ion levels fall below normal. PTH (1) enhances reabsorption of  $\text{Ca}^{2+}$  by the kidneys, (2) stimulates osteoclast activity and inhibits osteoblast activity, and (3) it stimulates synthesis and secretion of calcitriol by the kidneys, which enhances  $\text{Ca}^{2+}$  absorption by the digestive system. PTH is produced by chief cells of the parathyroid. PTH and calcitonin work in opposition to one another to maintain homeostatic  $\text{Ca}^{2+}$  levels in body fluids. Another type of cells, oxyphil cells, exist in the parathyroid but their function is not known. These hormones encourage bone growth, muscle mass, and blood cell formation in children and women.

## Adrenal Glands

The **adrenal glands** are associated with the kidneys; one gland is located on top of each kidney as illustrated in **Figure 28.18**. The adrenal glands consist of an outer adrenal cortex and an inner adrenal medulla. These regions secrete different hormones.

**Figure 28.18** The location of the adrenal glands on top of the kidneys is shown. (credit: modification of work by NCI)

### Adrenal Cortex

The **adrenal cortex** is made up of layers of epithelial cells and associated capillary networks. These layers form three distinct regions: an outer zona glomerulosa that produces mineralocorticoids, a middle zona fasciculata that produces glucocorticoids, and an inner zona reticularis that produces androgens.

The main mineralocorticoid is aldosterone, which regulates the concentration of  $\text{Na}^+$  ions in urine, sweat, pancreas, and saliva. Aldosterone release from the adrenal cortex is stimulated by a decrease in blood concentrations of sodium ions,

blood volume, or blood pressure, or by an increase in blood potassium levels.

The three main glucocorticoids are cortisol, corticosterone, and cortisone. The glucocorticoids stimulate the synthesis of glucose and gluconeogenesis (converting a non-carbohydrate to glucose) by liver cells and they promote the release of fatty acids from adipose tissue. These hormones increase blood glucose levels to maintain levels within a normal range between meals. These hormones are secreted in response to ACTH and levels are regulated by negative feedback.

Androgens are sex hormones that promote masculinity. They are produced in small amounts by the adrenal cortex in both males and females. They do not affect sexual characteristics and may supplement sex hormones released from the gonads.

### **Adrenal Medulla**

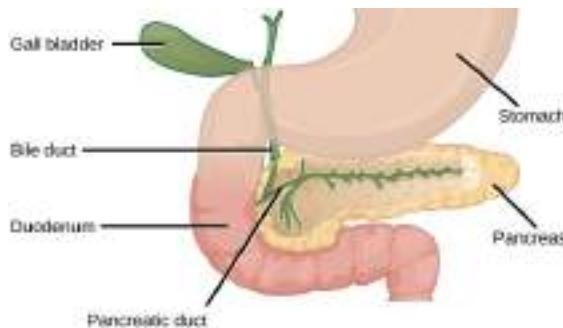

The **adrenal medulla** contains large, irregularly shaped cells that are closely associated with blood vessels. These cells are innervated by preganglionic autonomic nerve fibers from the central nervous system.

The adrenal medulla contains two types of secretory cells: one that produces epinephrine (adrenaline) and another that produces norepinephrine (noradrenaline). Epinephrine is the primary adrenal medulla hormone accounting for 75 to 80 percent of its secretions. Epinephrine and norepinephrine increase heart rate, breathing rate, cardiac muscle contractions, blood pressure, and blood glucose levels. They also accelerate the breakdown of glucose in skeletal muscles and stored fats in adipose tissue.

The release of epinephrine and norepinephrine is stimulated by neural impulses from the sympathetic nervous system. Secretion of these hormones is stimulated by acetylcholine release from preganglionic sympathetic fibers innervating the adrenal medulla. These neural impulses originate from the hypothalamus in response to stress to prepare the body for the fight-or-flight response.

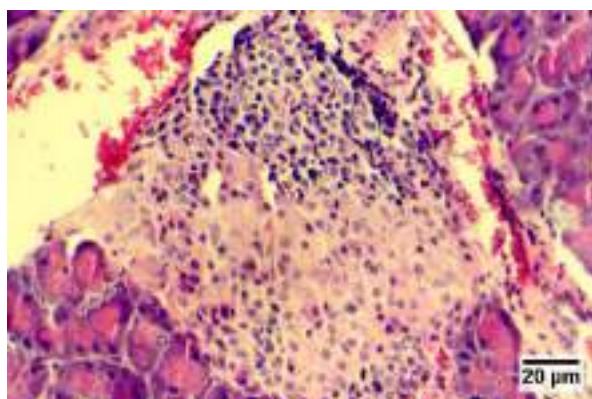

## **Pancreas**

The **pancreas**, illustrated in **Figure 28.19**, is an elongated organ that is located between the stomach and the proximal portion of the small intestine. It contains both exocrine cells that excrete digestive enzymes and endocrine cells that release hormones. It is sometimes referred to as a heterocrine gland because it has both endocrine and exocrine functions.

**Figure 28.19** The pancreas is found underneath the stomach and points toward the spleen. (credit: modification of work by NCI)

The endocrine cells of the pancreas form clusters called pancreatic islets or the **islets of Langerhans**, as visible in the micrograph shown in **Figure 28.20**. The pancreatic islets contain two primary cell types: **alpha cells**, which produce the hormone glucagon, and **beta cells**, which produce the hormone insulin. These hormones regulate blood glucose levels. As blood glucose levels decline, alpha cells release glucagon to raise the blood glucose levels by increasing rates of glycogen breakdown and glucose release by the liver. When blood glucose levels rise, such as after a meal, beta cells release insulin to lower blood glucose levels by increasing the rate of glucose uptake in most body cells, and by increasing glycogen synthesis in skeletal muscles and the liver. Together, glucagon and insulin regulate blood glucose levels.

**Figure 28.20** The islets of Langerhans are clusters of endocrine cells found in the pancreas; they stain lighter than surrounding cells. (credit: modification of work by Muhammad T. Tabiin, Christopher P. White, Grant Morahan, and Bernard E. Tuch; scale-bar data from Matt Russell)

## Pineal Gland

The pineal gland produces melatonin. The rate of melatonin production is affected by the photoperiod. Collaterals from the visual pathways innervate the pineal gland. During the day photoperiod, little melatonin is produced; however, melatonin production increases during the dark photoperiod (night). In some mammals, melatonin has an inhibitory affect on reproductive functions by decreasing production and maturation of sperm, oocytes, and reproductive organs. Melatonin is an effective antioxidant, protecting the CNS from free radicals such as nitric oxide and hydrogen peroxide. Lastly, melatonin is involved in biological rhythms, particularly circadian rhythms such as the sleep-wake cycle and eating habits.

## Gonads

The gonads—the male testes and female ovaries—produce steroid hormones. The testes produce androgens, testosterone being the most prominent, which allow for the development of secondary sex characteristics and the production of sperm cells. The ovaries produce estradiol and progesterone, which cause secondary sex characteristics and prepare the body for childbirth.

### Endocrine Glands and their Associated Hormones

| Endocrine Gland      | Associated Hormones                | Effect                                                                                                                      |
|----------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Hypothalamus         | releasing and inhibiting hormones  | regulate hormone release from pituitary gland; produce oxytocin; produce uterine contractions and milk secretion in females |
|                      | antidiuretic hormone (ADH)         | water reabsorption from kidneys; vasoconstriction to increase blood pressure                                                |
| Pituitary (Anterior) | growth hormone (GH)                | promotes growth of body tissues, protein synthesis; metabolic functions                                                     |
|                      | prolactin (PRL)                    | promotes milk production                                                                                                    |
|                      | thyroid stimulating hormone (TSH)  | stimulates thyroid hormone release                                                                                          |
|                      | adrenocorticotropic hormone (ACTH) | stimulates hormone release by adrenal cortex, glucocorticoids                                                               |
|                      | follicle-stimulating hormone (FSH) | stimulates gamete production (both ova and sperm); secretion of estradiol                                                   |
|                      | luteinizing hormone (LH)           | stimulates androgen production by gonads; ovulation, secretion of progesterone                                              |

**Table 28.1**

## Endocrine Glands and their Associated Hormones

| Endocrine Gland       | Associated Hormones                  | Effect                                                                                                                                      |
|-----------------------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|                       | melanocyte-stimulating hormone (MSH) | stimulates melanocytes of the skin increasing melanin pigment production.                                                                   |
| Pituitary (Posterior) | antidiuretic hormone (ADH)           | stimulates water reabsorption by kidneys                                                                                                    |
|                       | oxytocin                             | stimulates uterine contractions during childbirth; milk ejection; stimulates ductus deferens and prostate gland contraction during emission |
| Thyroid               | thyroxine, triiodothyronine          | stimulate and maintain metabolism; growth and development                                                                                   |
|                       | calcitonin                           | reduces blood $\text{Ca}^{2+}$ levels                                                                                                       |
| Parathyroid           | parathyroid hormone (PTH)            | increases blood $\text{Ca}^{2+}$ levels                                                                                                     |
| Adrenal (Cortex)      | aldosterone                          | increases blood $\text{Na}^+$ levels; increase $\text{K}^+$ secretion                                                                       |
|                       | cortisol, corticosterone, cortisone  | increase blood glucose levels; anti-inflammatory effects                                                                                    |
| Adrenal (Medulla)     | epinephrine, norepinephrine          | stimulate fight-or-flight response; increase blood glucose levels; increase metabolic activities                                            |
| Pancreas              | insulin                              | reduces blood glucose levels                                                                                                                |
|                       | glucagon                             | increases blood glucose levels                                                                                                              |
| Pineal gland          | melatonin                            | regulates some biological rhythms and protects CNS from free radicals                                                                       |
| Testes                | androgens                            | regulate, promote, increase or maintain sperm production; male secondary sexual characteristics                                             |
| Ovaries               | estrogen                             | promotes uterine lining growth; female secondary sexual characteristics                                                                     |
|                       | progesterins                         | promote and maintain uterine lining growth                                                                                                  |

**Table 28.1**

## Organs with Secondary Endocrine Functions

There are several organs whose primary functions are non-endocrine but that also possess endocrine functions. These include the heart, kidneys, intestines, thymus, gonads, and adipose tissue.

The heart possesses endocrine cells in the walls of the atria that are specialized cardiac muscle cells. These cells release the hormone **atrial natriuretic peptide (ANP)** in response to increased blood volume. High blood volume causes the cells to be stretched, resulting in hormone release. ANP acts on the kidneys to reduce the reabsorption of  $\text{Na}^+$ , causing  $\text{Na}^+$  and water to be excreted in the urine. ANP also reduces the amounts of renin released by the kidneys and aldosterone released by the adrenal cortex, further preventing the retention of water. In this way, ANP causes a reduction in blood volume and blood pressure, and reduces the concentration of  $\text{Na}^+$  in the blood.

The gastrointestinal tract produces several hormones that aid in digestion. The endocrine cells are located in the mucosa of the GI tract throughout the stomach and small intestine. Some of the hormones produced include gastrin, secretin, and cholecystokinin, which are secreted in the presence of food, and some of which act on other organs such as the pancreas, gallbladder, and liver. They trigger the release of gastric juices, which help to break down and digest food in the GI tract.

While the adrenal glands associated with the kidneys are major **endocrine glands**, the kidneys themselves also possess endocrine function. Renin is released in response to decreased blood volume or pressure and is part of the renin-angiotensin-

aldosterone system that leads to the release of aldosterone. Aldosterone then causes the retention of  $\text{Na}^+$  and water, raising blood volume. The kidneys also release calcitriol, which aids in the absorption of  $\text{Ca}^{2+}$  and phosphate ions. **Erythropoietin (EPO)** is a protein hormone that triggers the formation of red blood cells in the bone marrow. EPO is released in response to low oxygen levels. Because red blood cells are oxygen carriers, increased production results in greater oxygen delivery throughout the body. EPO has been used by athletes to improve performance, as greater oxygen delivery to muscle cells allows for greater endurance. Because red blood cells increase the viscosity of blood, artificially high levels of EPO can cause severe health risks.

The **thymus** is found behind the sternum; it is most prominent in infants, becoming smaller in size through adulthood. The thymus produces hormones referred to as thymosins, which contribute to the development of the immune response.

Adipose tissue is a connective tissue found throughout the body. It produces the hormone **leptin** in response to food intake. Leptin increases the activity of anorexigenic neurons and decreases that of orexigenic neurons, producing a feeling of satiety after eating, thus affecting appetite and reducing the urge for further eating. Leptin is also associated with reproduction. It must be present for GnRH and gonadotropin synthesis to occur. Extremely thin females may enter puberty late; however, if adipose levels increase, more leptin will be produced, improving fertility.

## KEY TERMS

**acromegaly** condition caused by overproduction of GH in adults

**Addison's disease** disorder caused by the hyposecretion of corticosteroids

**adenylate cyclase** an enzyme that catalyzes the conversion of ATP to cyclic AMP

**adrenal cortex** outer portion of adrenal glands that produces corticosteroids

**adrenal gland** endocrine glands associated with the kidneys

**adrenal medulla** inner portion of adrenal glands that produces epinephrine and norepinephrine

**adrenocorticotropic hormone (ACTH)** hormone released by the anterior pituitary, which stimulates the adrenal cortex to release corticosteroids during the long-term stress response

**aldosterone** steroid hormone produced by the adrenal cortex that stimulates the reabsorption of  $\text{Na}^+$  from extracellular fluids and secretion of  $\text{K}^+$ .

**alpha cell** endocrine cell of the pancreatic islets that produces the hormone glucagon

**amino acid-derived hormone** hormone derived from amino acids

**androgen** male sex hormone such as testosterone

**anterior pituitary** portion of the pituitary gland that produces six hormones; also called adenohypophysis

**antidiuretic hormone (ADH)** hormone produced by the hypothalamus and released by the posterior pituitary that increases water reabsorption by the kidneys

**atrial natriuretic peptide (ANP)** hormone produced by the heart to reduce blood volume, pressure, and  $\text{Na}^+$  concentration

**beta cell** endocrine cell of the pancreatic islets that produces the hormone insulin

**calcitonin** hormone produced by the parafollicular cells of the thyroid gland that functions to lower blood  $\text{Ca}^{2+}$  levels and promote bone growth

**colloid** fluid inside the thyroid gland that contains the glycoprotein thyroglobulin

**corticosteroid** hormone released by the adrenal cortex in response to long-term stress

**cortisol** glucocorticoid produced in response to stress

**Cushing's disease** disorder caused by the hypersecretion of glucocorticoids

**diabetes insipidus** disorder caused by underproduction of ADH

**diabetes mellitus** disorder caused by low levels of insulin activity

**diabetogenic effect** effect of GH that causes blood glucose levels to rise similar to diabetes mellitus

**down-regulation** a decrease in the number of hormone receptors in response to increased hormone levels

**endocrine gland** gland that secretes hormones into the surrounding interstitial fluid, which then diffuse into blood and are carried to various organs and tissues within the body

**epinephrine** hormone released by the adrenal medulla in response to a short term stress

**erythropoietin (EPO)** hormone produced by the kidneys to stimulate red blood cell production in the bone marrow

**estrogens** - a group of steroid hormones, including estradiol and several others, that are produced by the ovaries and elicit

- secondary sex characteristics in females as well as control the maturation of the ova
- first messenger** the hormone that binds to a plasma membrane hormone receptor to trigger a signal transduction pathway
- follicle-stimulating hormone (FSH)** hormone produced by the anterior pituitary that stimulates gamete production
- G-protein** a membrane protein activated by the hormone first messenger to activate formation of cyclic AMP
- gigantism** condition caused by overproduction of GH in children
- glucagon** hormone produced by the alpha cells of the pancreas in response to low blood sugar; functions to raise blood sugar levels
- glucocorticoid** corticosteroid that affects glucose metabolism
- gluconeogenesis** synthesis of glucose from amino acids
- glucose-sparing effect** effect of GH that causes tissues to use fatty acids instead of glucose as an energy source
- glycogenolysis** breakdown of glycogen into glucose
- goiter** enlargement of the thyroid gland caused by insufficient dietary iodine levels
- gonadotropin** hormone that regulates the gonads, including FSH and LH
- growth hormone (GH)** hormone produced by the anterior pituitary that promotes protein synthesis and body growth
- growth hormone-inhibiting hormone (GHIH)** hormone produced by the hypothalamus that inhibits growth hormone production, also called somatostatin
- growth hormone-releasing hormone (GHRH)** hormone released by the hypothalamus that triggers the release of GH
- hormonal stimuli** release of a hormone in response to another hormone
- hormone receptor** the cellular protein that binds to a hormone
- humoral stimuli** control of hormone release in response to changes in extracellular fluids such as blood or the ion concentration in the blood
- hyperglycemia** high blood sugar level
- hyperthyroidism** overactivity of the thyroid gland
- hypoglycemia** low blood sugar level
- hypophyseal portal system** system of blood vessels that carries hormones from the hypothalamus to the anterior pituitary
- hypothyroidism** underactivity of the thyroid gland
- insulin** hormone produced by the beta cells of the pancreas in response to high blood glucose levels; functions to lower blood glucose levels
- insulin-like growth factor (IGF)** growth-promoting protein produced by the liver
- intracellular hormone receptor** a hormone receptor in the cytoplasm or nucleus of a cell
- islets of Langerhans (pancreatic islets)** endocrine cells of the pancreas
- isthmus** tissue mass that connects the two lobes of the thyroid gland
- leptin** hormone produced by adipose tissue that promotes feelings of satiety and reduces hunger
- lipid-derived hormone** hormone derived mostly from cholesterol

**mineralocorticoid** corticosteroid that affects ion and water balance

**neural stimuli** stimulation of endocrine glands by the nervous system

**norepinephrine** hormone released by the adrenal medulla in response to a short-term stress hormone production by the gonads

**osmoreceptor** receptor in the hypothalamus that monitors the concentration of electrolytes in the blood

**oxytocin** hormone released by the posterior pituitary to stimulate uterine contractions during childbirth and milk let-down in the mammary glands

**pancreas** organ located between the stomach and the small intestine that contains exocrine and endocrine cells

**parafollicular cell** thyroid cell that produces the hormone calcitonin

**parathyroid gland** gland located on the surface of the thyroid that produces parathyroid hormone

**parathyroid hormone (PTH)** hormone produced by the parathyroid glands in response to low blood  $\text{Ca}^{2+}$  levels; functions to raise blood  $\text{Ca}^{2+}$  levels

**peptide hormone** hormone composed of a polypeptide chain

**phosphodiesterase (PDE)** enzyme that deactivates cAMP, stopping hormone activity

**pituitary dwarfism** condition caused by underproduction of GH in children

**pituitary gland** endocrine gland located at the base of the brain composed of an anterior and posterior region; also called hypophysis

**pituitary stalk** (also, infundibulum) stalk that connects the pituitary gland to the hypothalamus

**plasma membrane hormone receptor** a hormone receptor on the surface of the plasma membrane of a cell

**posterior pituitary** extension of the brain that releases hormones produced by the hypothalamus; along with the infundibulum, it is also referred to as the neurohypophysis

**prolactin (PRL)** hormone produced by the anterior pituitary that stimulates milk production

**prolactin-inhibiting hormone** hormone produced by the hypothalamus that inhibits the release of prolactin

**prolactin-releasing hormone** hormone produced by the hypothalamus that stimulates the release of prolactin

**renin** enzyme produced by the juxtaglomerular apparatus of the kidneys that reacts with angiotensinogen to cause the release of aldosterone

**thymus** gland located behind the sternum that produces thymosin hormones that contribute to the development of the immune system

**thyroglobulin** glycoprotein found in the thyroid that is converted into thyroid hormone

**thyroid gland** endocrine gland located in the neck that produces thyroid hormones thyroxine and triiodothyronine

**thyroid-stimulating hormone (TSH)** hormone produced by the anterior pituitary that controls the release of  $T_3$  and  $T_4$  from the thyroid gland

**thyroxine (tetraiodothyronine,  $T_4$ )** thyroid hormone containing 4 iodines that controls the basal metabolic rate

**triiodothyronine ( $T_3$ )** thyroid hormone containing 3 iodines controls the basal metabolic rate

**up-regulation** an increase in the number of hormone receptors in response to increased hormone levels

## CHAPTER SUMMARY

### 28.1 Types of Hormones

There are three basic types of hormones: lipid-derived, amino acid-derived, and peptide. Lipid-derived hormones are structurally similar to cholesterol and include steroid hormones such as estradiol and testosterone. Amino acid-derived hormones are relatively small molecules and include the adrenal hormones epinephrine and norepinephrine. Peptide hormones are polypeptide chains or proteins and include the pituitary hormones, antidiuretic hormone (vasopressin), and oxytocin.

### 28.2 How Hormones Work

Hormones cause cellular changes by binding to receptors on target cells. The number of receptors on a target cell can increase or decrease in response to hormone activity. Hormones can affect cells directly through intracellular hormone receptors or indirectly through plasma membrane hormone receptors.

Lipid-derived (soluble) hormones can enter the cell by diffusing across the plasma membrane and binding to DNA to regulate gene transcription and to change the cell's activities by inducing production of proteins that affect, in general, the long-term structure and function of the cell. Lipid insoluble hormones bind to receptors on the plasma membrane surface and trigger a signaling pathway to change the cell's activities by inducing production of various cell products that affect the cell in the short-term. The hormone is called a first messenger and the cellular component is called a second messenger. G-proteins activate the second messenger (cyclic AMP), triggering the cellular response. Response to hormone binding is amplified as the signaling pathway progresses. Cellular responses to hormones include the production of proteins and enzymes and altered membrane permeability.

### 28.3 Regulation of Body Processes

Water levels in the body are controlled by antidiuretic hormone (ADH), which is produced in the hypothalamus and triggers the reabsorption of water by the kidneys. Underproduction of ADH can cause diabetes insipidus. Aldosterone, a hormone produced by the adrenal cortex of the kidneys, enhances  $\text{Na}^+$  reabsorption from the extracellular fluids and subsequent water reabsorption by diffusion. The renin-angiotensin-aldosterone system is one way that aldosterone release is controlled.

The reproductive system is controlled by the gonadotropins follicle-stimulating hormone (FSH) and luteinizing hormone (LH), which are produced by the pituitary gland. Gonadotropin release is controlled by the hypothalamic hormone gonadotropin-releasing hormone (GnRH). FSH stimulates the maturation of sperm cells in males and is inhibited by the hormone inhibin, while LH stimulates the production of the androgen testosterone. FSH stimulates egg maturation in females, while LH stimulates the production of estrogens and progesterone. **Estrogens** are a group of steroid hormones produced by the ovaries that trigger the development of secondary sex characteristics in females as well as control the maturation of the ova. In females, the pituitary also produces prolactin, which stimulates milk production after childbirth, and oxytocin, which stimulates uterine contraction during childbirth and milk let-down during suckling.

Insulin is produced by the pancreas in response to rising blood glucose levels and allows cells to utilize blood glucose and store excess glucose for later use. Diabetes mellitus is caused by reduced insulin activity and causes high blood glucose levels, or hyperglycemia. Glucagon is released by the pancreas in response to low blood glucose levels and stimulates the breakdown of glycogen into glucose, which can be used by the body. The body's basal metabolic rate is controlled by the thyroid hormones thyroxine ( $T_4$ ) and triiodothyronine ( $T_3$ ). The anterior pituitary produces thyroid stimulating hormone (TSH), which controls the release of  $T_3$  and  $T_4$  from the thyroid gland. Iodine is necessary in the production of thyroid hormone, and the lack of iodine can lead to a condition called goiter.

Parathyroid hormone (PTH) is produced by the parathyroid glands in response to low blood  $\text{Ca}^{2+}$  levels. The parafollicular cells of the thyroid produce calcitonin, which reduces blood  $\text{Ca}^{2+}$  levels. Growth hormone (GH) is produced by the anterior pituitary and controls the growth rate of muscle and bone. GH action is indirectly mediated by insulin-like growth factors (IGFs). Short-term stress causes the hypothalamus to trigger the adrenal medulla to release epinephrine and norepinephrine, which trigger the fight or flight response. Long-term stress causes the hypothalamus to trigger the anterior pituitary to release adrenocorticotrophic hormone (ACTH), which causes the release of corticosteroids, glucocorticoids, and mineralocorticoids, from the adrenal cortex.

### 28.4 Regulation of Hormone Production

Hormone levels are primarily controlled through negative feedback, in which rising levels of a hormone inhibit its further release. The three mechanisms of hormonal release are humoral stimuli, hormonal stimuli, and neural stimuli. Humoral

stimuli refers to the control of hormonal release in response to changes in extracellular fluid levels or ion levels. Hormonal stimuli refers to the release of hormones in response to hormones released by other endocrine glands. Neural stimuli refers to the release of hormones in response to neural stimulation.

## 28.5 Endocrine Glands

The pituitary gland is located at the base of the brain and is attached to the hypothalamus by the infundibulum. The anterior pituitary receives products from the hypothalamus by the hypophyseal portal system and produces six hormones. The posterior pituitary is an extension of the brain and releases hormones (anti-diuretic hormone and oxytocin) produced by the hypothalamus.

The thyroid gland is located in the neck and is composed of two lobes connected by the isthmus. The thyroid is made up of follicle cells that produce the hormones thyroxine and triiodothyronine. Parafollicular cells of the thyroid produce calcitonin. The parathyroid glands lie on the posterior surface of the thyroid gland and produce parathyroid hormone.

The adrenal glands are located on top of the kidneys and consist of the renal cortex and renal medulla. The adrenal cortex is the outer part of the adrenal gland and produces the corticosteroids, glucocorticoids, and mineralocorticoids. The adrenal medulla is the inner part of the adrenal gland and produces the catecholamines epinephrine and norepinephrine.

The pancreas lies in the abdomen between the stomach and the small intestine. Clusters of endocrine cells in the pancreas form the islets of Langerhans, which are composed of alpha cells that release glucagon and beta cells that release insulin.

Some organs possess endocrine activity as a secondary function but have another primary function. The heart produces the hormone atrial natriuretic peptide, which functions to reduce blood volume, pressure, and  $\text{Na}^+$  concentration. The gastrointestinal tract produces various hormones that aid in digestion. The kidneys produce renin, calcitriol, and erythropoietin. Adipose tissue produces leptin, which promotes satiety signals in the brain.

## REVIEW QUESTIONS

**1.** Although most types of hormones are lipid insoluble, there are some that are lipid soluble and can therefore diffuse through plasma membranes. What class of hormones can diffuse through plasma membranes?

- a. lipid-derived hormones
- b. amino acid-derived hormones
- c. peptide hormones
- d. glycoprotein

**2.** Mary produces relatively low amounts of estradiol and cortisol, but is able to produce proper amounts of other hormones such as thyroxine and insulin. Identify the chemical class of hormones that Mary has difficulty producing.

- a. lipid-derived hormones
- b. amino acid-derived hormones
- c. peptide hormones
- d. glycoprotein hormones

**3.** An endocrinologist is a physician whose specialty is treating endocrine-related disorders. Which of the following diseases would be monitored and treated by an endocrinologist?

- a. schizophrenia
- b. Alzheimer's disease
- c. Parkinson's disease
- d. Grave's disease

**4.** Robert underwent a test to determine if he was diabetic.

Within 1.5 hours of eating, his blood glucose was normal. What can be determined from these results?

- a. The pancreas is over-producing insulin.
- b. The pancreas is under-producing insulin.
- c. The pancreas is producing an adequate amount of insulin.
- d. The pancreas is not producing any insulin.

**5.** The hormone that triggers the flight-or-fight response, epinephrine, is derived from tyrosine, and the hormone that regulates circadian rhythms, melatonin, is derived from tryptophan. What class of hormone are these?

- a. lipid-derived hormones
- b. amino acid-derived hormones
- c. peptide hormones
- d. glycoprotein hormones

**6.** A newly discovered hormone contains four amino acids linked together. Identify the chemical class under which this hormone would be classified.

- a. lipid-derived hormones
- b. amino acid-derived hormones
- c. peptide hormones
- d. glycoprotein hormones

**7.** Changes in the body can be mediated by direct or indirect mechanisms. What facilitate(s) direct mediation of change by hormones?

- a. intracellular hormone receptors  
b. cell surface receptors  
c. up-regulation  
d. down-regulation
- 8.** How do thyroid hormones stimulate metabolic activity throughout the body?
- Specialized thyroid-receiving tissues are located throughout the body.
  - Blood circulation stimulates metabolic activity.
  - Different tissues have thyroid hormone receptors.
  - Thyroid tissue is located throughout the body.
- 9.** Different hormones have different roles in cell signaling. Identify the term for a hormone that initiates cell-signaling pathways.
- intracellular hormone receptor
  - cell surface receptor
  - first messenger
  - second messenger
- 10.** A new antagonist molecule has been discovered that binds to and blocks plasma membrane receptors. Describe the affect this antagonist will have on testosterone, which is a steroid hormone.
- This molecule will block testosterone from binding to its receptor.
  - This molecule will block testosterone from activating cAMP signaling.
  - This molecule will increase testosterone-mediated signaling.
  - This molecule will not affect testosterone-mediated signaling.
- 11.** Identify what triggers a reduction in the number of receptors if there are elevated hormone levels.
- intracellular hormone receptors
  - cell surface receptors
  - up-regulation
  - down-regulation
- 12.** Consuming certain products cause a change in urine output. This likely occurs because these products \_\_\_\_\_.
- inhibits ADH release
  - stimulates ADH release
  - inhibits TSH release
  - stimulates TSH release
- 13.** FSH and LH release from the anterior pituitary is stimulated by \_\_\_\_\_.
- a. TSH  
b. GnRH  
c.  $T_3$   
d. PTH
- 14.** What hormone is produced by beta cells of the pancreas?
- $T_3$
  - glucagon
  - insulin
  - $T_4$
- 15.** When blood calcium levels are low, PTH stimulates \_\_\_\_\_.
- excretion of calcium from the kidneys
  - excretion of calcium from the intestines
  - osteoblasts
  - osteoclasts
- 16.** What enzyme is released when blood pressure drops and stimulates a cascade of events for hormones that promote water reabsorption?
- aldosterone
  - renin
  - antidiuretic hormone
  - osmoreceptors
- 17.** Drinking alcoholic beverages causes an increase in urine output. This most likely occurs because alcohol \_\_\_\_\_.
- inhibits antidiuretic hormone release
  - stimulates antidiuretic hormone release
  - inhibits parathyroid hormone release
  - stimulates parathyroid hormone release
- 18.** The hypothalamus is responsible for a diverse array of metabolic and autonomic nervous system functions. For example, the hypothalamus produces \_\_\_\_\_ during puberty.
- follicle-stimulating hormone
  - luteinizing hormone
  - inhibin
  - gonadotropin-releasing hormone
- 19.** Sandra wants to get pregnant but learns that she does not produce a sufficient amount of prolactin. Describe how her reproductive abilities will be affected.
- Her uterus will not contract during childbirth.
  - She will not ovulate.
  - Her body will not be prepared for pregnancy.
  - She will be unable to produce milk.
- 20.** Different hormones are released as short-term and

long-term stress responses. \_\_\_\_ is/are released as a long-term stress response.

- a. Epinephrine
- b. Parathyroid hormone
- c. Corticosteroids
- d. T3 and T4

**21.** When blood calcium levels are low, parathyroid hormone (PTH) stimulates \_\_\_\_\_.

- a. excretion of calcium from the kidneys
- b. excretion of calcium from the intestines
- c. osteoblasts
- d. osteoclasts

**22.** If you overproduce insulin after eating a meal, you may experience \_\_\_\_\_.

- a. diabetes mellitus
- b. diabetes insipidus
- c. hyperglycemia
- d. hypoglycemia

**23.** Charlie has been diagnosed with acromegaly. Identify the symptom(s) that he may have.

- a. symmetric body formation
- b. excessive body growth
- c. enlarged hand, feet, and face bones
- d. weak bones and nervous system impairment

**24.** What hormone is produced by beta cells of the pancreas in response to elevated blood glucose levels?

- a. T3
- b. glucagon
- c. insulin
- d. T4

**25.** There are substantially more hormones that undergo a negative feedback loop than a positive feedback loop. Which of the following hormones is regulated by a positive feedback loop?

- a. thyroxine
- b. oxytocin
- c. triiodothyronine
- d. insulin

**26.** Describe what occurs if a hormone is released by a hormonal stimulus.

- a. Hormone release is stimulated by the nervous system.
- b. Hormone release is stimulated by change in the blood.
- c. Hormone release is stimulated by the external environment.
- d. Hormone release is stimulated by another hormone.

**27.** A rise in blood glucose levels triggers release of insulin from the pancreas. What type of stimulus initiates insulin release?

- a. humoral
- b. hormonal
- c. neural
- d. negative

**28.** Why is the release of thyroid stimulating hormone (TSH) considered a hormonal stimulus?

- a. TSH production is triggered by the nervous system.
- b. TSH production is triggered by blood ion concentration change.
- c. TSH triggers epinephrine production.
- d. TSH triggers the production of T3 and T4.

**29.** What kind of stimulus promotes hormone release in response to ion concentrations in the blood?

- a. humoral stimulus
- b. hormonal stimulus
- c. neural stimulus
- d. negative stimulus

**30.** Which of the following endocrine glands control kidney function?

- a. thyroid glands
- b. adrenal glands
- c. gonads
- d. pancreas

**31.** The islets of Langerhans are clusters of endocrine cells in the pancreas. What is the function of the islets of Langerhans?

- a. regulate circadian rhythms
- b. regulate secondary sex characteristics
- c. regulate blood calcium levels
- d. regulate blood glucose

**32.** What do adipose tissues release after a meal?

- a. erythropoietin
- b. leptin
- c. atrial natriuretic peptide
- d. gastrin

33. Describe how the kidneys and adrenal cortex work together to increase blood volume.

- a. They adrenal cortex produces renin, which affects aldosterone secretion by the kidneys.
- b. The kidneys produce renin, which affects aldosterone secretion by the adrenal cortex.
- c. They kidneys produce calcitrol, which affects renin secretion by the adrenal cortex.
- d. They kidneys produce calcitrol, which affects aldosterone secretion by the adrenal cortex.

## CRITICAL THINKING QUESTIONS

35. Although there are many different hormones in the human body, they can be divided into three classes based on their chemical structure. Explain these classes and give one factor that distinguishes each.

- a. The classes are peptide hormones, which are water insoluble, and amino acid-derived and lipid-derived hormones, which are water soluble.
- b. The classes are lipid-derived hormones, which are water insoluble, and amino acid-derived and peptide hormones, which are water soluble.
- c. The classes are lipid-derived hormones, which are water soluble, and amino acid-derived and peptide hormones, which are water insoluble.
- d. The classes are amino acid-derived hormones, which are water insoluble, and lipid-derived and peptide hormones, which are water soluble.

36. Explain how hormones promote homeostasis in the body.

- a. Hormones increases cell activity by binding to the receptors present in the cell.
- b. Hormones facilitate communication between cells present at very distant locations in the body.
- c. Hormones facilitate communication between cells at any distance in the body.
- d. Hormones mediate changes by directly binding to the intracellular hormone receptors.

37. A new hormone is discovered that binds to receptors on the target cell surface. Describe the chemical class of hormone that this hormone could belong to and explain how you could discern the exact class.

34. The anterior pituitary produces several hormones. Identify which of the following hormones is not produced by the anterior pituitary.

- a. oxytocin
- b. growth hormone
- c. prolactin
- d. thyroid-stimulating hormone

a. It belongs to the class lipid-derived or peptide hormone as it is water insoluble and thus requires a cell surface receptor. The exact class can be determined on the basis of the hormone's size.

b. It belongs to the class amino acid derived hormones as it is lipid insoluble and thus requires a cell surface receptor. This can be discerned by determining the exact structure of the hormone.

c. It belongs to the class lipid-derived or peptide hormone as it is water insoluble and thus requires a cell surface receptor. This can be discerned by determining the exact structure of the hormone.

d. It belongs to the class amino acid derived or peptide hormone as it is lipid insoluble and thus requires a cell surface receptor. The exact class can be determined on the basis of the hormone's size.

38. Explain why hormones are able to travel through the body but only affect certain cells.

- a. Hormones only affect cells that have plasma membrane receptors.
- b. Hormones only affect cells that have corresponding hormone receptors.
- c. Hormones only affect cells that have intracellular receptors.
- d. Hormones only affect cells that are infected.

39. Discuss the important functions of hormone receptors.

- a. Hormone receptors can induce cell-signaling pathways and mediate changes in target cells in the presence of hormones.
- b. Hormone receptors can mediate changes in target cells and act as transcription regulators in the presence of hormones.
- c. Hormone receptors can induce cell-signaling pathways and act as transcription regulators in the presence of hormones.
- d. Hormone receptors can mediate changes in target cells and can stimulate signaling pathways in the presence of hormones.

**40.** Describe how cell surface receptors and intracellular receptors are similar and how they differ.

- a. Both are types of hormone receptors at target cells. Cell surface receptors facilitate indirect mediation, whereas intracellular receptors facilitate direct mediation.
- b. Both are types of hormone receptors at target cells. Cell surface receptors facilitate direct mediation, whereas intracellular receptors facilitate indirect mediation.
- c. Both reside in the cytoplasm or in the nucleus. Cell surface receptors facilitate indirect mediation, whereas intracellular receptors facilitate direct mediation.
- d. Both reside in the cytoplasm or in the nucleus. Cell surface receptors facilitate direct mediation, whereas intracellular receptors facilitate indirect mediation.

**41.** Explain why drinking alcohol often results in dehydration.

- a. Drinking alcohol reduces antidiuretic hormone production, which is a hormone that helps retain water.
- b. Drinking alcohol increases antidiuretic hormone production, which is a hormone that helps with water loss.
- c. Drinking alcohol reduces thyroid stimulating hormone production, which is a hormone that helps retain water.
- d. Drinking alcohol increases thyroid stimulating hormone production, which is a hormone that helps with water loss.

**42.** Describe how gonadotropin-releasing hormone production is controlled by a negative feedback loop.

- a. Gonadotropin-releasing hormone decreases production of follicle stimulating hormone, which decreases hormone production in the gonads. An increase in gonad hormone production then inhibits gonadotropin-releasing hormone production.
- b. Gonadotropin-releasing hormone stimulates production of follicle stimulating hormone, which regulates hormone production in the gonads. An increase in gonad hormone production then inhibits gonadotropin-releasing hormone production.
- c. Gonadotropin-releasing hormone decreases production of luteinizing hormone, which decreases hormone production in the gonads. An increase in gonad hormone production then inhibits gonadotropin-releasing hormone production.
- d. Gonadotropin-releasing hormone stimulates production of luteinizing hormone, which regulates hormone production in the gonads. An increase in gonad hormone production then inhibits gonadotropin-releasing hormone production.

**43.** Explain where insulin is stored and under what circumstances it is released.

- a. It is stored in the pancreas and is released as glucose increases in the blood to enhance the rate of glucose uptake.
- b. It is stored in the liver and is released as glucose increases in the blood to enhance the rate of glucose uptake.
- c. It is stored in the pancreas and is released as glucose levels decrease in blood to decrease the rate of glucose uptake.
- d. It is stored in the liver and is released as glucose levels decrease in the blood to decrease the rate of glucose uptake.

**44.** Ralph is always thirsty and recently learned that he synthesizes mutated antidiuretic hormone (ADH). Discuss why Ralph would be at higher risk for diabetes insipidus.

- a. ADH helps in the loss of water. Overproduction of ADH would cause improper functioning of kidneys.
- b. Underproduction of ADH inhibits the release of aldosterone that would cause improper functioning of kidneys.
- c. ADH helps retain water. Underproduction of ADH would cause improper functioning of kidneys.
- d. ADH helps in retaining electrolytes. Underproduction of ADH causes improper functioning of kidneys.

**45.** Describe how stress promotes water retention, which can lead to weight gain.

- a. Stress decreases osmolality, which increases antidiuretic hormone secretion. Antidiuretic hormone helps retain water.
- b. Stress increases osmolality, which increases antidiuretic hormone secretion. Antidiuretic hormone helps retain water.
- c. Stress increases osmolality, which decreases antidiuretic hormone secretion. Antidiuretic hormone helps with water loss.
- d. Stress decreases osmolality, which decreases antidiuretic hormone secretion. Antidiuretic hormone helps with water loss.

**46.** Identify which type of feedback mechanism primarily controls hormone production and release and explain why this occurs.

- a. Positive feedback loop to help maintain the water concentration in the body.
- b. Negative feedback loop to help maintain the water concentration in the body.
- c. Negative feedback loop to help maintain proper bodily functions within a specific range.
- d. Positive feedback loop to help maintain proper bodily functions within a specific range.

**47.** Compare and contrast humoral and hormonal stimuli.

- a. Both humoral and hormonal stimuli release proteins. Humoral stimuli are hormones that stimulate other hormones, whereas hormonal stimuli are extracellular fluid-related stimuli.
- b. Both humoral and hormonal stimuli release proteins. Humoral stimuli are extracellular fluid-related stimuli, whereas hormonal stimuli are hormones that stimulate other hormones.
- c. Both humoral and hormonal stimuli release hormones. Humoral stimuli are extracellular fluid-related stimuli, whereas hormonal stimuli are hormones that stimulate other hormones.
- d. Both humoral and hormonal stimuli release hormones. Humoral stimuli are hormones that stimulate other hormones, whereas hormonal stimuli are extracellular fluid-related stimuli.

**48.** Explain why it would be problematic if most hormones were regulated by a positive feedback loop.

- a. Excessive production of actions would be stimulated by hormones such as growth and blood glucose levels.
- b. Production of actions would be reduced by hormones such as growth and blood glucose levels.
- c. Inhibition of GnRH production by increase in gonad hormone levels.
- d. Inhibition of release of insulin by decrease in blood glucose concentrations.

**49.** Identify what aldosterone regulates, and explain how it is stimulated.

- a. Aldosterone regulates the amount of water excreted by the kidneys and causes direct water reabsorption from the kidney tubules. It is stimulated by decreased water concentration in blood, or increased amounts of blood potassium.
- b. Aldosterone regulates sodium concentrations in urine, sweat, the pancreas, and saliva. It is stimulated by decreased blood sodium ion concentrations, blood volume, or blood pressure, or increased amounts of blood potassium.
- c. Aldosterone regulates calcium concentrations in urine, saliva and the pancreas. It is stimulated by decreased blood calcium ion concentrations, blood pressure, blood volume, or increased amounts of blood potassium.
- d. Aldosterone regulates blood glucose levels by stimulating the breakdown of glycogen to glucose. It is stimulated by decreased concentrations of glucose levels in blood, blood volume, or blood pressure.

**50.** Discuss which aspect of the endocrine system often renders extremely thin females less fertile. Explain why this occurs.

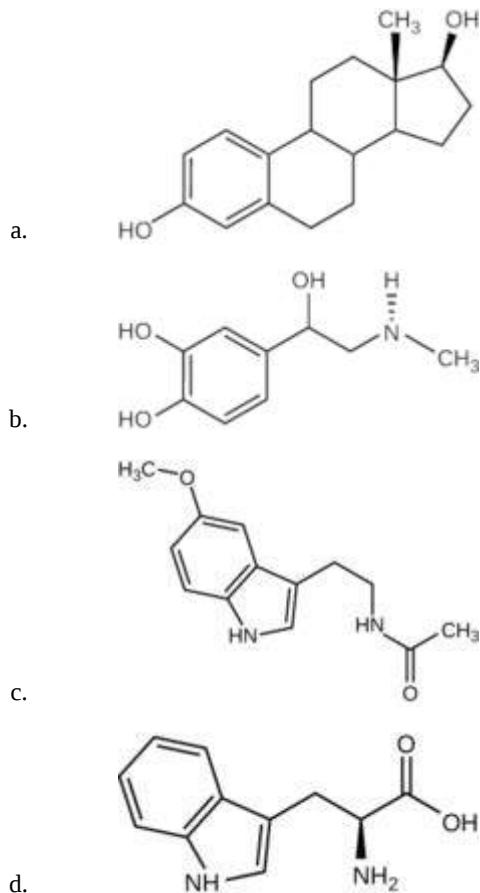

- a. Adipose tissue releases leptin, which is needed to produce gonadotropin-releasing hormone and gonadotropin. Leptin cannot be released without sufficient body fat.
- b. Adipose tissue releases thymosins needed to produce gonadotropin-releasing hormone and gonadotropin. Thymosins cannot be produced without sufficient body fat.
- c. Adipose tissue releases leptin needed to produce gonadotropin-releasing hormone and gonadotropin. Leptins cannot be produced in the absence of body fat.
- d. Adipose tissue releases leptin needed to produce estrogens and progesterone. Leptin cannot be released without sufficient body fat.

**51.** The adrenal medulla secretes two types of hormones. Identify what is secreted and describe their functions.

- a. They secrete cortisol and aldosterone, which increase heart rate, breathing rate, muscle contractions, blood pressure, and blood glucose as short-term stress response.
- b. They secrete epinephrine and norepinephrine, which increase heart rate, breathing rate, muscle contractions, blood pressure, and blood glucose as long-term stress response.
- c. They secrete cortisol and aldosterone, which increase heart rate, breathing rate, muscle contractions, blood pressure, and blood glucose as long-term stress response.
- d. They secrete epinephrine and norepinephrine, which increase heart rate, breathing rate, muscle contractions, blood pressure, and blood glucose as short-term stress response.

## TEST PREP FOR AP® COURSES

**52.** There are three types of hormones based on chemical structure: lipid-derived, amino acid-derived, and peptide hormones. Identify the hormone that is lipid-derived.

**53.** Hormones are essential for facilitating communication between cells, which can help maintain homeostasis within the body. Explain how hormones facilitate communication on a molecular level.

- a. A hormone is released in response to a stimulus, travels through the body, and then binds to receptors of the target cell to illicit a response.
- b. A hormone is released from the pituitary gland in response to a stimulus, travels through the body, and then binds to a receptor of a target cell to illicit response.
- c. A hormone is released in response to a stimulus, travels through the body, and then binds to receptors to stimulate the signaling pathway.
- d. A hormone is released in response to a stimulus, travels through the body and then binds to the intracellular receptors of target cells to illicit a response.

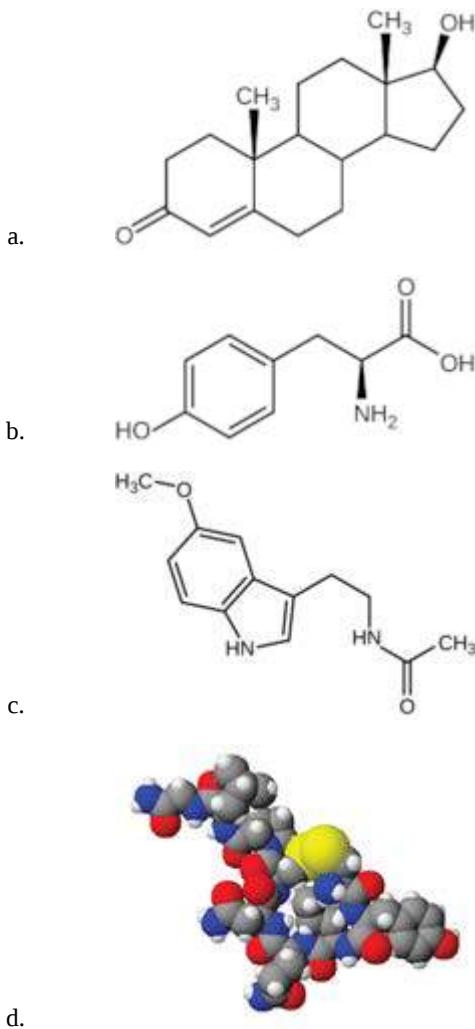

**54.** Steroid hormones are known to circulate in the blood longer than peptide hormones. Describe why this occurs.

- a. Peptide hormones cannot pass through cell membranes.
- b. Steroid hormones are water insoluble.
- c. Peptide hormones are water soluble.
- d. Steroid hormones cannot pass through cell membranes.

**55.** Lipid-derived hormones, such as steroid hormones, utilize intracellular receptors, whereas peptide and amino acid-derived hormones utilize cell surface receptors. Discuss why these hormones utilize different types of receptors.

- a. Lipid-derived hormones have receptors located in the nucleus, and thus utilize intracellular receptors, whereas peptide and amino acid-derived hormones have receptors only on the surface of the cell.
- b. Lipid-derived hormones can permeate the plasma membrane and thus utilize intracellular receptors. Peptide and amino acid- derived hormones are lipid insoluble and thus require cell surface receptors.
- c. Lipid-derived hormones can permeate plasma membranes as they need to remain in circulation for a longer duration. Peptide and amino acid-derived hormones are lipid insoluble and need surface receptors.
- d. Lipid-derived hormones can permeate plasma membranes and thus utilize intracellular receptors. Some peptide and amino acid-derived hormones can cross the membrane but most are lipid insoluble and thus require cell surface receptors.

**56.** There are three types of hormones based on chemical structure: lipid-derived, amino acid-derived, and peptide hormones. Identify the peptide hormone.

**57.** Cellular activity can vary based on sensitivity to hormones, and cellular activity can therefore either be up-regulated or down-regulated by those hormones. What would likely cause a greater response from cells that are controlled by a hormone?

- a. hormone levels increase and the number of target cell receptors increase
- b. hormone levels decrease and the number of target cell receptors increase
- c. hormone levels increase and the number of target cell receptors decrease
- d. hormone levels decrease and the number of target cell receptors decrease

**58.** Determine what kind of hormone is undergoing binding in this figure and explain how you know.

- a. A lipid-derived hormone because it is fat insoluble and therefore able to bind to receptors on the outer surface of the plasma membrane.
- b. A lipid-derived hormone because it is fat soluble and therefore able to pass through the cell membrane to reach intracellular receptors.
- c. A polypeptide-derived hormone because it is fat soluble and therefore able to pass through the cell membrane to reach intracellular receptors.
- d. A polypeptide-derived hormone because it is fat insoluble and therefore binds to receptors on the outer surface of the plasma membrane.

**59.** In this figure, what kind of hormone is bound to the target cell receptor?

- a. steroid
- b. lipid-derived
- c. estradiol
- d. amino acid-derived

**60.** Blood pressure and blood volume are increased by the production of the hormones antidiuretic hormone (ADH) and aldosterone. Describe how renin promotes release of ADH and aldosterone.

- a. Renin cleaves angiotensinogen.
- b. Renin directly simulates ADH and aldosterone production.
- c. Renin produces angiotensin II.
- d. Angiotensin I is converted to angiotensin II.

**61.** Antidiuretic hormone (ADH) is essential for water regulation in the kidneys. Once released from the pituitary, ADH travels through to the kidneys. Explain how ADH promotes water reabsorption.

- a. ADH initiates a series of events that lead to release of more vasopressin hormone in the kidney, leading to the movement of water out of kidneys
- b. ADH initiates a series of events that lead to temporary insertion of aquaporins in the kidney, through which water moves in the kidney.
- c. ADH initiates a series of events leading to temporary insertion of aquaporins in the kidney, through which water moves out of the kidneys.
- d. ADH initiates a series of events that leads to the movement of water out of the kidneys through simple diffusion.

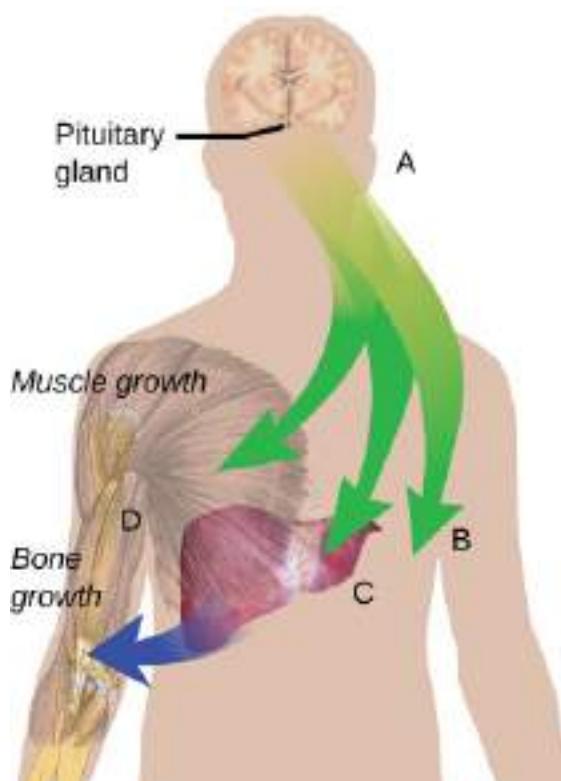

**62.** David, an athlete, wants to enhance his baseball performance by taking erythropoietin. Identify what David is trying to change.

- a. build more muscle
- b. improve endurance
- c. reduce fertility
- d. decrease need to urinate

**63.** Some athletes may want to take synthetic hormones to improve their performance in their given sport. However, the use of certain synthetic hormones is banned in many professional sports. Explain why synthetic hormones are often banned.

- a. There can be severe side effects such as insomnia, depression and prostate enlargement. These side effects are often severe and irreversible.
- b. There can be severe side effects such as impaired heart function, testicular atrophy, and prostate enlargement. These side effects can be cured through surgeries.
- c. There can be severe side effects such as impaired heart function, testicular atrophy, and prostate enlargement. These are often severe and irreversible.
- d. There can be severe side effects such as insomnia, depression and prostate enlargement. These side effects can be cured through surgeries.

**64.**

This figure shows how growth hormone communicates with cells to promote muscle and bone growth. Identify

growth hormone's exact role.

- a. inhibits growth hormone-inhibiting hormone release
- b. stimulates growth hormone-releasing hormone release
- c. breaks down glycogen
- d. activates insulin-like growth factors

**65.** Growth hormone helps promote growth by accelerating the rate of protein synthesis. Describe how growth hormone switches the energy source of most cells.

- a. Growth hormone is able to break down triglycerides through lipogenesis. When triglycerides are released, most tissues switch to fatty acids as energy sources.
- b. Growth hormone is able to break down triglycerides through lipolysis. When triglycerides are released, most tissues switch to fatty acids as an energy source.
- c. Growth hormone is able to break down triglycerides through lipolysis. When triglycerides are released, most tissues switch to glucose as an energy source.
- d. Growth hormone is able to break down triglycerides through lipogenesis. When triglycerides are released, most tissues switch to glucose as an energy source.

**66.** Positive feedback loops are rare in the endocrine system but some do exist. Identify an example of a positive feedback loop.

- a. Insulin facilitates decrease of blood sugar levels.
- b. Oxytocin release stimulates milk release.
- c. Increased blood calcium levels halt PTH production.
- d. Increased amounts of T3 and T4 inhibit further production.

**67.** Although positive feedback loops are rare in the endocrine system, they are present in childbirth. Explain how childbirth is controlled by a positive feedback loop.

- a. When a child pushes on the cervix, a signal is sent to stimulate oxytocin release, which stimulates more contractions. This promotes more oxytocin release that allows the child to be pushed through the birth canal.
- b. When a child pushes on the cervix, a signal is sent to stimulate oxytocin release, which stimulates contractions. This promotes release of progesterone that allows the child to be pushed through the birth canal.
- c. When a child pushes on the cervix, a signal is sent to stimulate prolactin release, which stimulates more contractions. This promotes release of more prolactin that allows the child to be pushed through the birth canal.
- d. When a child pushes on the cervix, a signal is sent to stimulate progesterone release, which stimulates contractions. This promotes release of oxytocin that allows the child to be pushed through the birth canal.

**68.** Osmoreceptors are essential for monitoring water concentrations within the body. Describe how osmoreceptors complete this task.

- a. Osmoreceptors insert aquaporins in the kidneys.
- b. Osmoreceptors signal increase sodium reabsorption.
- c. Osmoreceptors detect when blood electrolyte levels change.
- d. Osmoreceptors signal increased sodium reabsorption.

**69.** Laura has Type 1 diabetes and her body cannot properly produce insulin in response to elevated blood glucose levels. Identify which type of stimulus Laura is unable to respond to.

- a. humoral
- b. hormonal
- c. neural
- d. negative

**70.** Terry recently gained weight and has been more tired than usual. Terry's doctor suggested that he might not produce enough thyroid-stimulating hormone (TSH). Explain why a TSH deficiency could cause Terry's weight gain and fatigue.

- a. Without TSH, there would be excessive production of T3 and T4 leading to a high metabolic rate, causing weight gain and fatigue.
- b. Without TSH, there would be excessive production of T3 and T4 leading to a low metabolic rate, causing weight gain and fatigue.
- c. Without TSH, T3 and T4 cannot be properly produced, leading to a high metabolic rate, causing weight gain and fatigue.
- d. Without TSH, T3 and T4 cannot be properly produced, leading to a low metabolic rate, causing weight gain and fatigue.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**72.** Many hormones repress or enhance protein expression by binding to transcription factors called nuclear receptors. Other hormones regulate processes by binding to cell surface receptors that induce cell signaling cascades.

A. **Represent** these two different processes for cell-cell communication by creating a flow chart showing the direction of information in a process regulating homeostasis such as the control of blood sugar or water loss. Annotate your diagram to **describe** the key elements of each step in the particular example that you choose.

B. **Justify the claim** that a developmental process is more likely to involve nuclear receptors, while regulation of metabolism is more likely to involve cell surface receptors.

The lancelet is a chordate, fish-like filter feeder that buries itself in marine sands. Their ancestors and vertebrates diverged approximately 500 million years ago. Lancelet and human are members of a superphylum of animals with bilateral symmetry, *Deuterostomia*. In one model of animal evolution, the other superphylum, *Protostomia*, includes fruit fly and nematode. In an alternative model, insects are included with lancelet and human in a superphylum called the *Coelomata*, and the nematode is separate. Molecular studies of fruit fly, lancelet, human, and nematode show that homologous genes, when present, are strongly conserved. For example, the genes for the receptors of germ cell nuclear factor (GCNF) and retinoids, hormones that regulate cellular differentiation during development, are present in each species.

Homologous genes for nuclear receptor estrogen and thyroid hormone are present in lancelet and human but missing in nematode and fruit fly. Genes for the vitamin D receptor are absent in fruit fly but are present in the other species.

Many neuropeptide hormones found in human, fruit fly and nematode such as GnRH (gonadotropin-releasing hormone) and the gonadotropins luteinizing and follicle stimulating hormones (LH and FSH) have not been found in lancelet. However, genes for the cell surface receptors activated by these hormones are expressed. The same is true for many different hormones and their corresponding

**71.** Marcus experienced nervous system damage in a car accident. Identify which of the following endocrine-related body functions will be most likely impaired as a result.

- a. ability to lower blood glucose levels
- b. fight-or-flight response
- c. urine production
- d. body heat regulation

receptors. A large number of such “orphan” nuclear receptors have been reported in animals where there is no evidence of the presence of the hormone to which they bind.

C. **Analyze** these data (a table to organize the data is suggested) for supporting evidence of the alternative superphylum, *Coelomata*. Consider:

- separate selection of signaling molecules and the proteins that detect them
- constitutive (always transcribed) expression
- the possible effect of gene deletion

D. **Evaluate** the legitimacy of a claim that a hormone is not present although the receptor for that hormone has been found.

Genes for receptors and the hormones to which they bind are often found on different chromosomes and have co-evolved. Other ligands may have an affinity for orphaned receptors. By understanding the three-dimensional shape of the ligand binding site of a nuclear receptor, new drugs can be developed to match the site and regulate expression when the endocrine system fails. Even greater flexibility in drug design is allowed when small molecules, called positive (PAM) and negative (NAM) allosteric modulators, change the shape of the ligand binding site. The receptors for follicle stimulating hormone (FSH) and luteinizing hormone (LH) were subjects in a drug discovery program using PAMs and NAMs (Nataraja et al., *Frontiers in Endocrinology*, 6, 2015).

E. **Explain** how the refinement of nuclear receptor by attachment of a molecule other than the ligand of the receptor can increase the level of expression of genes targeted by the transcription factor.

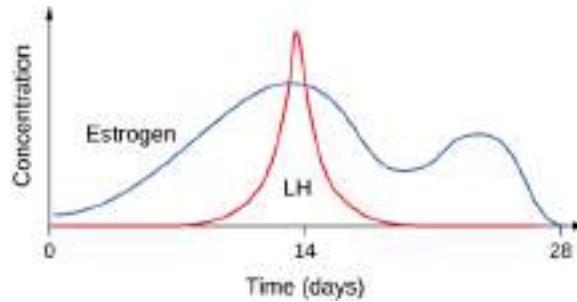

**73.** Gonadotrophin-releasing hormone (GnRH) stimulates the production of follicle-stimulating hormone (FSH) and luteinizing hormone (LH). The concentration of these hormones over time in females regulates the menstrual cycle. GnRH expressing neurons (GEN) are scattered throughout the forebrain and hypothalamus and secrete into ducts leading to the pituitary gland, causing the

secretion of FSH and LH into the bloodstream.  $\text{Ca}^{+2}$  concentrations oscillate in time, changing the electric membrane potential of the GnRH neurons, GEN. The period of the oscillation is only a few seconds in duration. The mechanism controlling the oscillating membrane potential is unknown, but during maturation the frequency of the oscillations of the  $\text{Ca}^{+2}$  concentration in the GEN increases.

A. **Explain** how the absence of direct contact among the GnRH neurons and the coordinated release of FSH and LH suggest another timing mechanism.

An association of high concentrations of anti-Mullerian hormone (AMH) and elevated LH levels among women with a common reproductive disorder called polycystic ovary syndrome (PCOS) caused investigators to study the effects of AMH on membrane potentials of GnRH expressing neurons. The researchers (Cimino et al., *Nature Communications*, 7, 2016) found that very small concentrations of AMH initiated oscillations.

B. The graph illustrates the time dependence of LH and estrogen in the blood of a female. A goal of research in human reproductive physiology is to construct a model that accounts for the spike in luteinizing hormone at approximately 14 days. **Predict** how a positive feedback loop involving the release of a hormone such as AMH could be used to account for this response. **Explain** why estrogen is probably not a good candidate for use in this model.

**Figure 28.21**

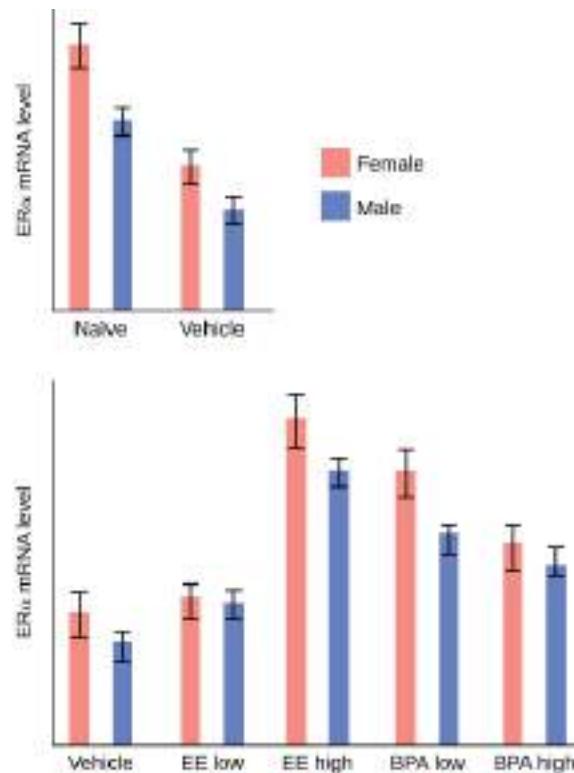

FSH and LH inhibit production of GnRH. Exposure of ovarian follicles to high levels of FSH and LH causes the follicle to rupture, releasing an oocyte to the oviduct. Birth control drugs suppress the LH surge by maintaining a constant blood concentration of progesterone (PG). After 40 years of use, the mechanism of suppression is still unknown. However, we do know that during pregnancy progesterone levels remain elevated and that cells in both the pituitary gland and GnRH expressing neurons (GEN) have progesterone nuclear receptors (PGR) that act as transcription factors to either i) inhibit production of GnRH possibly by blocking transcription of *GNRH1*, the gene coding for GnRH, or ii) inhibit production of LH by blocking transcription in the GnRH neurons of the gene, *LH1*, coding for LH.

C. **Construct two alternative explanations** of the role of

progesterone as a birth control drug. Your explanation can be in the form of descriptions or in terms of diagrams involving the key molecular components PG, PGR, LH, *LH1*, GEN, GnRH, and *GnRH1*.

An endocrine disruptor is a molecule with a structure that mimics a hormone and can interfere with regulation. The chemical bis-phenol A (BPA) has been used for many years in the production of plastics and is now widespread. BPA mimics estrogen. BPA is present in most humans at the concentration of 5 micrograms per kilogram of body weight. Whether or not that concentration is harmful is uncertain.

In a study of  $\text{Ca}^{+2}$  oscillations in GnRH expressing neurons, Klenke and co-workers (*Endocrinology*, 157, 2016) presented evidence that BPA switches off oscillations even at these very low concentrations. This suggests a mechanism for the results from an earlier investigation in which female rats were fed low and high levels of estrogen (EE) and BPA during pregnancy. Measurements were made of the levels of expression of an estrogen nuclear receptor in the hypothalamus of the pups just after birth (Cao et al., *Toxicological Sciences*, 133, 2013). Their data are shown in the graph below.

**Figure 28.22**

Using the data, the graph at the top compares expression in a “do-nothing” control (Naïve) and a control (Vehicle) in which a feeding tube is used to deliver nutrients during pregnancy. The graph at the bottom shows expression levels in pups born to female rats with four different treatments of estrogen (EE) and bis-phenol A (BPA).

D. Compared to the naïve control where homeostasis is not disrupted, qualitatively **analyze** these data for the disruption of the endocrine system in offspring of a female rat exposed to both physical and chemical stresses.

E. In female sheep, the estrus cycle is coordinated by the length of the day and does not begin until day length shortens. The gestation period of sheep is roughly 150 days.

- **Predict** the effect on fitness of this control of gene

expression by an external stimulus.

- The “ram effect” is a livestock management practice in Australia to induce ovulation by exposing an anestrus (when the estrus cycle is inactive) ewe to a ram. Compare this phenomenon with the results of delivering nutrients and hormones using a feeding tube to **construct** a possible **explanation** for the ram effect.

# 29 | THE MUSCULOSKELETAL SYSTEM

**Figure 29.1** Improvements in the design of prostheses have allowed for a wider range of activities in recipients. (credit: modification of work by Stuart Grout)

## Chapter Outline

- 29.1: Types of Skeletal Systems**
- 29.2: Bone**
- 29.3: Joints and Skeletal Movement**
- 29.4: Muscle Contraction and Locomotion**

## Introduction

The muscular and skeletal systems provide support to the body and allow for a wide range of movement. The bones of the skeletal system protect the body's internal organs and support the weight of the body. The muscles of the muscular system contract and pull on the bones, allowing for movements as diverse as standing, walking, running, and grasping items.

Injury or disease affecting the musculoskeletal system can be very debilitating. In humans, the most common musculoskeletal diseases worldwide are caused by malnutrition. Ailments that affect the joints are also widespread, such as arthritis, which can make movement difficult and—in advanced cases—completely impair mobility. In severe cases in which the joint has suffered extensive damage, joint replacement surgery may be needed.

Progress in the science of prosthesis design has resulted in the development of artificial joints, with joint replacement surgery in the hips and knees being the most common. Replacement joints for shoulders, elbows, and fingers are also available. Even with this progress, there is still room for improvement in the design of prostheses. The state-of-the-art

prostheses have limited durability and therefore wear out quickly, particularly in young or active individuals.

The field of robotic prosthesis focuses on prosthetics that are attached directly to the skeleton and can be controlled by the mind by using implanted neuromuscular interfaces. You can read more about this exciting research at the **Science Daily website (<http://openstaxcollege.org/l/32prosthesis>)**.

## 29.1 | Types of Skeletal Systems

In this section, you will explore the following questions:

- What are the characteristics of the different types of animal skeletal systems?
- What are the roles of the various components of the human skeletal system?

### Connection for AP® Courses

Much of the information in this section is not in scope for AP®. However, as a student of biology you should have a fundamental understanding of how the muscular and skeletal systems work together to provide support and protection while allowing for a range of movement. Bones provide a storage area for calcium and phosphorus salts and also are the site of blood cell formation. In a later section, knowledge of the nervous system will be used to understand the musculoskeletal system because muscle contraction depends on neural input. Events occurring at the neuromuscular junction are similar to events occurring at synapses between neurons as discussed in the chapter on the nervous system. Humans, and most animals depend on movement for daily activities. From an evolutionary perspective, the transition of animals onto land required changes in body design as locomotion on land presented a number of new challenges for animals that were adapted to movement in the water, such as the effect of gravity and lack of buoyancy. Literally step-by-step, these adaptations accumulated. Exploring the evolution of the musculoskeletal system in animals would provide information on this history.

Information presented and examples highlighted in this section are not within the scope for AP® and do not align to the Curriculum Framework.

### Hydrostatic Skeleton

A **hydrostatic skeleton** is a skeleton formed by a fluid-filled compartment within the body, called the coelom. The organs of the coelom are supported by the aqueous fluid, which also resists external compression. This compartment is under hydrostatic pressure because of the fluid and supports the other organs of the organism. This type of skeletal system is found in soft-bodied animals such as sea anemones, earthworms, Cnidaria, and other invertebrates (Figure 29.2).

**Figure 29.2** The skeleton of the red-knobbed sea star (*Protoreaster linckii*) is an example of a hydrostatic skeleton. (credit: "Amada44"/Wikimedia Commons)

Movement in a hydrostatic skeleton is provided by muscles that surround the coelom. The muscles in a hydrostatic skeleton contract to change the shape of the coelom; the pressure of the fluid in the coelom produces movement. For example, earthworms move by waves of muscular contractions of the skeletal muscle of the body wall hydrostatic skeleton, called peristalsis, which alternately shorten and lengthen the body. Lengthening the body extends the anterior end of the organism. Most organisms have a mechanism to fix themselves in the substrate. Shortening the muscles then draws the posterior portion of the body forward. Although a hydrostatic skeleton is well-suited to invertebrate organisms such as earthworms

and some aquatic organisms, it is not an efficient skeleton for terrestrial animals.

## Exoskeleton

An **exoskeleton** is an external skeleton that consists of a hard encasement on the surface of an organism. For example, the shells of crabs and insects are exoskeletons (Figure 29.3). This skeleton type provides defence against predators, supports the body, and allows for movement through the contraction of attached muscles. As with vertebrates, muscles must cross a joint inside the exoskeleton. Shortening of the muscle changes the relationship of the two segments of the exoskeleton. Arthropods such as crabs and lobsters have exoskeletons that consist of 30–50 percent chitin, a polysaccharide derivative of glucose that is a strong but flexible material. Chitin is secreted by the epidermal cells. The exoskeleton is further strengthened by the addition of calcium carbonate in organisms such as the lobster. Because the exoskeleton is acellular, arthropods must periodically shed their exoskeletons because the exoskeleton does not grow as the organism grows.

**Figure 29.3** Muscles attached to the exoskeleton of the Halloween crab (*Gecarcinus quadratus*) allow it to move.

## Endoskeleton

An **endoskeleton** is a skeleton that consists of hard, mineralized structures located within the soft tissue of organisms. An example of a primitive endoskeletal structure is the spicules of sponges. The bones of vertebrates are composed of tissues, whereas sponges have no true tissues (Figure 29.4). Endoskeletons provide support for the body, protect internal organs, and allow for movement through contraction of muscles attached to the skeleton.

**Figure 29.4** The skeletons of humans and horses are examples of endoskeletons. (credit: Ross Murphy)

The human skeleton is an endoskeleton that consists of 206 bones in the adult. It has five main functions: providing support to the body, storing minerals and lipids, producing blood cells, protecting internal organs, and allowing for movement. The skeletal system in vertebrates is divided into the axial skeleton (which consists of the skull, vertebral column, and rib cage), and the appendicular skeleton (which consists of the shoulders, limb bones, the pectoral girdle, and the pelvic girdle).

Visit the **interactive body** ([http://openstaxcollege.org/l/virt\\_skeleton](http://openstaxcollege.org/l/virt_skeleton)) site to build a virtual skeleton: select "skeleton" and click through the activity to place each bone.

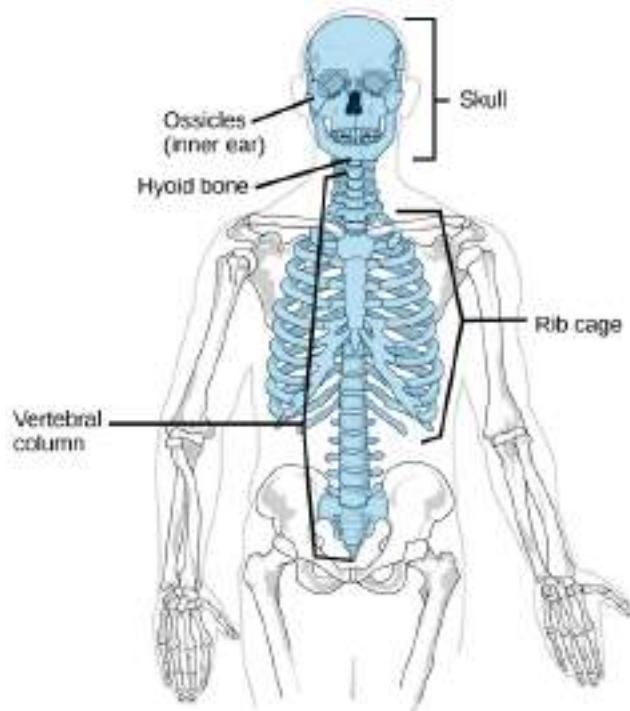

List at least three bones that you positioned in the virtual body (**in this simulation** ([http://www.bbc.co.uk/science/humanbody/body/interactives/3djigsaw\\_02/index.shtml?skeleton](http://www.bbc.co.uk/science/humanbody/body/interactives/3djigsaw_02/index.shtml?skeleton))).

- a. ribs, fibula, sacrum
- b. fibula, patella, sternum
- c. gliding joint, sacrum, sternum
- d. ribs, mandible, fibula

## Human Axial Skeleton

The **axial skeleton** forms the central axis of the body and includes the bones of the skull, ossicles of the middle ear, hyoid bone of the throat, vertebral column, and the thoracic cage (ribcage) (**Figure 29.5**). The function of the axial skeleton is to provide support and protection for the brain, the spinal cord, and the organs in the ventral body cavity. It provides a surface

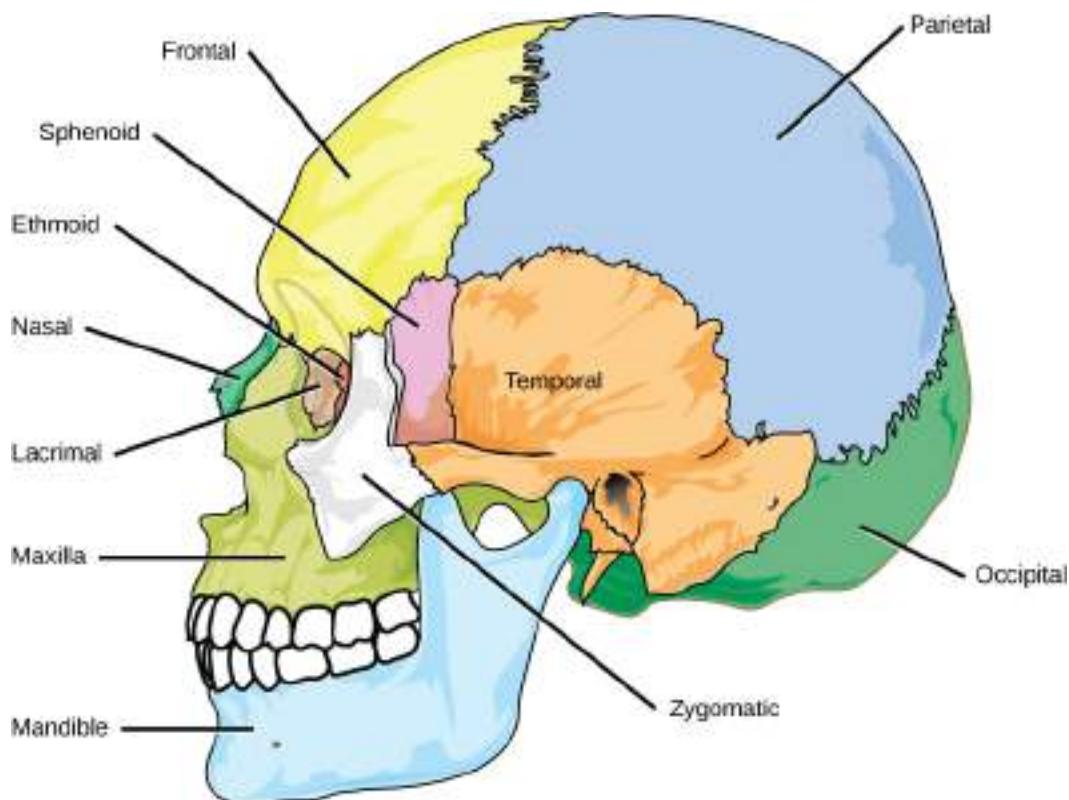

for the attachment of muscles that move the head, neck, and trunk, performs respiratory movements, and stabilizes parts of the appendicular skeleton.

**Figure 29.5** The axial skeleton consists of the bones of the skull, ossicles of the middle ear, hyoid bone, vertebral column, and rib cage. (credit: modification of work by Mariana Ruiz Villareal)

### The Skull

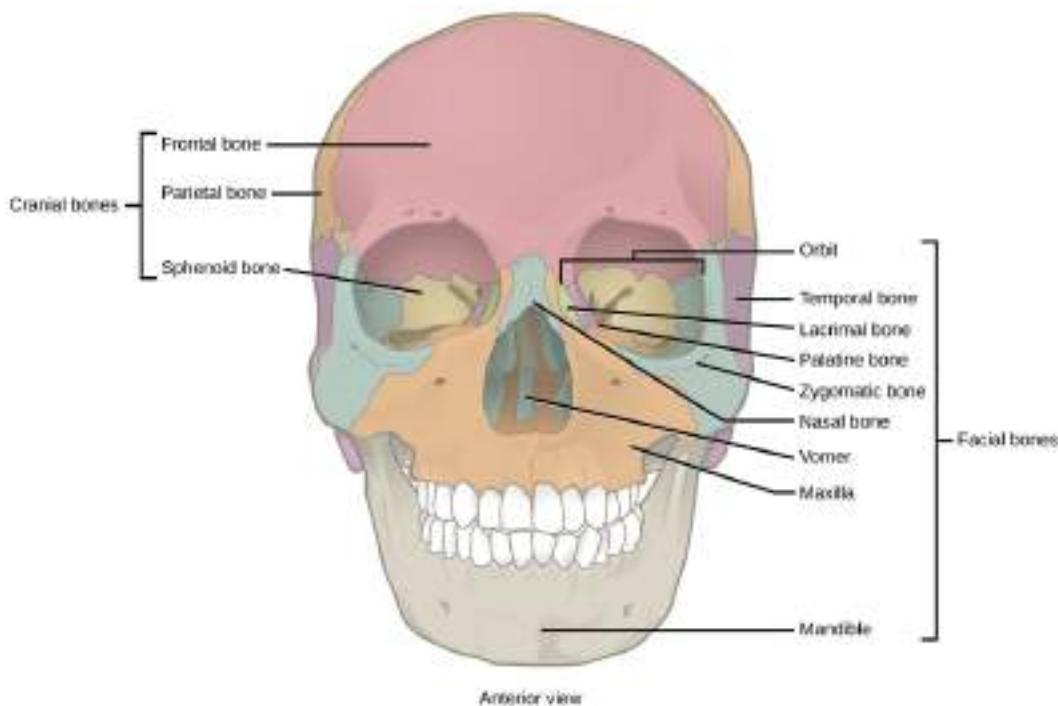

The bones of the **skull** support the structures of the face and protect the brain. The skull consists of 22 bones, which are divided into two categories: cranial bones and facial bones. The **cranial bones** are eight bones that form the cranial cavity, which encloses the brain and serves as an attachment site for the muscles of the head and neck. The eight cranial bones are the frontal bone, two parietal bones, two temporal bones, occipital bone, sphenoid bone, and the ethmoid bone. Although the bones developed separately in the embryo and fetus, in the adult, they are tightly fused with connective tissue and adjoining bones do not move (**Figure 29.6**).

**Figure 29.6** The bones of the skull support the structures of the face and protect the brain. (credit: modification of work by Mariana Ruiz Villareal)

The **auditory ossicles** of the middle ear transmit sounds from the air as vibrations to the fluid-filled cochlea. The auditory ossicles consist of three bones each: the malleus, incus, and stapes. These are the smallest bones in the body and are unique to mammals.

Fourteen **facial bones** form the face, provide cavities for the sense organs (eyes, mouth, and nose), protect the entrances to the digestive and respiratory tracts, and serve as attachment points for facial muscles. The 14 facial bones are the nasal bones, the maxillary bones, zygomatic bones, palatine, vomer, lacrimal bones, the inferior nasal conchae, and the mandible. All of these bones occur in pairs except for the mandible and the vomer (**Figure 29.7**).

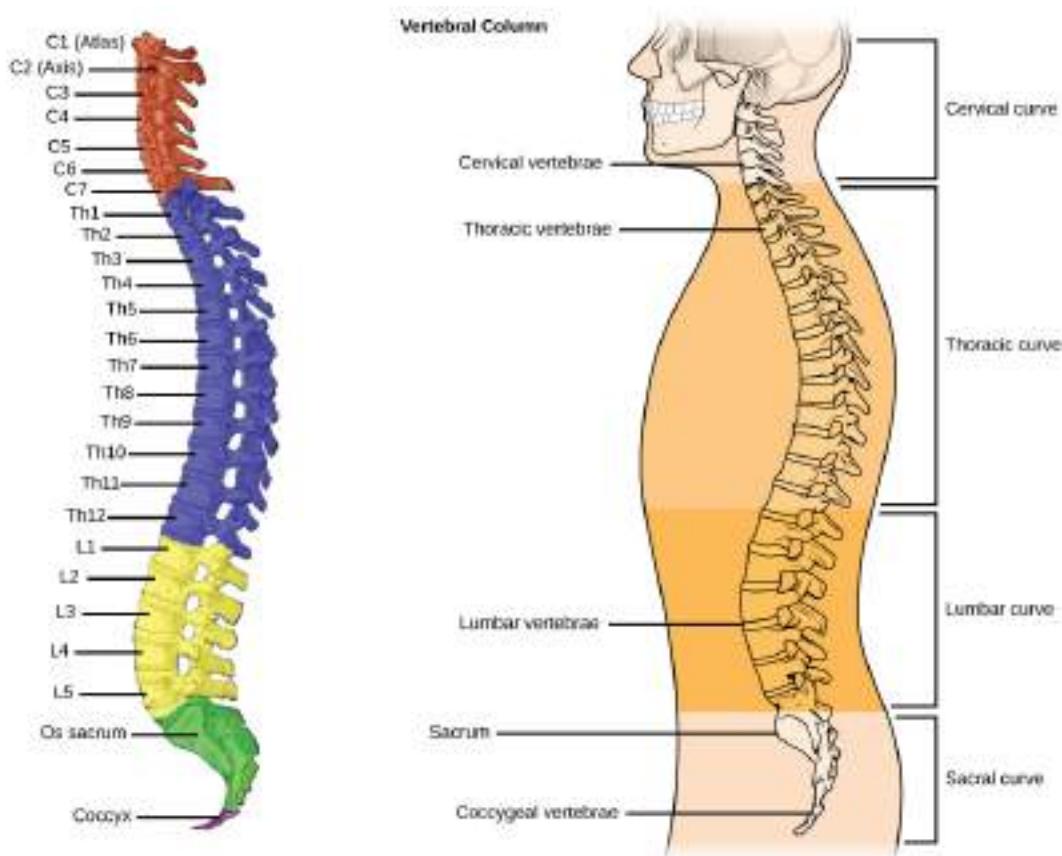

**Figure 29.7** The cranial bones, including the frontal, parietal, and sphenoid bones, cover the top of the head. The facial bones of the skull form the face and provide cavities for the eyes, nose, and mouth.

Although it is not found in the skull, the hyoid bone is considered a component of the axial skeleton. The **hyoid bone** lies below the mandible in the front of the neck. It acts as a movable base for the tongue and is connected to muscles of the jaw, larynx, and tongue. The mandible articulates with the base of the skull. The mandible controls the opening to the airway and gut. In animals with teeth, the mandible brings the surfaces of the teeth in contact with the maxillary teeth.

#### **The Vertebral Column**

The **vertebral column**, or spinal column, surrounds and protects the spinal cord, supports the head, and acts as an attachment point for the ribs and muscles of the back and neck. The adult vertebral column comprises 26 bones: the 24 vertebrae, the sacrum, and the coccyx bones. In the adult, the sacrum is typically composed of five vertebrae that fuse into one. The coccyx is typically 3–4 vertebrae that fuse into one. Around the age of 70, the sacrum and the coccyx may fuse together. We begin life with approximately 33 vertebrae, but as we grow, several vertebrae fuse together. The adult vertebrae are further divided into the 7 cervical vertebrae, 12 thoracic vertebrae, and 5 lumbar vertebrae (**Figure 29.8**).

**Figure 29.8** (a) The vertebral column consists of seven cervical vertebrae (C1–7) twelve thoracic vertebrae (Th1–12), five lumbar vertebrae (L1–5), the os sacrum, and the coccyx. (b) Spinal curves increase the strength and flexibility of the spine. (credit a: modification of work by Uwe Gille based on original work by Gray's Anatomy; credit b: modification of work by NCI, NIH)

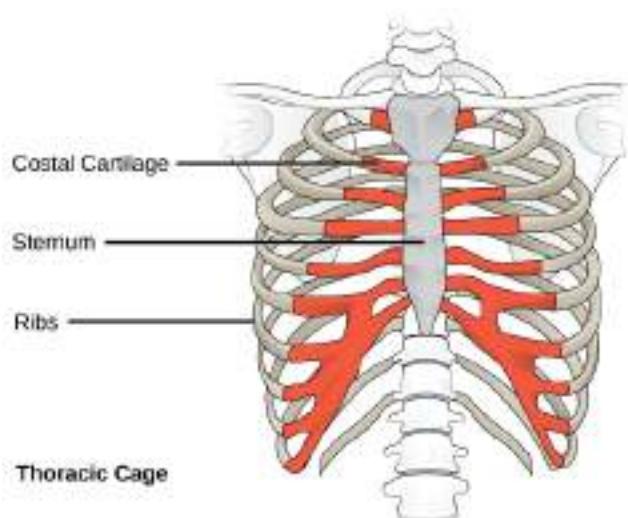

Each vertebral body has a large hole in the center through which the nerves of the spinal cord pass. There is also a notch on each side through which the spinal nerves, which serve the body at that level, can exit from the spinal cord. The vertebral column is approximately 71 cm (28 inches) in adult male humans and is curved, which can be seen from a side view. The names of the spinal curves correspond to the region of the spine in which they occur. The thoracic and sacral curves are concave (curve inwards relative to the front of the body) and the cervical and lumbar curves are convex (curve outwards relative to the front of the body). The arched curvature of the vertebral column increases its strength and flexibility, allowing it to absorb shocks like a spring (**Figure 29.8**).

**Intervertebral discs** composed of fibrous cartilage lie between adjacent vertebral bodies from the second cervical vertebra to the sacrum. Each disc is part of a joint that allows for some movement of the spine and acts as a cushion to absorb shocks from movements such as walking and running. Intervertebral discs also act as ligaments to bind vertebrae together. The inner part of discs, the nucleus pulposus, hardens as people age and becomes less elastic. This loss of elasticity diminishes its ability to absorb shocks.

### The Thoracic Cage

The **thoracic cage**, also known as the ribcage, is the skeleton of the chest, and consists of the ribs, sternum, thoracic vertebrae, and costal cartilages (**Figure 29.9**). The thoracic cage encloses and protects the organs of the thoracic cavity, including the heart and lungs. It also provides support for the shoulder girdles and upper limbs, and serves as the attachment point for the diaphragm, muscles of the back, chest, neck, and shoulders. Changes in the volume of the thorax enable breathing.

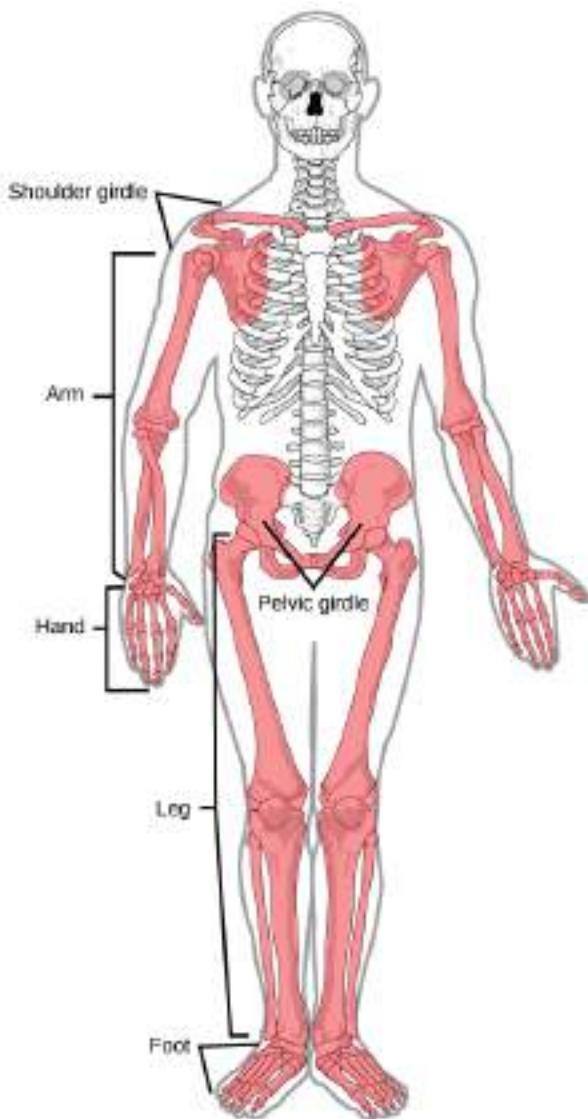

The **sternum**, or breastbone, is a long, flat bone located at the anterior of the chest. It is formed from three bones that fuse in the adult. The **ribs** are 12 pairs of long, curved bones that attach to the thoracic vertebrae and curve toward the front of the body, forming the ribcage. Costal cartilages connect the anterior ends of the ribs to the sternum, with the exception of rib pairs 11 and 12, which are free-floating ribs.

**Figure 29.9** The thoracic cage, or rib cage, protects the heart and the lungs. (credit: modification of work by NCI, NIH)

## Human Appendicular Skeleton

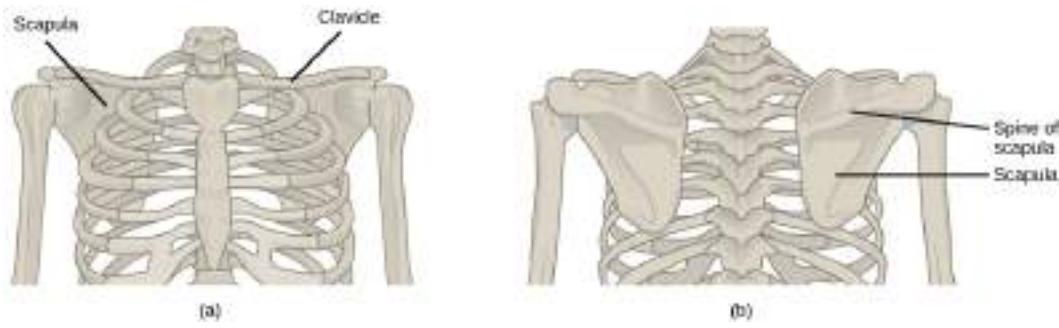

The **appendicular skeleton** is composed of the bones of the upper limbs (which function to grasp and manipulate objects) and the lower limbs (which permit locomotion). It also includes the pectoral girdle, or shoulder girdle, that attaches the upper limbs to the body, and the pelvic girdle that attaches the lower limbs to the body (**Figure 29.10**).

**Figure 29.10** The appendicular skeleton is composed of the bones of the pectoral limbs (arm, forearm, hand), the pelvic limbs (thigh, leg, foot), the pectoral girdle, and the pelvic girdle. (credit: modification of work by Mariana Ruiz Villareal)

#### The Pectoral Girdle

The **pectoral girdle** bones provide the points of attachment of the upper limbs to the axial skeleton. The human pectoral girdle consists of the clavicle (or collarbone) in the anterior, and the scapula (or shoulder blades) in the posterior (**Figure 29.11**).

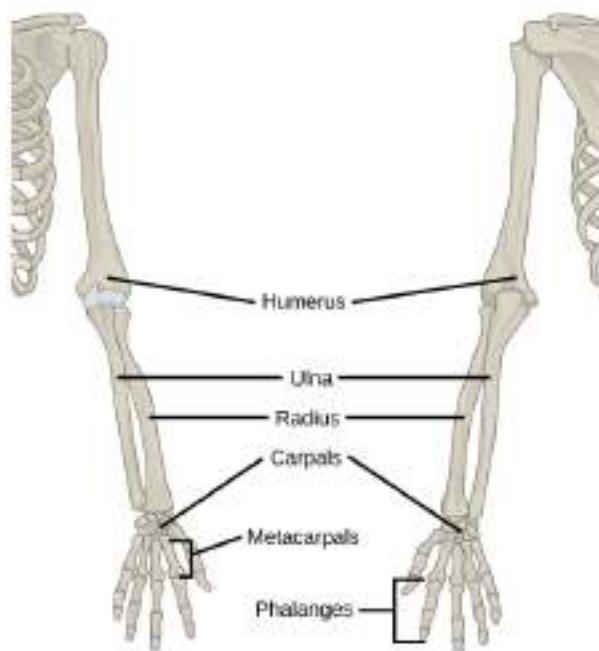

**Figure 29.11** (a) The pectoral girdle in primates consists of the clavicles and scapulae. (b) The posterior view reveals the spine of the scapula to which muscle attaches.

The **clavicles** are S-shaped bones that position the arms on the body. The clavicles lie horizontally across the front of the thorax (chest) just above the first rib. These bones are fairly fragile and are susceptible to fractures. For example, a fall with the arms outstretched causes the force to be transmitted to the clavicles, which can break if the force is excessive. The clavicle articulates with the sternum and the scapula.

The **scapulae** are flat, triangular bones that are located at the back of the pectoral girdle. They support the muscles crossing the shoulder joint. A ridge, called the spine, runs across the back of the scapula and can easily be felt through the skin ([Figure 29.11](#)). The spine of the scapula is a good example of a bony protrusion that facilitates a broad area of attachment for muscles to bone.

### **The Upper Limb**

The upper limb contains 30 bones in three regions: the arm (shoulder to elbow), the forearm (ulna and radius), and the wrist and hand ([Figure 29.12](#)).

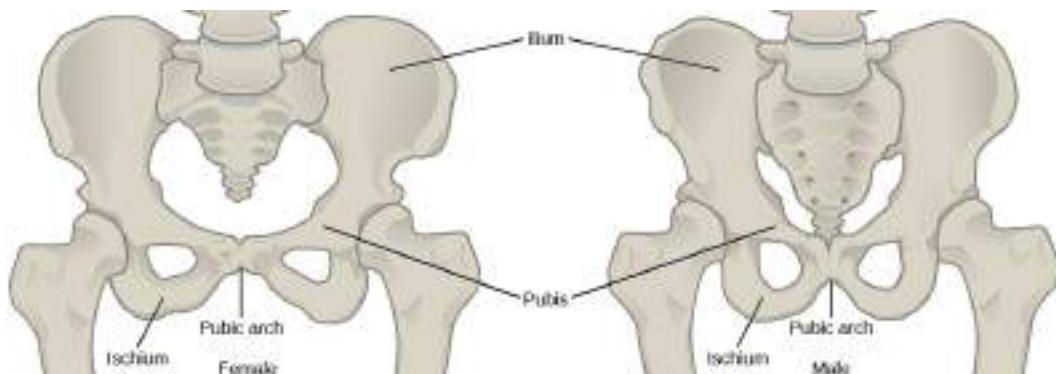

**Figure 29.12** The upper limb consists of the humerus of the upper arm, the radius and ulna of the forearm, eight bones of the carpus, five bones of the metacarpus, and 14 bones of the phalanges.

An **articulation** is any place at which two bones are joined. The **humerus** is the largest and longest bone of the upper limb and the only bone of the arm. It articulates with the scapula at the shoulder and with the forearm at the elbow. The **forearm** extends from the elbow to the wrist and consists of two bones: the ulna and the radius. The **radius** is located along the lateral (thumb) side of the forearm and articulates with the humerus at the elbow. The **ulna** is located on the medial aspect (pinky-finger side) of the forearm. It is longer than the radius. The ulna articulates with the humerus at the elbow. The radius and ulna also articulate with the carpal bones and with each other, which in vertebrates enables a variable degree of rotation of the carpus with respect to the long axis of the limb. The hand includes the eight bones of the **carpus** (wrist), the five bones of the **metacarpus** (palm), and the 14 bones of the **phalanges** (digits). Each digit consists of three phalanges, except for the thumb, when present, which has only two.

### **The Pelvic Girdle**

The **pelvic girdle** attaches to the lower limbs of the axial skeleton. Because it is responsible for bearing the weight of the body and for locomotion, the pelvic girdle is securely attached to the axial skeleton by strong ligaments. It also has deep sockets with robust ligaments to securely attach the femur to the body. The pelvic girdle is further strengthened by two large hip bones. In adults, the hip bones, or **coxal bones**, are formed by the fusion of three pairs of bones: the ilium, ischium, and pubis. The pelvis joins together in the anterior of the body at a joint called the pubic symphysis and with the bones of the sacrum at the posterior of the body.

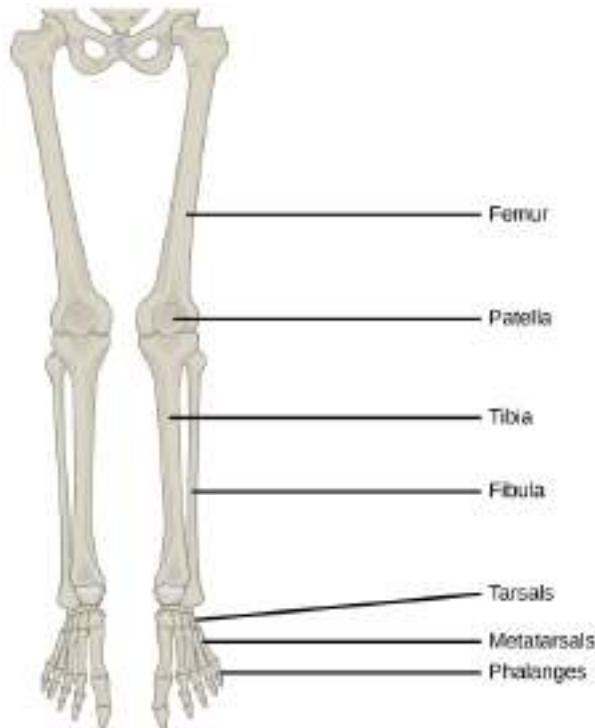

The female pelvis is slightly different from the male pelvis. Over generations of evolution, females with a wider pubic angle and larger diameter pelvic canal reproduced more successfully. Therefore, their offspring also had pelvic anatomy that enabled successful childbirth ([Figure 29.13](#)).

**Figure 29.13** To adapt to reproductive fitness, the (a) female pelvis is lighter, wider, shallower, and has a broader angle between the pubic bones than (b) the male pelvis.

### The Lower Limb

The **lower limb** consists of the thigh, the leg, and the foot. The bones of the lower limb are the femur (thigh bone), patella (kneecap), tibia and fibula (bones of the leg), tarsals (bones of the ankle), and metatarsals and phalanges (bones of the foot) (**Figure 29.14**). The bones of the lower limbs are thicker and stronger than the bones of the upper limbs because of the need to support the entire weight of the body and the resulting forces from locomotion. In addition to evolutionary fitness, the bones of an individual will respond to forces exerted upon them.

**Figure 29.14** The lower limb consists of the thigh (femur), kneecap (patella), leg (tibia and fibula), ankle (tarsals), and foot (metatarsals and phalanges) bones.

The **femur**, or thighbone, is the longest, heaviest, and strongest bone in the body. The femur and pelvis form the hip joint at the proximal end. At the distal end, the femur, tibia, and patella form the knee joint. The **patella**, or kneecap, is a triangular bone that lies anterior to the knee joint. The patella is embedded in the tendon of the femoral extensors (quadriceps). It improves knee extension by reducing friction. The **tibia**, or shinbone, is a large bone of the leg that is located directly below the knee. The tibia articulates with the femur at its proximal end, with the fibula and the tarsal bones at its distal end. It is the second largest bone in the human body and is responsible for transmitting the weight of the body from the femur to the foot. The **fibula**, or calf bone, parallels and articulates with the tibia. It does not articulate with the femur and does not bear weight. The fibula acts as a site for muscle attachment and forms the lateral part of the ankle joint.

The **tarsals** are the seven bones of the ankle. The ankle transmits the weight of the body from the tibia and the fibula to the

foot. The **metatarsals** are the five bones of the foot. The phalanges are the 14 bones of the toes. Each toe consists of three phalanges, except for the big toe that has only two (Figure 29.15). Variations exist in other species; for example, the horse's metacarpals and metatarsals are oriented vertically and do not make contact with the substrate.

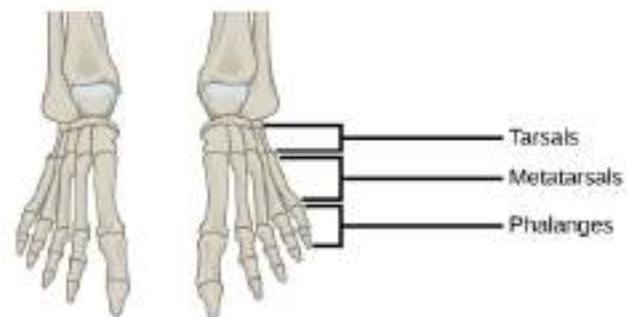

Figure 29.15 This drawing shows the bones of the human foot and ankle, including the metatarsals and the phalanges.

## evolution CONNECTION

### Evolution of Body Design for Locomotion on Land

The transition of vertebrates onto land required a number of changes in body design, as movement on land presents a number of challenges for animals that are adapted to movement in water. The buoyancy of water provides a certain amount of lift, and a common form of movement by fish is lateral undulations of the entire body. This back and forth movement pushes the body against the water, creating forward movement. In most fish, the muscles of paired fins attach to girdles within the body, allowing for some control of locomotion. As certain fish began moving onto land, they retained their lateral undulation form of locomotion (anguilliform). However, instead of pushing against water, their fins or flippers became points of contact with the ground, around which they rotated their bodies.

The effect of gravity and the lack of buoyancy on land meant that body weight was suspended on the limbs, leading to increased strengthening and ossification of the limbs. The effect of gravity also required changes to the axial skeleton. Lateral undulations of land animal vertebral columns cause torsional strain. A firmer, more ossified vertebral column became common in terrestrial tetrapods because it reduces strain while providing the strength needed to support the body's weight. In later tetrapods, the vertebrae began allowing for vertical motion rather than lateral flexion. Another change in the axial skeleton was the loss of a direct attachment between the pectoral girdle and the head. This reduced the jarring to the head caused by the impact of the limbs on the ground. The vertebrae of the neck also evolved to allow movement of the head independently of the body.

The appendicular skeleton of land animals is also different from aquatic animals. The shoulders attach to the pectoral girdle through muscles and connective tissue, thus reducing the jarring of the skull. Because of a lateral undulating vertebral column, in early tetrapods, the limbs were splayed out to the side and movement occurred by performing "push-ups." The vertebrae of these animals had to move side-to-side in a similar manner to fish and reptiles. This type of motion requires large muscles to move the limbs toward the midline; it was almost like walking while doing push-ups, and it is not an efficient use of energy. Later tetrapods have their limbs placed under their bodies, so that each stride requires less force to move forward. This resulted in decreased adductor muscle size and an increased range of motion of the scapulae. This also restricts movement primarily to one plane, creating forward motion rather than moving the limbs upward as well as forward. The femur and humerus were also rotated, so that the ends of the limbs and digits were pointed forward, in the direction of motion, rather than out to the side. By placement underneath the body, limbs can swing forward like a pendulum to produce a stride that is more efficient for moving over land.

Which of the following changes evolved in the animal skeletal system as animals moved from water to land?

- a. decreased ossification of bones
- b. increased attachment between pectoral girdle and head
- c. rotation of femur and humerus to point to the side
- d. placement of limbs under the body

## 29.2 | Bone

In this section, you will explore the following questions:

- What are examples of the different types of bones and their functions in the human skeleton?
- What are the roles of the different cell types and tissue types in bone?
- How do bones develop, grow, and undergo remodeling and repair?

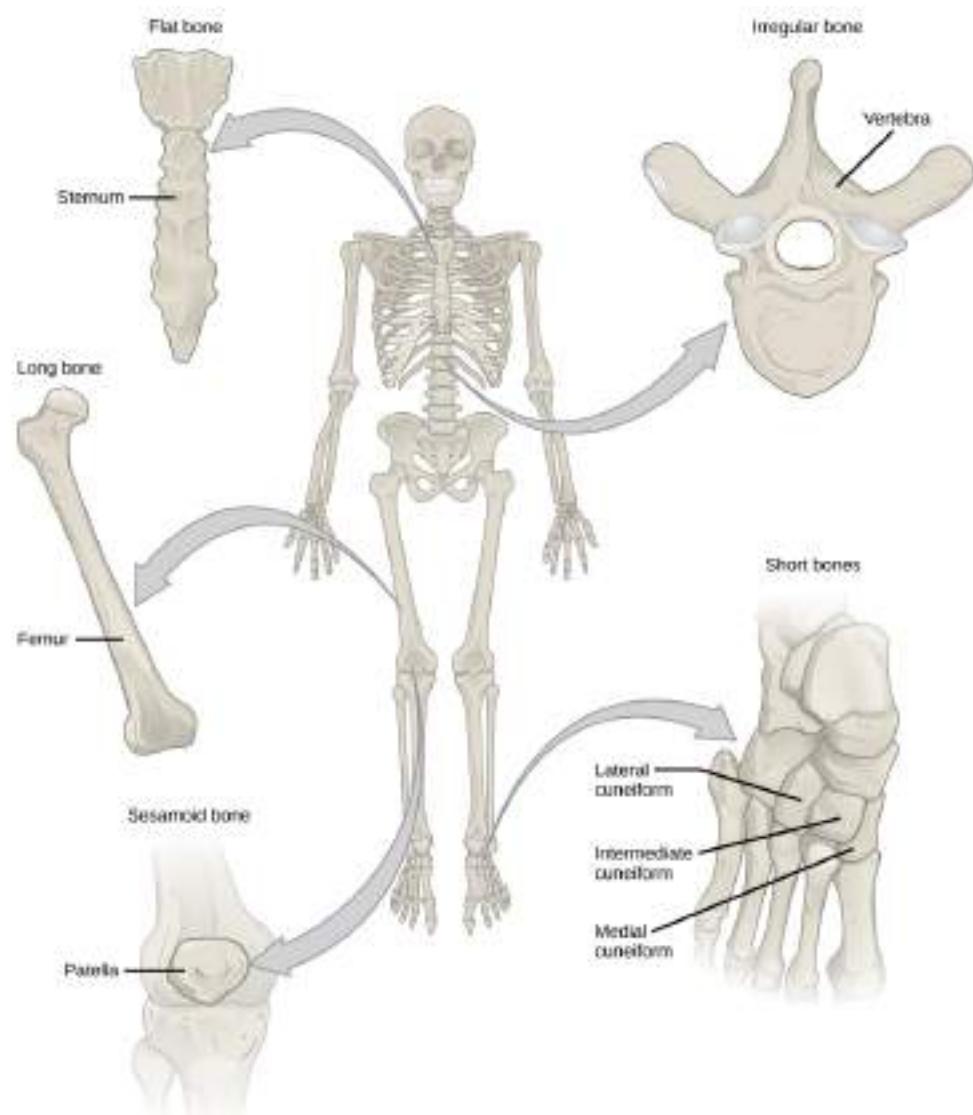

### Connection for AP<sup>®</sup> Courses

The information in this section is not within the scope for AP<sup>®</sup> and does not align with the curriculum framework. However, as a student of biology it is important to understand the types of bones and bone tissues as well as their functions because this basic part of anatomy is an excellent example of form follows function. For example, spongy bone tissue is found in the inner layer of bones and contains blood vessels to deliver nutrients and remove waste from bone cells.

**Bone, or osseous tissue,** is a connective tissue that constitutes the endoskeleton. It contains specialized cells and a matrix of mineral salts and collagen fibers.

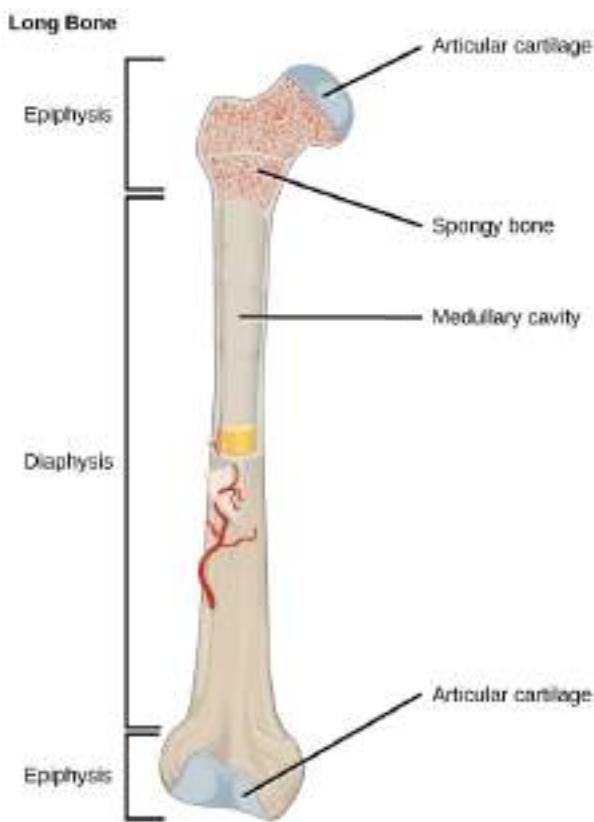

The mineral salts primarily include hydroxyapatite, a mineral formed from calcium phosphate. **Calcification** is the process of deposition of mineral salts on the collagen fiber matrix that crystallizes and hardens the tissue. The process of calcification only occurs in the presence of collagen fibers.

The bones of the human skeleton are classified by their shape: long bones, short bones, flat bones, sutural bones, sesamoid bones, and irregular bones ([Figure 29.16](#)).

**Figure 29.16** Shown are different types of bones: flat, irregular, long, short, and sesamoid.

**Long bones** are longer than they are wide and have a shaft and two ends. The **diaphysis**, or central shaft, contains bone marrow in a marrow cavity. The rounded ends, the **epiphyses**, are covered with articular cartilage and are filled with red bone marrow, which produces blood cells (Figure 29.17). Most of the limb bones are long bones—for example, the femur, tibia, ulna, and radius. Exceptions to this include the patella and the bones of the wrist and ankle.

**Figure 29.17** The long bone is covered by articular cartilage at either end and contains bone marrow (shown in yellow in this illustration) in the marrow cavity.

**Short bones**, or cuboidal bones, are bones that are the same width and length, giving them a cube-like shape. For example, the bones of the wrist (carpal) and ankle (tarsal) are short bones ([Figure 29.16](#)).

**Flat bones** are thin and relatively broad bones that are found where extensive protection of organs is required or where broad surfaces of muscle attachment are required. Examples of flat bones are the sternum (breast bone), ribs, scapulae (shoulder blades), and the roof of the skull ([Figure 29.16](#)).

**Irregular bones** are bones with complex shapes. These bones may have short, flat, notched, or ridged surfaces. Examples of irregular bones are the vertebrae, hip bones, and several skull bones.

**Sesamoid bones** are small, flat bones and are shaped similarly to a sesame seed. The patellae are sesamoid bones ([Figure 29.18](#)). Sesamoid bones develop inside tendons and may be found near joints at the knees, hands, and feet.

**Figure 29.18** The patella of the knee is an example of a sesamoid bone.

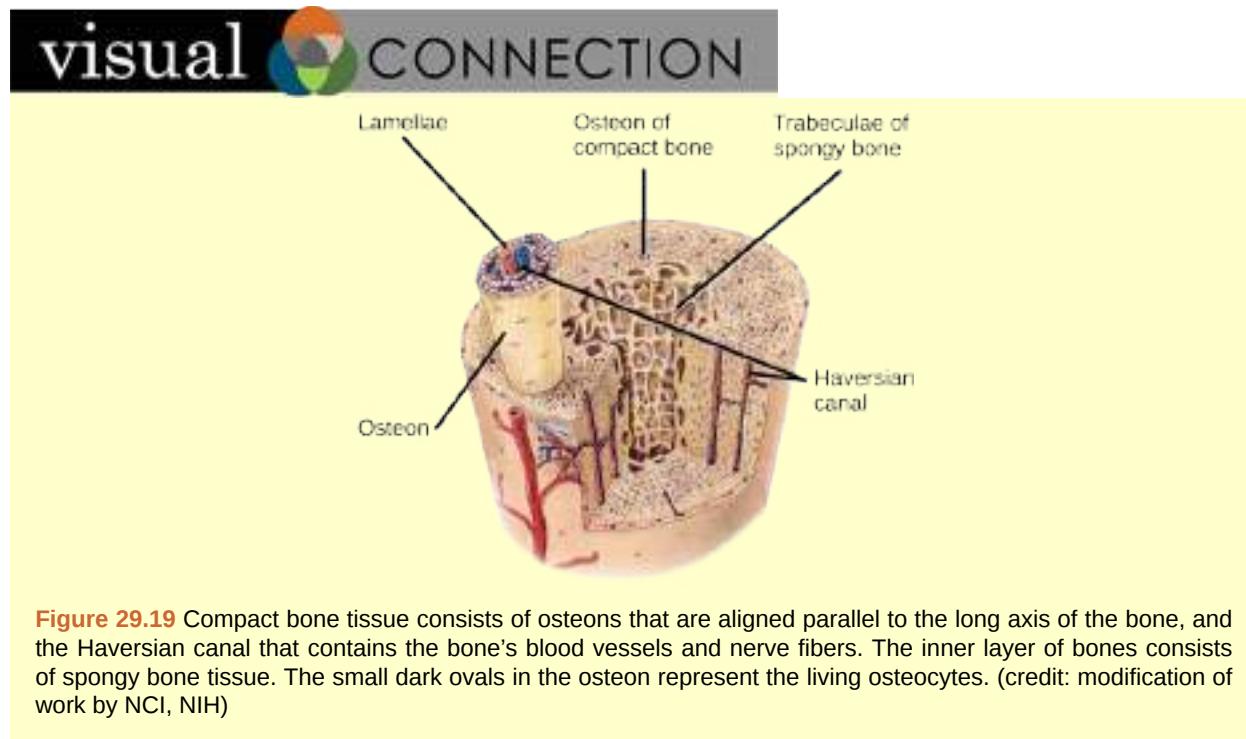

**Sutural bones** are small, flat, irregularly shaped bones. They may be found between the flat bones of the skull. They vary in number, shape, size, and position.

## Bone Tissue

Bones are considered organs because they contain various types of tissue, such as blood, connective tissue, nerves, and bone tissue. Osteocytes, the living cells of bone tissue, form the mineral matrix of bones. There are two types of bone tissue: compact and spongy.

### **Compact Bone Tissue**

**Compact bone** (or cortical bone) forms the hard external layer of all bones and surrounds the medullary cavity, or bone marrow. It provides protection and strength to bones. Compact bone tissue consists of units called osteons or Haversian systems. **Osteons** are cylindrical structures that contain a mineral matrix and living osteocytes connected by canaliculi, which transport blood. They are aligned parallel to the long axis of the bone. Each osteon consists of **lamellae**, which are layers of compact matrix that surround a central canal called the Haversian canal. The **Haversian canal** (osteonic canal) contains the bone's blood vessels and nerve fibers (**Figure 29.19**). Osteons in compact bone tissue are aligned in the same direction along lines of stress and help the bone resist bending or fracturing. Therefore, compact bone tissue is prominent in areas of bone at which stresses are applied in only a few directions.

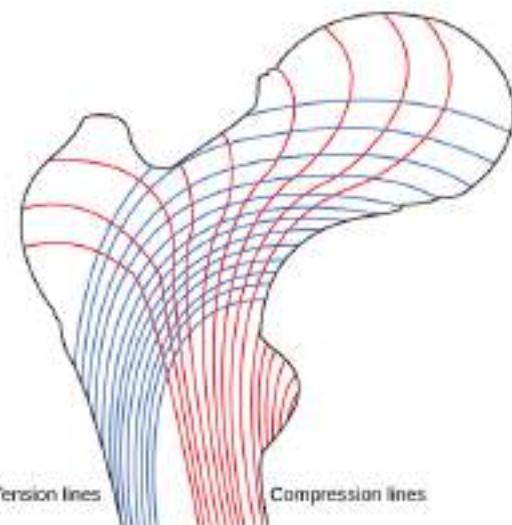

### Spongy Bone Tissue

Whereas compact bone tissue forms the outer layer of all bones, **spongy bone** or cancellous bone forms the inner layer of all bones. Spongy bone tissue does not contain osteons that constitute compact bone tissue. Instead, it consists of **trabeculae**, which are lamellae that are arranged as rods or plates. Red bone marrow is found between the trabeculae. Blood vessels within this tissue deliver nutrients to osteocytes and remove waste. The red bone marrow of the femur and the interior of other large bones, such as the ileum, forms blood cells.

Spongy bone reduces the density of bone and allows the ends of long bones to compress as the result of stresses applied to the bone. Spongy bone is prominent in areas of bones that are not heavily stressed or where stresses arrive from many directions. The epiphyses of bones, such as the neck of the femur, are subject to stress from many directions. Imagine laying a heavy framed picture flat on the floor. You could hold up one side of the picture with a toothpick if the toothpick was perpendicular to the floor and the picture. Now drill a hole and stick the toothpick into the wall to hang up the picture. In this case, the function of the toothpick is to transmit the downward pressure of the picture to the wall. The force on the picture is straight down to the floor, but the force on the toothpick is both the picture wire pulling down and the bottom of the hole in the wall pushing up. The toothpick will break off right at the wall.

The neck of the femur is horizontal like the toothpick in the wall. The weight of the body pushes it down near the joint, but the vertical diaphysis of the femur pushes it up at the other end. The neck of the femur must be strong enough to transfer the downward force of the body weight horizontally to the vertical shaft of the femur (**Figure 29.20**).

**Figure 29.20** Trabeculae in spongy bone are arranged such that one side of the bone bears tension and the other withstands compression.

View **micrographs** ([http://openstaxcollege.org/l/muscle\\_tissue](http://openstaxcollege.org/l/muscle_tissue)) of musculoskeletal tissues as you review the anatomy.

Which type of connective tissue lacks collagen fibers?

- a. blood
- b. loose connective tissue
- c. cartilage
- d. bone

## Cell Types in Bones

Bone consists of four types of cells: osteoblasts, osteoclasts, osteocytes, and osteoprogenitor cells. **Osteoblasts** are bone cells that are responsible for bone formation. Osteoblasts synthesize and secrete the organic part and inorganic part of the extracellular matrix of bone tissue, and collagen fibers. Osteoblasts become trapped in these secretions and differentiate into less active osteocytes. **Osteoclasts** are large bone cells with up to 50 nuclei. They remove bone structure by releasing lysosomal enzymes and acids that dissolve the bony matrix. These minerals, released from bones into the blood, help regulate calcium concentrations in body fluids. Bone may also be resorbed for remodeling, if the applied stresses have changed. **Osteocytes** are mature bone cells and are the main cells in bony connective tissue; these cells cannot divide. Osteocytes maintain normal bone structure by recycling the mineral salts in the bony matrix. **Osteoprogenitor cells** are squamous stem cells that divide to produce daughter cells that differentiate into osteoblasts. Osteoprogenitor cells are important in the repair of fractures.

## Development of Bone

**Ossification**, or osteogenesis, is the process of bone formation by osteoblasts. Ossification is distinct from the process of calcification; whereas calcification takes place during the ossification of bones, it can also occur in other tissues. Ossification begins approximately six weeks after fertilization in an embryo. Before this time, the embryonic skeleton

consists entirely of fibrous membranes and hyaline cartilage. The development of bone from fibrous membranes is called intramembranous ossification; development from hyaline cartilage is called endochondral ossification. Bone growth continues until approximately age 25. Bones can grow in thickness throughout life, but after age 25, ossification functions primarily in bone remodeling and repair.

## Intramembranous Ossification

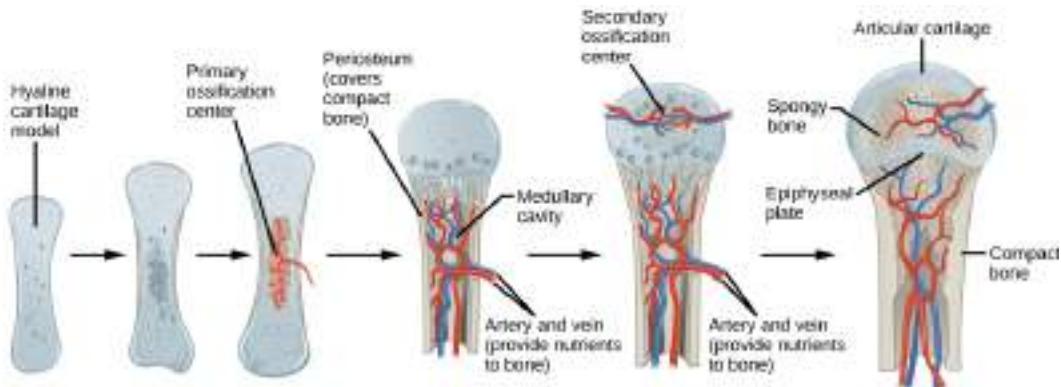

**Intramembranous ossification** is the process of bone development from fibrous membranes. It is involved in the formation of the flat bones of the skull, the mandible, and the clavicles. Ossification begins as mesenchymal cells form a template of the future bone. They then differentiate into osteoblasts at the ossification center. Osteoblasts secrete the extracellular matrix and deposit calcium, which hardens the matrix. The non-mineralized portion of the bone or osteoid continues to form around blood vessels, forming spongy bone. Connective tissue in the matrix differentiates into red bone marrow in the fetus. The spongy bone is remodeled into a thin layer of compact bone on the surface of the spongy bone.

### Endochondral Ossification

**Endochondral ossification** is the process of bone development from hyaline cartilage. All of the bones of the body, except for the flat bones of the skull, mandible, and clavicles, are formed through endochondral ossification.

In long bones, chondrocytes form a template of the hyaline cartilage diaphysis. Responding to complex developmental signals, the matrix begins to calcify. This calcification prevents diffusion of nutrients into the matrix, resulting in chondrocytes dying and the opening up of cavities in the diaphysis cartilage. Blood vessels invade the cavities, and osteoblasts and osteoclasts modify the calcified cartilage matrix into spongy bone. Osteoclasts then break down some of the spongy bone to create a marrow, or medullary, cavity in the center of the diaphysis. Dense, irregular connective tissue forms a sheath (periosteum) around the bones. The periosteum assists in attaching the bone to surrounding tissues, tendons, and ligaments. The bone continues to grow and elongate as the cartilage cells at the epiphyses divide.

In the last stage of prenatal bone development, the centers of the epiphyses begin to calcify. Secondary ossification centers form in the epiphyses as blood vessels and osteoblasts enter these areas and convert hyaline cartilage into spongy bone. Until adolescence, hyaline cartilage persists at the **epiphyseal plate** (growth plate), which is the region between the diaphysis and epiphysis that is responsible for the lengthwise growth of long bones (**Figure 29.21**).

**Figure 29.21** Endochondral ossification is the process of bone development from hyaline cartilage. The periosteum is the connective tissue on the outside of bone that acts as the interface between bone, blood vessels, tendons, and ligaments.

## Growth of Bone

Long bones continue to lengthen, potentially until adolescence, through the addition of bone tissue at the epiphyseal plate. They also increase in width through appositional growth.

### Lengthening of Long Bones

Chondrocytes on the epiphyseal side of the epiphyseal plate divide; one cell remains undifferentiated near the epiphysis, and one cell moves toward the diaphysis. The cells, which are pushed from the epiphysis, mature and are destroyed by calcification. This process replaces cartilage with bone on the diaphyseal side of the plate, resulting in a lengthening of the bone.

Long bones stop growing at around the age of 18 in females and the age of 21 in males in a process called epiphyseal plate closure. During this process, cartilage cells stop dividing and all of the cartilage is replaced by bone. The epiphyseal plate fades, leaving a structure called the epiphyseal line or epiphyseal remnant, and the epiphysis and diaphysis fuse.

### Thickening of Long Bones

**Appositional growth** is the increase in the diameter of bones by the addition of bony tissue at the surface of bones. Osteoblasts at the bone surface secrete bone matrix, and osteoclasts on the inner surface break down bone. The osteoblasts differentiate into osteocytes. A balance between these two processes allows the bone to thicken without becoming too heavy.

## Bone Remodeling and Repair

Bone renewal continues after birth into adulthood. **Bone remodeling** is the replacement of old bone tissue by new bone tissue. It involves the processes of bone deposition by osteoblasts and bone resorption by osteoclasts. Normal bone growth requires vitamins D, C, and A, plus minerals such as calcium, phosphorous, and magnesium. Hormones such as parathyroid hormone, growth hormone, and calcitonin are also required for proper bone growth and maintenance.

Bone turnover rates are quite high, with five to seven percent of bone mass being recycled every week. Differences in turnover rate exist in different areas of the skeleton and in different areas of a bone. For example, the bone in the head of the femur may be fully replaced every six months, whereas the bone along the shaft is altered much more slowly.

Bone remodeling allows bones to adapt to stresses by becoming thicker and stronger when subjected to stress. Bones that are not subject to normal stress, for example when a limb is in a cast, will begin to lose mass. A fractured or broken bone undergoes repair through four stages:

1. Blood vessels in the broken bone tear and hemorrhage, resulting in the formation of clotted blood, or a hematoma, at the site of the break. The severed blood vessels at the broken ends of the bone are sealed by the clotting process, and bone cells that are deprived of nutrients begin to die.
2. Within days of the fracture, capillaries grow into the hematoma, and phagocytic cells begin to clear away the dead cells. Though fragments of the blood clot may remain, fibroblasts and osteoblasts enter the area and begin to reform bone. Fibroblasts produce collagen fibers that connect the broken bone ends, and osteoblasts start to form spongy bone. The repair tissue between the broken bone ends is called the fibrocartilaginous callus, as it is composed of both hyaline and fibrocartilage (**Figure 29.22**). Some bone spicules may also appear at this point.
3. The fibrocartilaginous callus is converted into a bony callus of spongy bone. It takes about two months for the broken bone ends to be firmly joined together after the fracture. This is similar to the endochondral formation of bone, as cartilage becomes ossified; osteoblasts, osteoclasts, and bone matrix are present.
4. The bony callus is then remodelled by osteoclasts and osteoblasts, with excess material on the exterior of the bone and within the medullary cavity being removed. Compact bone is added to create bone tissue that is similar to the original, unbroken bone. This remodeling can take many months, and the bone may remain uneven for years.

**Figure 29.22** After this bone is set, a callus will knit the two ends together. (credit: Bill Rhodes)

## scientific method CONNECTION

### Decalcification of Bones

**Question:** What effect does the removal of calcium and collagen have on bone structure?

**Background:** Conduct a literature search on the role of calcium and collagen in maintaining bone structure. Conduct a literature search on diseases in which bone structure is compromised.

**Hypothesis:** Develop a hypothesis that states predictions of the flexibility, strength, and mass of bones that have had the calcium and collagen components removed. Develop a hypothesis regarding the attempt to add calcium back to decalcified bones.

**Test the hypothesis:** Test the prediction by removing calcium from chicken bones by placing them in a jar of vinegar for seven days. Test the hypothesis regarding adding calcium back to decalcified bone by placing the decalcified chicken bones into a jar of water with calcium supplements added. Test the prediction by denaturing the collagen from the bones by baking them at 250°C for three hours.

**Analyze the data:** Create a table showing the changes in bone flexibility, strength, and mass in the three different environments.

**Report the results:** Under which conditions was the bone most flexible? Under which conditions was the bone the strongest?

**Draw a conclusion:** Did the results support or refute the hypothesis? How do the results observed in this experiment correspond to diseases that destroy bone tissue?

## 29.3 | Joints and Skeletal Movement

In this section, you will explore the following questions:

- What are the different types of joints on the basis of structure?
- What is the role of joints in skeletal movement?

### Connection for AP<sup>®</sup> Courses

The information in this section is not within the scope for AP<sup>®</sup> and does not align with the curriculum framework. However, the material in this section is important to understanding how joints provide stability to the skeletal system. Furthermore, understanding the different types of joints will help one understand how the muscles are able to move bones in specific ways.

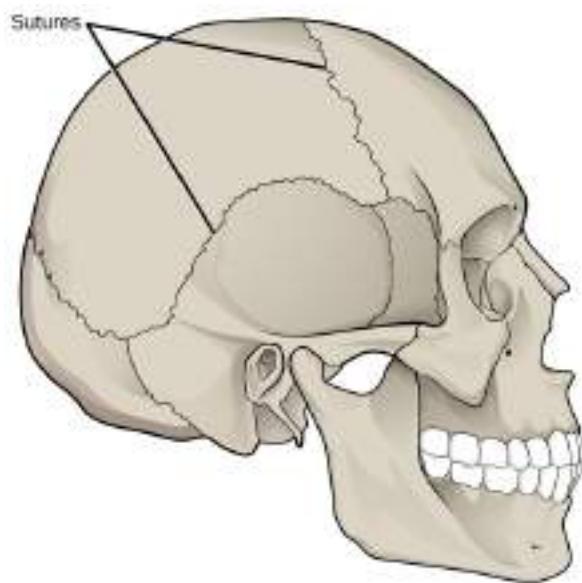

The point at which two or more bones meet is called a **joint**, or **articulation**. Joints are responsible for movement, such as the movement of limbs, and stability, such as the stability found in the bones of the skull.

### Classification of Joints on the Basis of Structure

There are two ways to classify joints: on the basis of their structure or on the basis of their function. The structural classification divides joints into bony, fibrous, cartilaginous, and synovial joints depending on the material composing the joint and the presence or absence of a cavity in the joint.

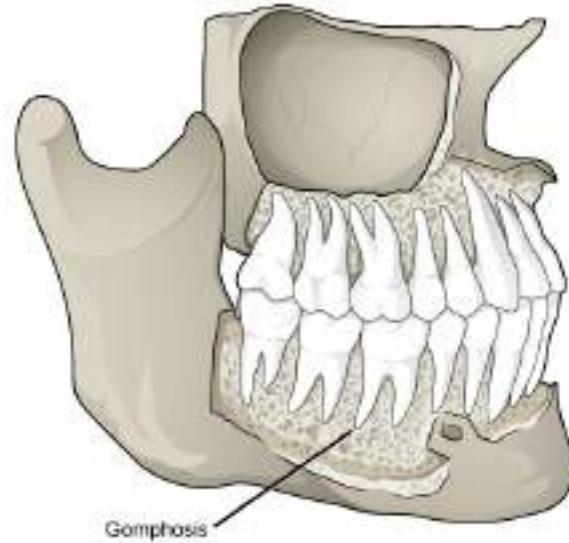

#### Fibrous Joints

The bones of **fibrous joints** are held together by fibrous connective tissue. There is no cavity, or space, present between the bones and so most fibrous joints do not move at all, or are only capable of minor movements. There are three types of fibrous joints: sutures, syndesmoses, and gomphoses. **Sutures** are found only in the skull and possess short fibers of connective tissue that hold the skull bones tightly in place (**Figure 29.23**).

**Figure 29.23** Sutures are fibrous joints found only in the skull.

**Syndesmoses** are joints in which the bones are connected by a band of connective tissue, allowing for more movement than in a suture. An example of a syndesmosis is the joint of the tibia and fibula in the ankle. The amount of movement in these types of joints is determined by the length of the connective tissue fibers. **Gomphoses** occur between teeth and their sockets; the term refers to the way the tooth fits into the socket like a peg (**Figure 29.24**). The tooth is connected to the socket by a connective tissue referred to as the periodontal ligament.

**Figure 29.24** Gomphoses are fibrous joints between the teeth and their sockets. (credit: modification of work by Gray's Anatomy)

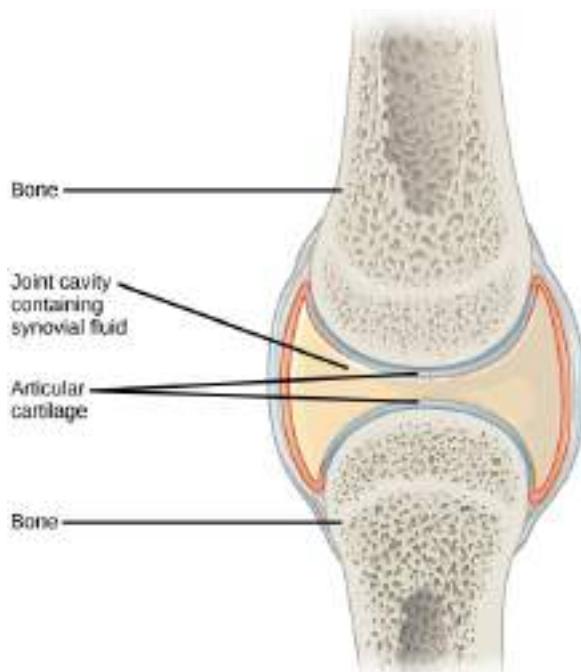

### Cartilaginous Joints

**Cartilaginous joints** are joints in which the bones are connected by cartilage. There are two types of cartilaginous joints: synchondroses and symphyses. In a **synchondrosis**, the bones are joined by hyaline cartilage. Synchondroses are found in the epiphyseal plates of growing bones in children. In **symphyses**, hyaline cartilage covers the end of the bone but the connection between bones occurs through fibrocartilage. Symphyses are found at the joints between vertebrae. Either type of cartilaginous joint allows for very little movement.

### Synovial Joints

**Synovial joints** are the only joints that have a space between the adjoining bones (**Figure 29.25**). This space is referred to as the synovial (or joint) cavity and is filled with synovial fluid. Synovial fluid lubricates the joint, reducing friction between the bones and allowing for greater movement. The ends of the bones are covered with articular cartilage, a hyaline cartilage,

and the entire joint is surrounded by an articular capsule composed of connective tissue that allows movement of the joint while resisting dislocation. Articular capsules may also possess ligaments that hold the bones together. Synovial joints are capable of the greatest movement of the three structural joint types; however, the more mobile a joint, the weaker the joint. Knees, elbows, and shoulders are examples of synovial joints.

**Figure 29.25** Synovial joints are the only joints that have a space or “synovial cavity” in the joint.

## Classification of Joints on the Basis of Function

The functional classification divides joints into three categories: synarthroses, amphiarthroses, and diarthroses. A **synarthrosis** is a joint that is immovable. This includes sutures, gomphoses, and synchondroses. **Amphiarthroses** are joints that allow slight movement, including syndesmoses and symphyses. **Diarthroses** are joints that allow for free movement of the joint, as in synovial joints.

### Movement at Synovial Joints

The wide range of movement allowed by synovial joints produces different types of movements. The movement of synovial joints can be classified as one of four different types: gliding, angular, rotational, or special movement.

#### **Gliding Movement**

**Gliding movements** occur as relatively flat bone surfaces move past each other. Gliding movements produce very little rotation or angular movement of the bones. The joints of the carpal and tarsal bones are examples of joints that produce gliding movements.

#### **Angular Movement**

**Angular movements** are produced when the angle between the bones of a joint changes. There are several different types of angular movements, including flexion, extension, hyperextension, abduction, adduction, and circumduction. **Flexion**, or bending, occurs when the angle between the bones decreases. Moving the forearm upward at the elbow or moving the wrist to move the hand toward the forearm are examples of flexion. **Extension** is the opposite of flexion in that the angle between the bones of a joint increases. Straightening a limb after flexion is an example of extension. Extension past the regular anatomical position is referred to as **hyperextension**. This includes moving the neck back to look upward, or bending the wrist so that the hand moves away from the forearm.

**Abduction** occurs when a bone moves away from the midline of the body. Examples of abduction are moving the arms or legs laterally to lift them straight out to the side. **Adduction** is the movement of a bone toward the midline of the body. Movement of the limbs inward after abduction is an example of adduction. **Circumduction** is the movement of a limb in a circular motion, as in moving the arm in a circular motion.

### **Rotational Movement**

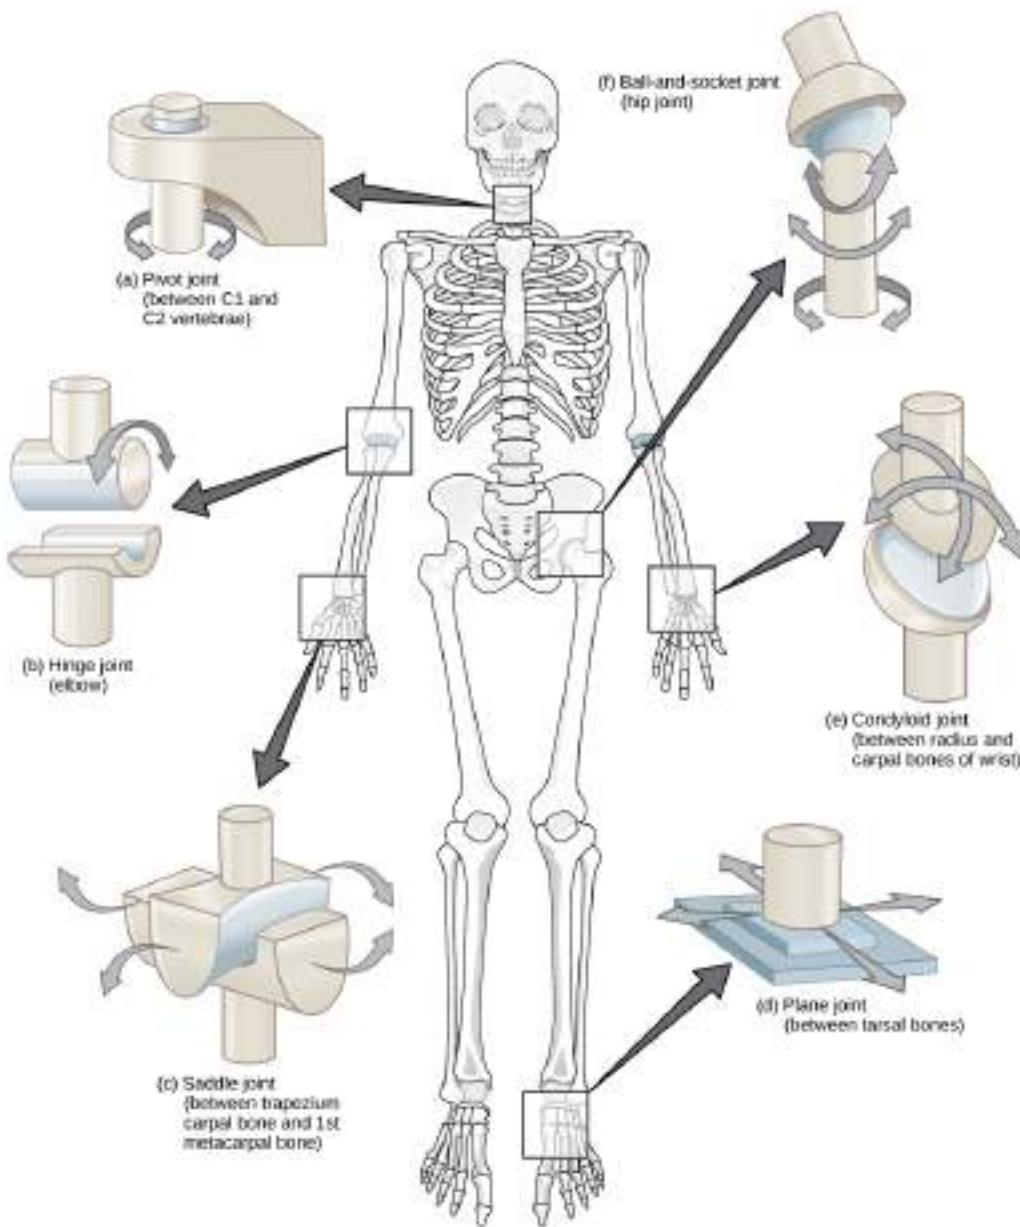

**Rotational movement** is the movement of a bone as it rotates around its longitudinal axis. Rotation can be toward the midline of the body, which is referred to as **medial rotation**, or away from the midline of the body, which is referred to as **lateral rotation**. Movement of the head from side to side is an example of rotation.

### **Special Movements**

Some movements that cannot be classified as gliding, angular, or rotational are called special movements. **Inversion** involves the soles of the feet moving inward, toward the midline of the body. **Eversion** is the opposite of inversion, movement of the sole of the foot outward, away from the midline of the body. **Protraction** is the anterior movement of a bone in the horizontal plane. **Retraction** occurs as a joint moves back into position after protraction. Protraction and retraction can be seen in the movement of the mandible as the jaw is thrust outwards and then back inwards. **Elevation** is the movement of a bone upward, such as when the shoulders are shrugged, lifting the scapulae. **Depression** is the opposite of elevation—movement downward of a bone, such as after the shoulders are shrugged and the scapulae return to their normal position from an elevated position. **Dorsiflexion** is a bending at the ankle such that the toes are lifted toward the knee. **Plantar flexion** is a bending at the ankle when the heel is lifted, such as when standing on the toes. **Supination** is the movement of the radius and ulna bones of the forearm so that the palm faces forward. **Pronation** is the opposite movement, in which the palm faces backward. **Opposition** is the movement of the thumb toward the fingers of the same hand, making it possible to grasp and hold objects.

## **Types of Synovial Joints**

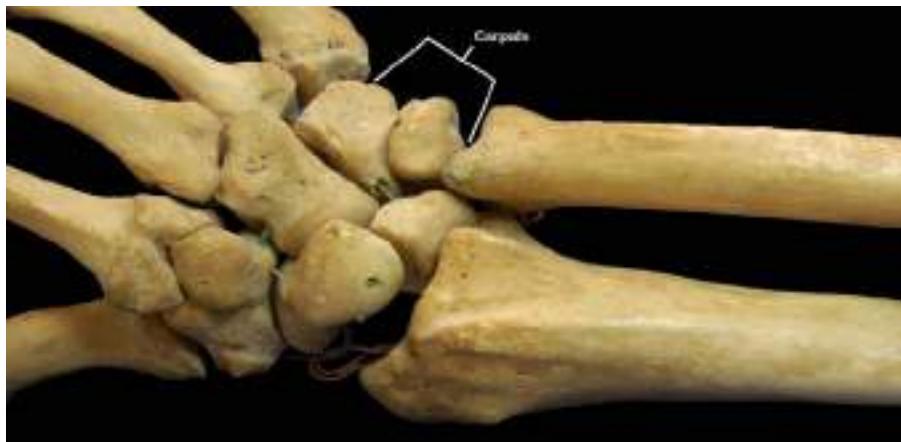

Synovial joints are further classified into six different categories on the basis of the shape and structure of the joint. The shape of the joint affects the type of movement permitted by the joint (Figure 29.26). These joints can be described as planar, hinge, pivot, condyloid, saddle, or ball-and-socket joints.

**Figure 29.26** Different types of joints allow different types of movement. Planar, hinge, pivot, condyloid, saddle, and ball-and-socket are all types of synovial joints.

### Planar Joints

**Planar joints** have bones with articulating surfaces that are flat or slightly curved faces. These joints allow for gliding movements, and so the joints are sometimes referred to as gliding joints. The range of motion is limited in these joints and does not involve rotation. Planar joints are found in the carpal bones in the hand and the tarsal bones of the foot, as well as between vertebrae (Figure 29.27).

**Figure 29.27** The joints of the carpal bones in the wrist are examples of planar joints. (credit: modification of work by Brian C. Goss)

### Hinge Joints

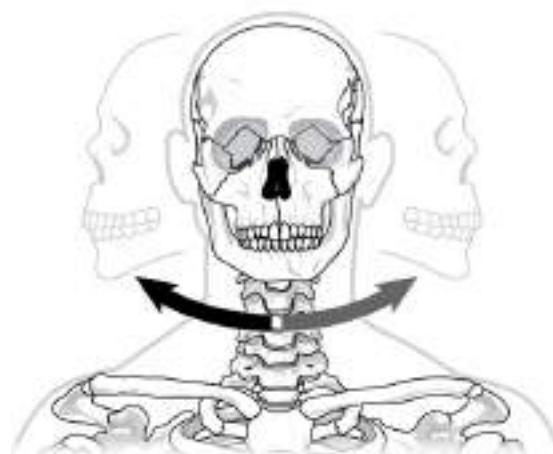

In **hinge joints**, the slightly rounded end of one bone fits into the slightly hollow end of the other bone. In this way, one bone moves while the other remains stationary, like the hinge of a door. The elbow is an example of a hinge joint. The knee is sometimes classified as a modified hinge joint (**Figure 29.28**).

**Figure 29.28** The elbow joint, where the radius articulates with the humerus, is an example of a hinge joint. (credit: modification of work by Brian C. Goss)

### Pivot Joints

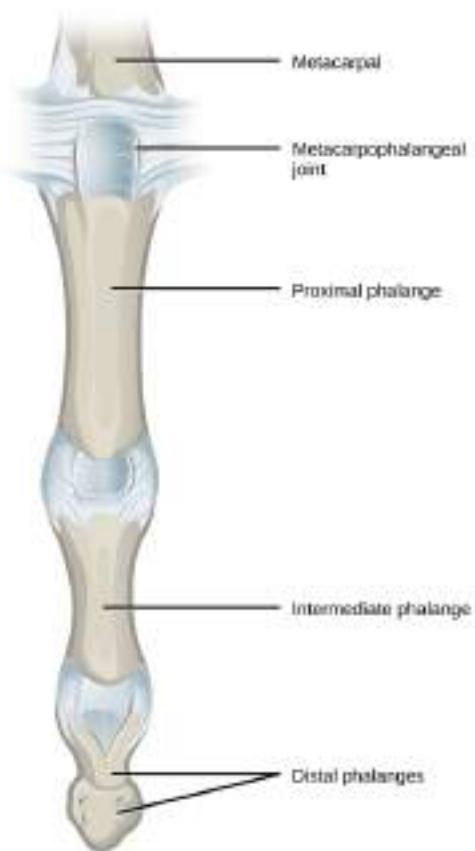

**Pivot joints** consist of the rounded end of one bone fitting into a ring formed by the other bone. This structure allows rotational movement, as the rounded bone moves around its own axis. An example of a pivot joint is the joint of the first and second vertebrae of the neck that allows the head to move back and forth (**Figure 29.29**). The joint of the wrist that allows the palm of the hand to be turned up and down is also a pivot joint.

**Figure 29.29** The joint in the neck that allows the head to move back and forth is an example of a pivot joint.

#### Condyloid Joints

**Condyloid joints** consist of an oval-shaped end of one bone fitting into a similarly oval-shaped hollow of another bone (**Figure 29.30**). This is also sometimes called an ellipsoidal joint. This type of joint allows angular movement along two axes, as seen in the joints of the wrist and fingers, which can move both side to side and up and down.

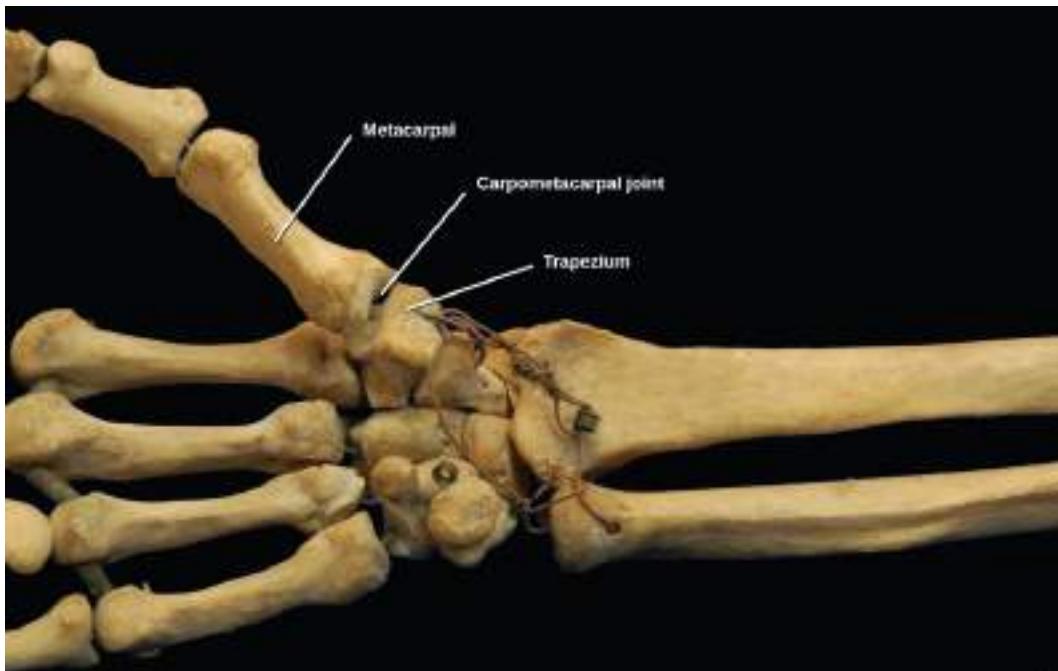

**Figure 29.30** The metacarpophalangeal joints in the finger are examples of condyloid joints. (credit: modification of work by Gray's Anatomy)

#### Saddle Joints

**Saddle joints** are so named because the ends of each bone resemble a saddle, with concave and convex portions that fit together. Saddle joints allow angular movements similar to condyloid joints but with a greater range of motion. An example of a saddle joint is the thumb joint, which can move back and forth and up and down, but more freely than the wrist or

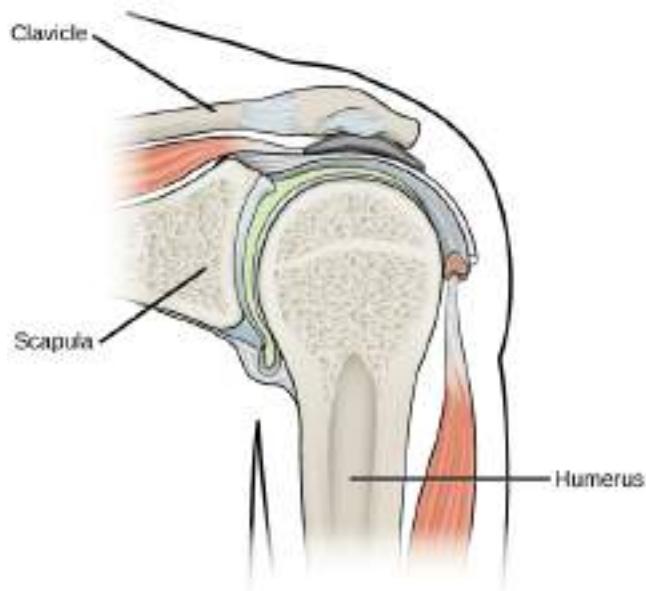

fingers (Figure 29.31).

**Figure 29.31** The carpometacarpal joints in the thumb are examples of saddle joints. (credit: modification of work by Brian C. Goss)

#### **Ball-and-Socket Joints**

**Ball-and-socket joints** possess a rounded, ball-like end of one bone fitting into a cuplike socket of another bone. This organization allows the greatest range of motion, as all movement types are possible in all directions. Examples of ball-and-socket joints are the shoulder and hip joints (Figure 29.32).

**Figure 29.32** The shoulder joint is an example of a ball-and-socket joint.

Watch this **animation** ([http://openstaxcollege.org/l/synovial\\_joints](http://openstaxcollege.org/l/synovial_joints)) showing the six types of synovial joints.

The shoulder and hip joints are an example of a ball-and-socket joint which \_\_\_\_.

- a. permits extension
- b. allows only gliding movement
- c. allows abduction or adduction
- d. allows rotation

## career CONNECTION

### Rheumatologist

Rheumatologists are medical doctors who specialize in the diagnosis and treatment of disorders of the joints, muscles, and bones. They diagnose and treat diseases such as arthritis, musculoskeletal disorders, osteoporosis, and autoimmune diseases such as ankylosing spondylitis and rheumatoid arthritis.

Rheumatoid arthritis (RA) is an inflammatory disorder that primarily affects the synovial joints of the hands, feet, and cervical spine. Affected joints become swollen, stiff, and painful. Although it is known that RA is an autoimmune disease in which the body's immune system mistakenly attacks healthy tissue, the cause of RA remains unknown. Immune cells from the blood enter joints and the synovium causing cartilage breakdown, swelling, and inflammation of the joint lining. Breakdown of cartilage causes bones to rub against each other causing pain. RA is more common in women than men and the age of onset is usually 40–50 years of age.

Rheumatologists can diagnose RA on the basis of symptoms such as joint inflammation and pain, X-ray and MRI imaging, and blood tests. Arthrography is a type of medical imaging of joints that uses a contrast agent, such as a dye, that is opaque to X-rays. This allows the soft tissue structures of joints—such as cartilage, tendons, and ligaments—to be visualized. An arthrogram differs from a regular X-ray by showing the surface of soft tissues lining the joint in addition to joint bones. An arthrogram allows early degenerative changes in joint cartilage to be detected before bones become affected.

There is currently no cure for RA; however, rheumatologists have a number of treatment options available. Early stages can be treated with rest of the affected joints by using a cane or by using joint splints that minimize inflammation. When inflammation has decreased, exercise can be used to strengthen the muscles that surround the joint and to maintain joint flexibility. If joint damage is more extensive, medications can be used to relieve pain and decrease inflammation. Anti-inflammatory drugs such as aspirin, topical pain relievers, and corticosteroid injections may be used. Surgery may be required in cases in which joint damage is severe.

## 29.4 | Muscle Contraction and Locomotion

In this section, you will explore the following questions:

- What are the different types of muscle tissue?
- What is the role of muscle contraction in locomotion?

### Connection for AP® Courses

Muscles move bones, and, in turn, muscle contraction is dependent upon input from the nervous systems. The activities at the neuromuscular junction are similar to the activities occurring at the synapses between neurons.

There are approximately 650 skeletal muscles in the human body, each of which is composed of muscle fibers. (The body also contains specialized smooth and cardiac muscle tissue.) In addition to the collection of organelles typical of eukaryotic cells, each muscle fiber contains myofibrils, which, in turn, consist of arrangements of protein filaments called actin and myosin. In the sliding filament model of muscle contraction, the thicker myosin filaments have cross-bridges that attach and detach to thinner actin filaments. The binding of myosin to actin causes the actin filaments to slide, shortening the muscle fiber. ATP produced in cellular respiration provides the energy needed for contraction. However, contraction requires a signal from the nervous system (excitation-contraction coupling).

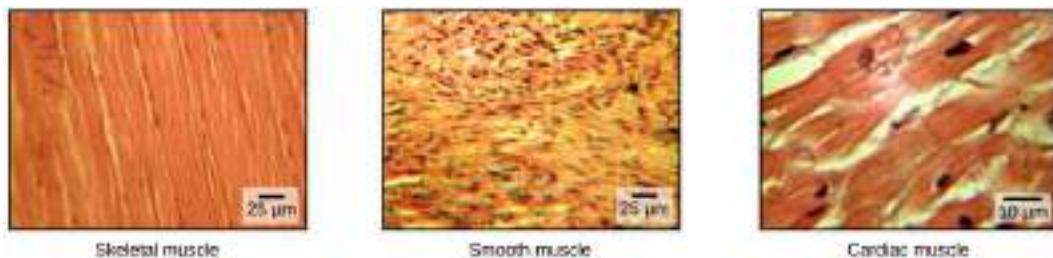

Nerve impulses traveling down motor neurons cause the release of the acetylcholine from vesicles in the axon terminus into the synapse between the neuron and the muscle fiber. Acetylcholine binds to receptors on the plasma membrane (sarcolemma) of the muscle fiber, allowing an action potential to move to the endoplasmic reticulum where calcium ions are stored. When  $\text{Ca}^{2+}$  is released in response to the change in voltage, it binds to actin, causing actin filaments to shift position and revealing myosin binding sites for the cross-bridges. The muscle contracts until the nerve impulse stops and  $\text{Ca}^{2+}$  returns to its storage sites. The enzyme acetylcholinesterase removes lingering acetylcholine from the synaptic cleft.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Muscle cells are specialized for contraction. Muscles allow for motions such as walking, and they also facilitate bodily processes such as respiration and digestion. The body contains three types of muscle tissue: skeletal muscle, cardiac muscle, and smooth muscle (Figure 29.33).

**Figure 29.33** The body contains three types of muscle tissue: skeletal muscle, smooth muscle, and cardiac muscle, visualized here using light microscopy. Smooth muscle cells are short, tapered at each end, and have only one plump nucleus in each. Cardiac muscle cells are branched and striated, but short. The cytoplasm may branch, and they have one nucleus in the center of the cell. (credit: modification of work by NCI, NIH; scale-bar data from Matt Russell)

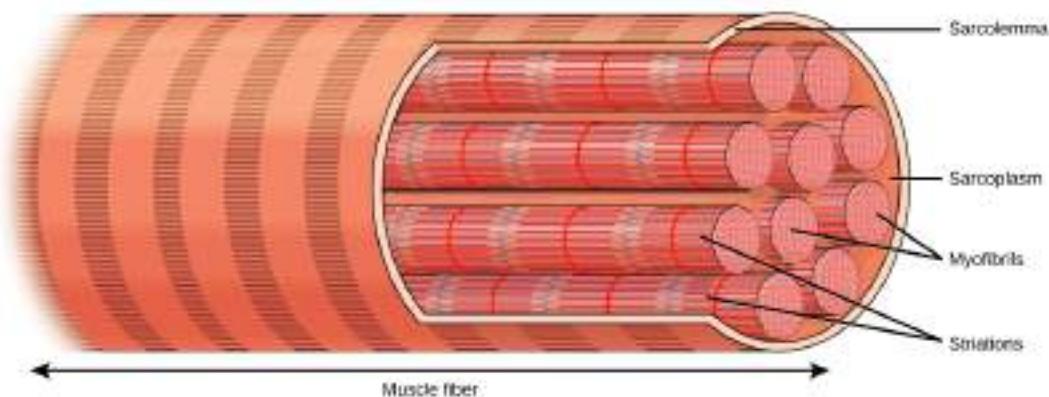

**Skeletal muscle tissue** forms skeletal muscles, which attach to bones or skin and control locomotion and any movement that can be consciously controlled. Because it can be controlled by thought, skeletal muscle is also called voluntary muscle. Skeletal muscles are long and cylindrical in appearance; when viewed under a microscope, skeletal muscle tissue has a striped or striated appearance. The striations are caused by the regular arrangement of contractile proteins (actin and myosin). **Actin** is a globular contractile protein that interacts with **myosin** for muscle contraction. Skeletal muscle also has multiple nuclei present in a single cell.

**Smooth muscle tissue** occurs in the walls of hollow organs such as the intestines, stomach, and urinary bladder, and around passages such as the respiratory tract and blood vessels. Smooth muscle has no striations, is not under voluntary control, has only one nucleus per cell, is tapered at both ends, and is called involuntary muscle.

**Cardiac muscle tissue** is only found in the heart, and cardiac contractions pump blood throughout the body and maintain blood pressure. Like skeletal muscle, cardiac muscle is striated, but unlike skeletal muscle, cardiac muscle cannot be consciously controlled and is called involuntary muscle. It has one nucleus per cell, is branched, and is distinguished by the presence of intercalated disks.

## Skeletal Muscle Fiber Structure

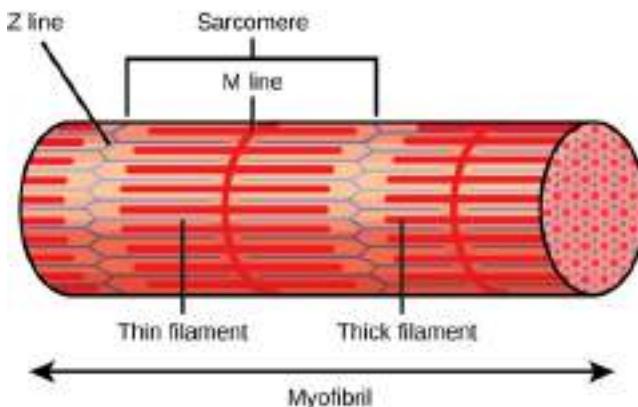

Each skeletal muscle fiber is a skeletal muscle cell. These cells are incredibly large, with diameters of up to 100  $\mu\text{m}$  and lengths of up to 30 cm. The plasma membrane of a skeletal muscle fiber is called the **sarcolemma**. The sarcolemma is the site of action potential conduction, which triggers muscle contraction. Within each muscle fiber are **myofibrils**—long cylindrical structures that lie parallel to the muscle fiber. Myofibrils run the entire length of the muscle fiber, and because they are only approximately 1.2  $\mu\text{m}$  in diameter, hundreds to thousands can be found inside one muscle fiber. They attach to the sarcolemma at their ends, so that as myofibrils shorten, the entire muscle cell contracts (Figure 29.34).

**Figure 29.34** A skeletal muscle cell is surrounded by a plasma membrane called the sarcolemma with a cytoplasm called the sarcoplasm. A muscle fiber is composed of many fibrils, packaged into orderly units.

The striated appearance of skeletal muscle tissue is a result of repeating bands of the proteins actin and myosin that are present along the length of myofibrils. Dark A bands and light I bands repeat along myofibrils, and the alignment of myofibrils in the cell causes the entire cell to appear striated or banded.

Each I band has a dense line running vertically through the middle called a Z disc or Z line. The Z discs mark the border of units called **sarcomeres**, which are the functional units of skeletal muscle. One sarcomere is the space between two consecutive Z discs and contains one entire A band and two halves of an I band, one on either side of the A band. A myofibril is composed of many sarcomeres running along its length, and as the sarcomeres individually contract, the myofibrils and muscle cells shorten (**Figure 29.35**).

**Figure 29.35** A sarcomere is the region from one Z line to the next Z line. Many sarcomeres are present in a myofibril, resulting in the striation pattern characteristic of skeletal muscle.

Myofibrils are composed of smaller structures called **myofilaments**. There are two main types of filaments: thick filaments and thin filaments; each has different compositions and locations. **Thick filaments** occur only in the A band of a myofibril. **Thin filaments** attach to a protein in the Z disc called alpha-actinin and occur across the entire length of the I band and partway into the A band. The region at which thick and thin filaments overlap has a dense appearance, as there is little space between the filaments. Thin filaments do not extend all the way into the A bands, leaving a central region of the A band that only contains thick filaments. This central region of the A band looks slightly lighter than the rest of the A band and is called the H zone. The middle of the H zone has a vertical line called the M line, at which accessory proteins hold together thick filaments. Both the Z disc and the M line hold myofilaments in place to maintain the structural arrangement and layering of the myofibril. Myofibrils are connected to each other by intermediate, or desmin, filaments that attach to the Z disc.

Thick and thin filaments are themselves composed of proteins. Thick filaments are composed of the protein myosin. The tail of a myosin molecule connects with other myosin molecules to form the central region of a thick filament near the M line, whereas the heads align on either side of the thick filament where the thin filaments overlap. The primary component of thin filaments is the actin protein. Two other components of the thin filament are tropomyosin and troponin. Actin has binding sites for myosin attachment. Strands of tropomyosin block the binding sites and prevent actin–myosin interactions when the muscles are at rest. Troponin consists of three globular subunits. One subunit binds to tropomyosin, one subunit

binds to actin, and one subunit binds  $\text{Ca}^{2+}$  ions.

## Sliding Filament Model of Contraction

For a muscle cell to contract, the sarcomere must shorten. However, thick and thin filaments—the components of sarcomeres—do not shorten. Instead, they slide by one another, causing the sarcomere to shorten while the filaments remain the same length. The sliding filament theory of muscle contraction was developed to fit the differences observed in the named bands on the sarcomere at different degrees of muscle contraction and relaxation. The mechanism of contraction is the binding of myosin to actin, forming cross-bridges that generate filament movement (Figure 29.36).

**Figure 29.36** When (a) a sarcomere (b) contracts, the Z lines move closer together and the I band gets smaller. The A band stays the same width and, at full contraction, the thin filaments overlap.

When a sarcomere shortens, some regions shorten whereas others stay the same length. A sarcomere is defined as the distance between two consecutive Z discs or Z lines; when a muscle contracts, the distance between the Z discs is reduced. The H zone—the central region of the A zone—contains only thick filaments and is shortened during contraction. The I band contains only thin filaments and also shortens. The A band does not shorten—it remains the same length—but A bands of different sarcomeres move closer together during contraction, eventually disappearing. Thin filaments are pulled by the thick filaments toward the center of the sarcomere until the Z discs approach the thick filaments. The zone of overlap, in which thin filaments and thick filaments occupy the same area, increases as the thin filaments move inward.

## ATP and Muscle Contraction

The motion of muscle shortening occurs as myosin heads bind to actin and pull the actin inwards. This action requires energy, which is provided by ATP. Myosin binds to actin at a binding site on the globular actin protein. Myosin has another binding site for ATP at which enzymatic activity hydrolyzes ATP to ADP, releasing an inorganic phosphate molecule and energy.

ATP binding causes myosin to release actin, allowing actin and myosin to detach from each other. After this happens, the newly bound ATP is converted to ADP and inorganic phosphate,  $P_i$ . The enzyme at the binding site on myosin is called ATPase. The energy released during ATP hydrolysis changes the angle of the myosin head into a “cocked” position. The myosin head is then in a position for further movement, possessing potential energy, but ADP and  $P_i$  are still attached. If actin binding sites are covered and unavailable, the myosin will remain in the high energy configuration with ATP hydrolyzed, but still attached.

If the actin binding sites are uncovered, a cross-bridge will form; that is, the myosin head spans the distance between the actin and myosin molecules.  $P_i$  is then released, allowing myosin to expend the stored energy as a conformational change. The myosin head moves toward the M line, pulling the actin along with it. As the actin is pulled, the filaments move approximately 10 nm toward the M line. This movement is called the power stroke, as it is the step at which force is

produced. As the actin is pulled toward the M line, the sarcomere shortens and the muscle contracts.

When the myosin head is “cocked,” it contains energy and is in a high-energy configuration. This energy is expended as the myosin head moves through the power stroke; at the end of the power stroke, the myosin head is in a low-energy position. After the power stroke, ADP is released; however, the cross-bridge formed is still in place, and actin and myosin are bound together. ATP can then attach to myosin, which allows the cross-bridge cycle to start again and further muscle contraction can occur ([Figure 29.37](#)).

Watch this [video](#) ([http://openstaxcollege.org/l/contract\\_muscle](http://openstaxcollege.org/l/contract_muscle)) explaining how a muscle contraction is signaled.

Why can't actin and myosin interact in the absence of calcium?

- a. Actin binding sites are covered by acetylcholine to which the troponin complex is attached. This complex is calcium sensitive. Troponin binds to the calcium and moves the tropomyosin binding site.
- b. Myosin binding sites are covered by the troponin complex to which is attached tropomyosin. Tropomyosin is calcium sensitive. It binds to the calcium and moves the troponin binding site.
- c. Actin binding sites are covered by tropomyosin to which the troponin complex is attached. This complex is calcium sensitive. Troponin binds to the calcium and moves the tropomyosin binding site.
- d. Myosin binding sites are covered by tropomyosin to which the troponin complex is attached. This complex is calcium sensitive. Troponin binds to the calcium and moves the tropomyosin binding site.

## visual CONNECTION

The diagram illustrates the cross-bridge muscle contraction cycle through five numbered stages:

- ① The active site on actin is exposed as  $\text{Ca}^{2+}$  binds troponin.
- ② The myosin head forms a cross-bridge with actin.
- ③ During the power stroke, the myosin head bends, and ADP and phosphate are released.
- ④ A new molecule of ATP attaches to the myosin head, causing the cross-bridge to detach.
- ⑤ ATP hydrolyzes to ADP and phosphate, which returns the myosin to the "cocked" position.

Labels in the diagram include: Troponin,  $\text{Ca}^{2+}$ , Tropomyosin, Active site, Myosin head, ADP, P, and Actin.

**Figure 29.37** The cross-bridge muscle contraction cycle, which is triggered by  $\text{Ca}^{2+}$  binding to the actin active site, is shown. With each contraction cycle, actin moves relative to myosin.

Which of the following statements about the “power stroke” of muscle contraction is true?

- It occurs when ATP is hydrolyzed to ADP and phosphate.
- It occurs when a new molecule of ATP attaches to the myosin head.
- It occurs when ADP and phosphate separate from the myosin head.
- It occurs when ADP and phosphate separate from the actin active site.

View this **animation** ([http://openstaxcollege.org/l/muscle\\_contract](http://openstaxcollege.org/l/muscle_contract)) of the cross-bridge muscle contraction.

Describe the steps involved in the cross-bridge muscle contraction process.

- The myosin head forms a cross-bridge with actin, which initiates the power stroke. During the power stroke, the myosin head bends with the release of ADP and inorganic phosphate. Another ATP binds to the myosin head, causing the cross-bridge to detach and returning myosin to the cocked configuration.
- The actin head forms a cross-bridge with myosin which initiates the power stroke. During the power stroke, the actin head bends with the release of ADP and inorganic phosphate. Another ATP binds the myosin head, causing the cross-bridge to detach and returning myosin to the cocked configuration.
- The myosin head forms a cross-bridge with actin which initiates the power stroke. During the power stroke, the myosin head bends with release of ADP and inorganic phosphate. Another ATP binds to the actin head, causing the cross-bridge to detach and returning actin to the cocked configuration.
- The actin head forms a cross-bridge with myosin, which initiates the power stroke. During the power stroke, the actin head bends with the release of ADP and inorganic phosphate. Another ATP binds to the actin head, causing the cross-bridge to detach and returning actin to the cocked configuration.

## Regulatory Proteins

When a muscle is in a resting state, actin and myosin are separated. To keep actin from binding to the active site on myosin, regulatory proteins block the molecular binding sites. **Tropomyosin** blocks myosin binding sites on actin molecules, preventing cross-bridge formation and preventing contraction in a muscle without nervous input. **Troponin** binds to tropomyosin and helps to position it on the actin molecule; it also binds calcium ions.

To enable a muscle contraction, tropomyosin must change conformation, uncovering the myosin-binding site on an actin molecule and allowing cross-bridge formation. This can only happen in the presence of calcium, which is kept at extremely low concentrations in the sarcoplasm. If present, calcium ions bind to troponin, causing conformational changes in troponin that allow tropomyosin to move away from the myosin binding sites on actin. Once the tropomyosin is removed, a cross-bridge can form between actin and myosin, triggering contraction. Cross-bridge cycling continues until  $\text{Ca}^{2+}$  ions and ATP are no longer available and tropomyosin again covers the binding sites on actin.

## Excitation–Contraction Coupling

Excitation–contraction coupling is the link (transduction) between the action potential generated in the sarcolemma and the start of a muscle contraction. The trigger for calcium release from the sarcoplasmic reticulum into the sarcoplasm is a neural signal. Each skeletal muscle fiber is controlled by a motor neuron, which conducts signals from the brain or spinal cord to the muscle. The area of the sarcolemma on the muscle fiber that interacts with the neuron is called the **motor end plate**. The end of the neuron's axon is called the synaptic terminal, and it does not actually contact the motor end plate. A small space called the synaptic cleft separates the synaptic terminal from the motor end plate. Electrical signals travel along the neuron's axon, which branches through the muscle and connects to individual muscle fibers at a neuromuscular junction.

The ability of cells to communicate electrically requires that the cells expend energy to create an electrical gradient across their cell membranes. This charge gradient is carried by ions, which are differentially distributed across the membrane. Each ion exerts an electrical influence and a concentration influence. Just as milk will eventually mix with coffee without the need to stir, ions also distribute themselves evenly, if they are permitted to do so. In this case, they are not permitted to return to an evenly mixed state.

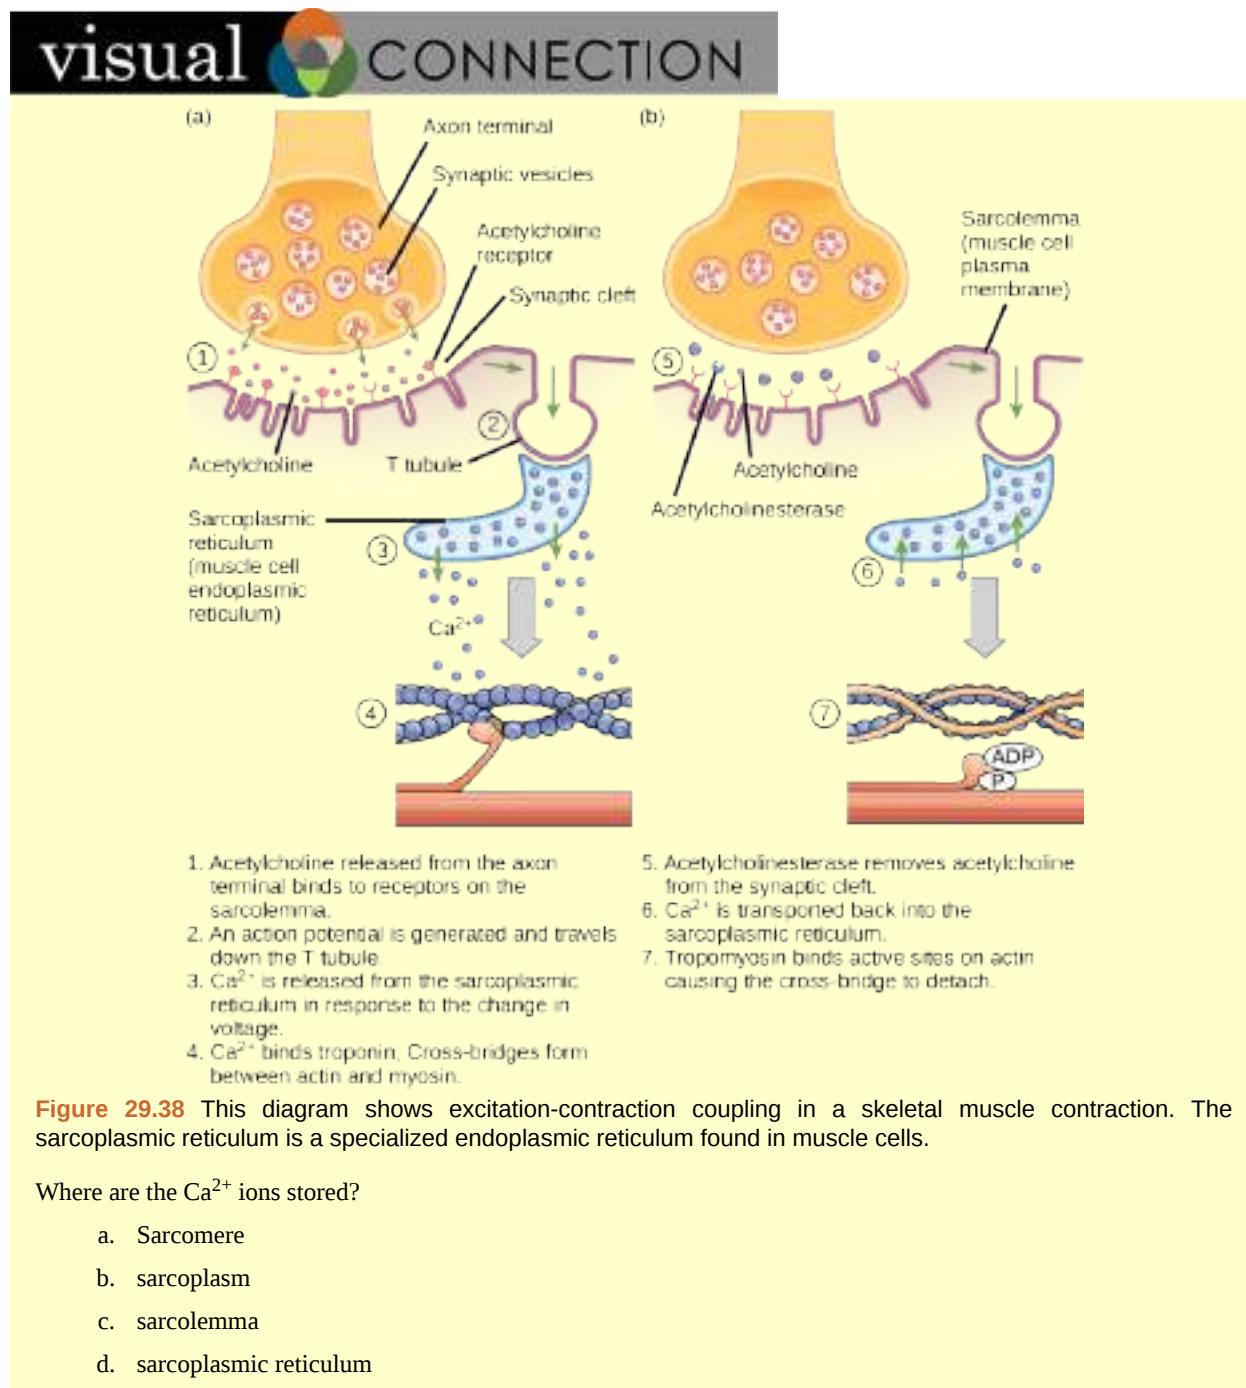

The sodium–potassium ATPase uses cellular energy to move  $\text{K}^+$  ions inside the cell and  $\text{Na}^+$  ions outside. This alone accumulates a small electrical charge, but a big concentration gradient. There is lots of  $\text{K}^+$  in the cell and lots of  $\text{Na}^+$  outside the cell. Potassium is able to leave the cell through  $\text{K}^+$  channels that are open 90% of the time, and it does. However,  $\text{Na}^+$

channels are rarely open, so  $\text{Na}^+$  remains outside the cell. When  $\text{K}^+$  leaves the cell, obeying its concentration gradient, that effectively leaves a negative charge behind. So at rest, there is a large concentration gradient for  $\text{Na}^+$  to enter the cell, and there is an accumulation of negative charges left behind in the cell. This is the resting membrane potential. Potential in this context means a separation of electrical charge that is capable of doing work. It is measured in volts, just like a battery. However, the transmembrane potential is considerably smaller (0.07 V); therefore, the small value is expressed as millivolts (mV) or 70 mV. Because the inside of a cell is negative compared with the outside, a minus sign signifies the excess of negative charges inside the cell,  $-70 \text{ mV}$ .

If an event changes the permeability of the membrane to  $\text{Na}^+$  ions, they will enter the cell. That will change the voltage. This is an electrical event, called an action potential, that can be used as a cellular signal. Communication occurs between nerves and muscles through neurotransmitters. Neuron action potentials cause the release of neurotransmitters from the synaptic terminal into the synaptic cleft, where they can then diffuse across the synaptic cleft and bind to a receptor molecule on the motor end plate. The motor end plate possesses junctional folds—folds in the sarcolemma that create a large surface area for the neurotransmitter to bind to receptors. The receptors are actually sodium channels that open to allow the passage of  $\text{Na}^+$  into the cell when they receive neurotransmitter signal.

Acetylcholine (ACh) is a neurotransmitter released by motor neurons that binds to receptors in the motor end plate. Neurotransmitter release occurs when an action potential travels down the motor neuron's axon, resulting in altered permeability of the synaptic terminal membrane and an influx of calcium. The  $\text{Ca}^{2+}$  ions allow synaptic vesicles to move to and bind with the presynaptic membrane (on the neuron), and release neurotransmitter from the vesicles into the synaptic cleft. Once released by the synaptic terminal, ACh diffuses across the synaptic cleft to the motor end plate, where it binds with ACh receptors. As a neurotransmitter binds, these ion channels open, and  $\text{Na}^+$  ions cross the membrane into the muscle cell. This reduces the voltage difference between the inside and outside of the cell, which is called depolarization. As ACh binds at the motor end plate, this depolarization is called an end-plate potential. The depolarization then spreads along the sarcolemma, creating an action potential as sodium channels adjacent to the initial depolarization site sense the change in voltage and open. The action potential moves across the entire cell, creating a wave of depolarization.

ACh is broken down by the enzyme **acetylcholinesterase** (AChE) into acetyl and choline. AChE resides in the synaptic cleft, breaking down ACh so that it does not remain bound to ACh receptors, which would cause unwanted extended muscle contraction ([Figure 29.38](#)).

**Figure 29.38** This diagram shows excitation-contraction coupling in a skeletal muscle contraction. The sarcoplasmic reticulum is a specialized endoplasmic reticulum found in muscle cells.

Where are the Ca<sup>2+</sup> ions stored?

- Sarcomere
- sarcoplasm
- sarcolemma
- sarcoplasmic reticulum

After depolarization, the membrane returns to its resting state. This is called repolarization, during which voltage-gated sodium channels close. Potassium channels continue at 90% conductance. Because the plasma membrane sodium–potassium ATPase always transports ions, the resting state (negatively charged inside relative to the outside) is restored. The period immediately following the transmission of an impulse in a nerve or muscle, in which a neuron or muscle cell regains its ability to transmit another impulse, is called the refractory period. During the refractory period, the membrane cannot generate another action potential. The refractory period allows the voltage-sensitive ion channels to return to their resting configurations. The sodium potassium ATPase continually moves Na<sup>+</sup> back out of the cell and K<sup>+</sup> back into the cell, and the K<sup>+</sup> leaks out leaving negative charge behind. Very quickly, the membrane repolarizes, so that it can again be depolarized.

## Control of Muscle Tension

Neural control initiates the formation of actin–myosin cross-bridges, leading to the sarcomere shortening involved in muscle contraction. These contractions extend from the muscle fiber through connective tissue to pull on bones, causing skeletal movement. The pull exerted by a muscle is called tension, and the amount of force created by this tension can vary. This enables the same muscles to move very light objects and very heavy objects. In individual muscle fibers, the amount of tension produced depends on the cross-sectional area of the muscle fiber and the frequency of neural stimulation.

The number of cross-bridges formed between actin and myosin determine the amount of tension that a muscle fiber can produce. Cross-bridges can only form where thick and thin filaments overlap, allowing myosin to bind to actin. If more cross-bridges are formed, more myosin will pull on actin, and more tension will be produced.

The ideal length of a sarcomere during production of maximal tension occurs when thick and thin filaments overlap to the greatest degree. If a sarcomere at rest is stretched past an ideal resting length, thick and thin filaments do not overlap to the greatest degree, and fewer cross-bridges can form. This results in fewer myosin heads pulling on actin, and less tension is produced. As a sarcomere is shortened, the zone of overlap is reduced as the thin filaments reach the H zone, which is composed of myosin tails. Because it is myosin heads that form cross-bridges, actin will not bind to myosin in this zone, reducing the tension produced by this myofiber. If the sarcomere is shortened even more, thin filaments begin to overlap with each other—reducing cross-bridge formation even further, and producing even less tension. Conversely, if the sarcomere is stretched to the point at which thick and thin filaments do not overlap at all, no cross-bridges are formed and no tension is produced. This amount of stretching does not usually occur because accessory proteins, internal sensory nerves, and connective tissue oppose extreme stretching.

The primary variable determining force production is the number of myofibers within the muscle that receive an action potential from the neuron that controls that fiber. When using the biceps to pick up a pencil, the motor cortex of the brain only signals a few neurons of the biceps, and only a few myofibers respond. In vertebrates, each myofiber responds fully if stimulated. When picking up a piano, the motor cortex signals all of the neurons in the biceps and every myofiber participates. This is close to the maximum force the muscle can produce. As mentioned above, increasing the frequency of action potentials (the number of signals per second) can increase the force a bit more, because the tropomyosin is flooded with calcium.

#### Think About It

- The deadly nerve gas Sarin irreversibly inhibits the enzyme, acetylcholinesterase. What effect would Sarin have on muscle contraction?
- How are the activities at the neuromuscular junction similar to the activities occurring at the synapses between neurons?

## KEY TERMS

**abduction** when a bone moves away from the midline of the body

**acetylcholinesterase** (AChE) enzyme that breaks down ACh into acetyl and choline

**actin** globular contractile protein that interacts with myosin for muscle contraction

**adduction** movement of the limbs inward after abduction

**amphiarthrosis** joint that allows slight movement; includes syndesmoses and symphyses

**angular movement** produced when the angle between the bones of a joint changes

**appendicular skeleton** composed of the bones of the upper limbs, which function to grasp and manipulate objects, and the lower limbs, which permit locomotion

**appositional growth** increase in the diameter of bones by the addition of bone tissue at the surface of bones

**articulation** any place where two bones are joined

**auditory ossicle** (also, middle ear) transduces sounds from the air into vibrations in the fluid-filled cochlea

**axial skeleton** forms the central axis of the body and includes the bones of the skull, the ossicles of the middle ear, the hyoid bone of the throat, the vertebral column, and the thoracic cage (ribcage)

**ball-and-socket joint** joint with a rounded, ball-like end of one bone fitting into a cuplike socket of another bone

**bone** (also, osseous tissue) connective tissue that constitutes the endoskeleton

**bone remodeling** replacement of old bone tissue by new bone tissue

**calcification** process of deposition of mineral salts in the collagen fiber matrix that crystallizes and hardens the tissue

**cardiac muscle** tissue muscle tissue found only in the heart; cardiac contractions pump blood throughout the body and maintain blood pressure

**carpus** eight bones that comprise the wrist

**cartilaginous joint** joint in which the bones are connected by cartilage

**circumduction** movement of a limb in a circular motion.

**clavicle** S-shaped bone that positions the arms laterally

**compact bone** forms the hard external layer of all bones

**condyloid joint** oval-shaped end of one bone fitting into a similarly oval-shaped hollow of another bone

**coxal bone** hip bone

**cranial bone** one of eight bones that form the cranial cavity that encloses the brain and serves as an attachment site for the muscles of the head and neck

**depression** movement downward of a bone, such as after the shoulders are shrugged and the scapulae return to their normal position from an elevated position; opposite of elevation

**diaphysis** central shaft of bone, contains bone marrow in a marrow cavity

**diarthrosis** joint that allows for free movement of the joint; found in synovial joints

**dorsiflexion** bending at the ankle such that the toes are lifted toward the knee

**elevation** movement of a bone upward, such as when the shoulders are shrugged, lifting the scapulae

**endochondral ossification** process of bone development from hyaline cartilage

**endoskeleton** skeleton of living cells that produce a hard, mineralized tissue located within the soft tissue of organisms

**epiphyseal plate** region between the diaphysis and epiphysis that is responsible for the lengthwise growth of long bones

**epiphysis** rounded end of bone, covered with articular cartilage and filled with red bone marrow, which produces blood cells

**eversion** movement of the sole of the foot outward, away from the midline of the body; opposite of inversion

**exoskeleton** a secreted cellular product external skeleton that consists of a hard encasement on the surface of an organism

**extension** movement in which the angle between the bones of a joint increases; opposite of flexion

**facial bone** one of the 14 bones that form the face; provides cavities for the sense organs (eyes, mouth, and nose) and attachment points for facial muscles

**femur** (also, thighbone) longest, heaviest, and strongest bone in the body

**fibrous joint** joint held together by fibrous connective tissue

**fibula** (also, calf bone) parallels and articulates with the tibia

**flat bone** thin and relatively broad bone found where extensive protection of organs is required or where broad surfaces of muscle attachment are required

**flexion** movement in which the angle between the bones decreases; opposite of extension

**forearm** extends from the elbow to the wrist and consists of two bones: the ulna and the radius

**gliding movement** when relatively flat bone surfaces move past each other

**gomphosis** the joint in which the tooth fits into the socket like a peg

**Haversian canal** contains the bone's blood vessels and nerve fibers

**hinge joint** slightly rounded end of one bone fits into the slightly hollow end of the other bone

**humerus** only bone of the arm

**hydrostatic skeleton** skeleton that consists of aqueous fluid held under pressure in a closed body compartment

**hyoid bone** lies below the mandible in the front of the neck

**hyperextension** extension past the regular anatomical position

**intervertebral disc** composed of fibrous cartilage; lies between adjacent vertebrae from the second cervical vertebra to the sacrum

**intramembranous ossification** process of bone development from fibrous membranes

**inversion** soles of the feet moving inward, toward the midline of the body

**irregular bone** bone with complex shapes; examples include vertebrae and hip bones

**joint** point at which two or more bones meet

**lamella** layer of compact tissue that surrounds a central canal called the Haversian canal

**lateral rotation** rotation away from the midline of the body

**long bone** bone that is longer than wide, and has a shaft and two ends

**lower limb** consists of the thigh, the leg, and the foot

**medial rotation** rotation toward the midline of the body

**metacarpus** five bones that comprise the palm

**metatarsal** one of the five bones of the foot

**motor end plate** sarcolemma of the muscle fiber that interacts with the neuron

**myofibril** long cylindrical structures that lie parallel to the muscle fiber

**myofilament** small structures that make up myofibrils

**myosin** contractile protein that interacts with actin for muscle contraction

**opposition** movement of the thumb toward the fingers of the same hand, making it possible to grasp and hold objects

**osseous tissue** connective tissue that constitutes the endoskeleton

**ossification** (also, osteogenesis) process of bone formation by osteoblasts

**osteoblast** bone cell responsible for bone formation

**osteoclast** large bone cells with up to 50 nuclei, responsible for bone remodeling

**osteocyte** mature bone cells and the main cell in bone tissue

**osteon** cylindrical structure aligned parallel to the long axis of the bone

**patella** (also, kneecap) triangular bone that lies anterior to the knee joint

**pectoral girdle** bones that transmit the force generated by the upper limbs to the axial skeleton

**pelvic girdle** bones that transmit the force generated by the lower limbs to the axial skeleton

**phalange** one of the bones of the fingers or toes

**pivot joint** joint with the rounded end of one bone fitting into a ring formed by the other bone

**planar joint** joint with bones whose articulating surfaces are flat

**plantar flexion** bending at the ankle such that the heel is lifted, such as when standing on the toes

**pronation** movement in which the palm faces backward

**protraction** anterior movement of a bone in the horizontal plane

**radius** bone located along the lateral (thumb) side of the forearm; articulates with the humerus at the elbow

**resorption** process by which osteoclasts release minerals stored in bones

**retraction** movement in which a joint moves back into position after protraction

**rib** one of 12 pairs of long, curved bones that attach to the thoracic vertebrae and curve toward the front of the body to form the ribcage

**rotational movement** movement of a bone as it rotates around its own longitudinal axis

**saddle joint** joint with concave and convex portions that fit together; named because the ends of each bone resemble a saddle

**sarcolemma** plasma membrane of a skeletal muscle fiber

**sarcomere** functional unit of skeletal muscle

**scapula** flat, triangular bone located at the posterior pectoral girdle

**sesamoid bone** small, flat bone shaped like a sesame seed; develops inside tendons

**short bone** bone that has the same width and length, giving it a cube-like shape

**skeletal muscle tissue** forms skeletal muscles, which attach to bones and control locomotion and any movement that can be consciously controlled

**skull** bone that supports the structures of the face and protects the brain

**smooth muscle** tissue occurs in the walls of hollow organs such as the intestines, stomach, and urinary bladder, and around passages such as the respiratory tract and blood vessels

**spongy bone tissue** forms the inner layer of all bones

**sternum** (also, breastbone) long, flat bone located at the front of the chest

**supination** movement of the radius and ulna bones of the forearm so that the palm faces forward

**suture** short fiber of connective tissue that holds the skull bones tightly in place; found only in the skull

**suture bone** small, flat, irregularly shaped bone that forms between the flat bones of the cranium

**sympysis** hyaline cartilage covers the end of the bone, but the connection between bones occurs through fibrocartilage; symphyses are found at the joints between vertebrae

**synarthrosis** joint that is immovable

**synchondrosis** bones joined by hyaline cartilage; synchondroses are found in the epiphyseal plates of growing bones in children

**syndesmosis** joint in which the bones are connected by a band of connective tissue, allowing for more movement than in a suture

**synovial joint** only joint that has a space between the adjoining bones

**tarsal** one of the seven bones of the ankle

**thick filament** a group of myosin molecules

**thin filament** two polymers of actin wound together along with tropomyosin and troponin

**thoracic cage** (also, ribcage) skeleton of the chest, which consists of the ribs, thoracic vertebrae, sternum, and costal cartilages

**tibia** (also, shinbone) large bone of the leg that is located directly below the knee

**trabeculae** lamellae that are arranged as rods or plates

**tropomyosin** acts to block myosin binding sites on actin molecules, preventing cross-bridge formation and preventing contraction until a muscle receives a neuron signal

**troponin** binds to tropomyosin and helps to position it on the actin molecule, and also binds calcium ions

**ulna** bone located on the medial aspect (pinky-finger side) of the forearm

**vertebral column** (also, spine) surrounds and protects the spinal cord, supports the head, and acts as an attachment point for ribs and muscles of the back and neck

## CHAPTER SUMMARY

### 29.1 Types of Skeletal Systems

The three types of skeleton designs are hydrostatic skeletons, exoskeletons, and endoskeletons. A hydrostatic skeleton is formed by a fluid-filled compartment held under hydrostatic pressure; movement is created by the muscles producing pressure on the fluid. An exoskeleton is a hard external skeleton that protects the outer surface of an organism and enables movement through muscles attached on the inside. An endoskeleton is an internal skeleton composed of hard, mineralized tissue that also enables movement by attachment to muscles. The human skeleton is an endoskeleton that is composed of the axial and appendicular skeleton. The axial skeleton is composed of the bones of the skull, ossicles of the ear, hyoid bone, vertebral column, and ribcage. The skull consists of eight cranial bones and 14 facial bones. Six bones make up the ossicles of the middle ear, while the hyoid bone is located in the neck under the mandible. The vertebral column contains 26 bones, and it surrounds and protects the spinal cord. The thoracic cage consists of the sternum, ribs, thoracic vertebrae, and costal cartilages. The appendicular skeleton is made up of the limbs of the upper and lower limbs. The pectoral girdle is composed of the clavicles and the scapulae. The upper limb contains 30 bones in the arm, the forearm, and the hand. The pelvic girdle attaches the lower limbs to the axial skeleton. The lower limb includes the bones of the thigh, the leg, and the foot.

### 29.2 Bone

Bone, or osseous tissue, is connective tissue that includes specialized cells, mineral salts, and collagen fibers. The human skeleton can be divided into long bones, short bones, flat bones, and irregular bones. Compact bone tissue is composed of osteons and forms the external layer of all bones. Spongy bone tissue is composed of trabeculae and forms the inner part of all bones. Four types of cells compose bony tissue: osteocytes, osteoclasts, osteoprogenitor cells, and osteoblasts. Ossification is the process of bone formation by osteoblasts. Intramembranous ossification is the process of bone development from fibrous membranes. Endochondral ossification is the process of bone development from hyaline cartilage. Long bones lengthen as chondrocytes divide and secrete hyaline cartilage. Osteoblasts replace cartilage with bone. Appositional growth is the increase in the diameter of bones by the addition of bone tissue at the surface of bones. Bone remodeling involves the processes of bone deposition by osteoblasts and bone resorption by osteoclasts. Bone repair occurs in four stages and can take several months.

### 29.3 Joints and Skeletal Movement

The structural classification of joints divides them into bony, fibrous, cartilaginous, and synovial joints. The bones of fibrous joints are held together by fibrous connective tissue; the three types of fibrous joints are sutures, syndesomes, and gomphoses. Cartilaginous joints are joints in which the bones are connected by cartilage; the two types of cartilaginous joints are synchondroses and symphyses. Synovial joints are joints that have a space between the adjoining bones. The functional classification divides joints into three categories: synarthroses, amphiarthroses, and diarthroses. The movement of synovial joints can be classified as one of four different types: gliding, angular, rotational, or special movement. Gliding movements occur as relatively flat bone surfaces move past each other. Angular movements are produced when the angle between the bones of a joint changes. Rotational movement is the movement of a bone as it rotates around its own longitudinal axis. Special movements include inversion, eversion, protraction, retraction, elevation, depression, dorsiflexion, plantar flexion, supination, pronation, and opposition. Synovial joints are also classified into six different categories on the basis of the shape and structure of the joint: planar, hinge, pivot, condyloid, saddle, and ball-and-socket.

### 29.4 Muscle Contraction and Locomotion

The body contains three types of muscle tissue: skeletal muscle, cardiac muscle, and smooth muscle. Skeleton muscle tissue is composed of sarcomeres, the functional units of muscle tissue. Muscle contraction occurs when sarcomeres shorten, as thick and thin filaments slide past each other, which is called the sliding filament model of muscle contraction. ATP provides the energy for cross-bridge formation and filament sliding. Regulatory proteins, such as troponin and tropomyosin, control cross-bridge formation. Excitation–contraction coupling transduces the electrical signal of the neuron, via acetylcholine, to an electrical signal on the muscle membrane, which initiates force production. The number of muscle fibers contracting determines how much force the whole muscle produces.

## REVIEW QUESTIONS

- Which type of skeletal system of animals is formed by the pressure exerted by the aqueous contents of the coelom on surrounding organs?

- a. hydrostatic skeleton
  - b. exoskeleton
  - c. axial skeleton
  - d. appendicular skeleton
- 2.** The skeletal system is necessary to support the body, protect internal organs, and allow movement. Which of the following organisms must shed and then regenerate its skeletal system as it grows?
- a. earthworm
  - b. lobster
  - c. snake
  - d. sea anemone
- 3.** Which of the following is a role of the human vertebral column?
- a. to protect the heart and lungs
  - b. to support the head
  - c. to attach the upper limbs to the axial skeleton
  - d. to permit locomotion
- 4.** Abnormalities of the thoracic cage are relatively rare, but when they exist they can cause disorders. Which of the following would most be at risk if someone had a defective thoracic cage?
- a. middle ear
  - b. brain
  - c. spinal cord
  - d. heart
- 5.** Which type of skeletal system of animals is composed of a hard skeletal layer found on the exterior of the organism?
- a. hydrostatic skeleton
  - b. exoskeleton
  - c. axial skeleton
  - d. appendicular skeleton
- 6.** Which type of organism moves by peristaltic muscle contraction, extending its body in one direction, then shortening and pulling itself along a surface?
- a. ants
  - b. lizards
  - c. sea stars
  - d. sponges
- 7.** Which type of bone is cuboidal in shape and may be found in the wrist and ankle?
- a. sesamoid bones
  - b. sutural bones
  - c. short bones
  - d. flat bones
- 8.** The bones of human skeletons are classified by their shape. How does the structure of sesamoid bones differ from that of short bones?
- a. Sesamoid bones are small and flat, whereas short bones are approximately equal in height and width.
  - b. Sesamoid bones are thin and broad, whereas short bones have a central shaft and two ends.
  - c. Sesamoid bones are small, flat, and irregularly shaped, whereas short bones are cuboidal in shape.
  - d. Sesamoid bones are thin and broad, whereas short bones are small and flat.
- 9.** The cells responsible for bone resorption are\_\_\_\_\_.
- a. osteoclasts
  - b. osteoblasts
  - c. fibroblasts
  - d. osteocytes
- 10.** A patient was diagnosed with low calcium levels in the blood, which affected nervous system and muscle functions. You decide to examine the functioning of various cells composing the patient's bone tissue. Which type of bone cell is most likely dysfunctional?
- a. osteoclasts
  - b. osteoblasts
  - c. osteoprogenitor cells
  - d. osteocytes
- 11.** Which of the following bones or bone structures forms primarily due to endochondral ossification?
- a. skull
  - b. clavicle
  - c. mandible
  - d. femur
- 12.** What outcome might you expect in an individual with premature epiphyseal plate closure?
- a. overly thick bones
  - b. short stature
  - c. tall stature
  - d. overly thin bones
- 13.** Which type of bone has a central shaft and two rounded ends?

- a. flat bones  
 b. irregular bones  
 c. sutural bones  
 d. long bones
- 14.** Synchondroses and symphyses are connected by \_\_\_\_\_.
- fibers
  - synovial fluid
  - cartilage
  - condyloid
- 15.** \_\_\_\_\_ is a characteristic of the synovial fluid.
- Stability
  - Lubrication
  - Minor movement
  - Increase of friction
- 16.** Which of the following is an example of a pivot joint?
- elbow
  - thumb
  - hip
  - the joint of the wrist
- 17.** Synovial joints allow different types of movement. Turning your head to look over your shoulder is an example of \_\_\_\_\_.
- abduction
  - medial rotation
  - lateral rotation
  - adduction
- 18.** Which of the following is a fibrous joint?
- suture
  - planar joint
  - hinge joint
  - pivot joint
- 19.** Joints are classified based on the material composing the joint and the presence or absence of a cavity in the joint. Which of the following are the weakest joints?
- a. synchondrosis  
 b. fibrous  
 c. synovial  
 d. symphyses
- 20.** \_\_\_\_\_ muscles are also called voluntary muscles.
- Cardiac
  - Smooth
  - Striated
  - Skeletal
- 21.** Which of the following best describes a function of smooth muscle tissue?
- It affects the flow of blood and blood pressure
  - It stimulates contraction of the heart
  - It changes your facial expression.
  - It maintains your posture.
- 22.** In relaxed muscle, the myosin binding site on actin is blocked by \_\_\_\_\_.
- ATP
  - tropomyosin
  - the cross-bridge
  - troponin
- 23.** Which of the following statements does not accurately describe muscle contraction?
- During muscle contraction, the sarcomere shortens.
  - During muscle contraction, the thick and thin filaments shorten.
  - During muscle contraction, the H zone shortens.
  - During muscle contraction, the A band does not shorten.
- 24.** The small structures that make up myofibrils are called \_\_\_\_\_.
- sarcolemma
  - myosins
  - myofilaments
  - sarcomeres
- 25.** You discover an unusual new organism in the deep sea and are studying its skeletal system in a laboratory aquarium. The organism appears to have a radial body plan with a center fluid-filled cavity. If you remove fluid from its interior using a syringe, it seems to collapse somewhat. What kind of skeletal system does this organism likely have?
- 26.** You discover the carcass of an unusual new organism on the beach while on vacation. As a scientist, you decide

to chemically analyze the carcass in order to characterize it. The chemical analysis reveals significant amounts of chitin. What other molecule might you also find associated with the skeletal system of this organism?

- a. calcium carbonate
- b. calcium phosphate
- c. hydroxyapatite
- d. magnesium carbonate

**27.** What types of issues related to bone function would you predict for an individual suffering from a genetic lysosomal storage disease?

- a. Individuals may have deformities in the appendicular skeleton and possible phosphate homeostasis issues.
- b. Individual may have skeletal deformities and possible calcium homeostasis issues.
- c. Individuals may have axial skeleton deformities and possible calcium homeostasis issues.
- d. Individual's brain would be more prone to injury and a possible calcium homeostasis issues.

**28.** A world-class pianist gets into a serious car accident. Injuries to which types of bones will most directly interfere with her career as a pianist?

- a. Injuries to carpals, humerus, radius, ulna, clavicle, metacarpals, metatarsals, tarsals and various flat bones like scapulae would cause issues.
- b. Injuries to carpals, humerus, radius, ulna, clavicle, metacarpals, phalanges and various flat bones like scapulae would cause issues.
- c. Injuries to carpals, humerus, radius, ulna, clavicle, metacarpals, femur, tibia and various flat bones like scapulae would cause issues.
- d. Injuries to carpals, humerus, femur, tibia, metatarsals, tarsals, phalanges and various flat bones like scapulae would cause issues.

**29.** What types of issues related to bone development and repair would you expect associated with someone suffering from osteogenesis imperfecta, a genetic disorder most commonly resulting from defects in collagen production and processing?

- a. Bones are abnormally weak, brittle and highly flexible. In severe cases, individuals may have abnormal bone formation as manifested by thicker and longer bones resulting in a taller stature.
- b. Abnormally weak bones prone to breakage and fracturing upon mild trauma would be expected. In severe cases, individuals may have abnormal bone formation as manifested by thicker and longer bones resulting in a taller stature.
- c. Bones are abnormally weak and highly flexible. In severe cases, individuals may have abnormal bone formation as manifested by thinner and/or shorter bones, perhaps resulting in a shorter stature.
- d. Abnormally weak bones prone to breakage and fracturing upon mild trauma would be expected. In severe cases, individuals may have abnormal bone formation as manifested by thinner and/or shorter bones, perhaps resulting in a shorter stature.

**30.** Osteoporosis is a clinical manifestation of an imbalance between bone resorption and bone formation, resulting in weakened bones that easily fracture. How may one design a therapeutic drug targeting specific bone cell type(s) for the treatment of osteoporosis?

- a. A therapeutic drug that inhibits osteoblast activity would be useful. A drug that enhances the bone formation activity of osteoclasts may also be a good strategy.
- b. A therapeutic drug that inhibits osteoclast activity would be useful. One that reduces the activity of osteoblasts may also be a good strategy.
- c. A therapeutic drug that inhibits osteoclast activity would be useful. One that enhances the bone formation activity of osteoblasts may also be a good strategy.
- d. A therapeutic drug that inhibits osteoblast activity would be useful. One that enhances the bone formation activity of osteoclasts may also be a good strategy.

**31.** Why are shoulder dislocations more common than dislocations of the carpal bones in the hand?

- a. The less mobile a joint, the weaker the joint. The shoulder joint allows the greatest range of motion, while carpal bones are more stable.
- b. The less mobile a joint, the weaker the joint. Carpal bones allow the greatest range of motion, while shoulder joints are more stable.
- c. The more mobile a joint, the weaker the joint. Carpal bones allow the greatest range of motion while shoulder joints are more stable.
- d. The more mobile a joint, the weaker the joint. The shoulder joint allows the greatest range of motion while carpal bones are more stable.

**32.** What angular movements occur at the hip joint and knees as you bend down to touch your toes?

- a. Both the hip joint and knees are flexed.
- b. Both the hip joint and knees are extended.
- c. The hip joint is extended and the knees are flexed.
- d. The hip joint is flexed and the knees are extended.

**33.** What is the main structural difference between synovial joints and cartilaginous and fibrous joints?

- a. Synovial joints allow movement while fibrous and cartilaginous joints do not move at all.
- b. Synovial joints do not move at all while fibrous and cartilaginous joints allow movement.
- c. Synovial joints do not have a space between the adjoining bones while fibrous and cartilaginous joints have a joint cavity.
- d. Synovial joints have a space between the adjoining bones while fibrous and cartilaginous joints do not have a joint cavity.

**34.** What do all types of muscle tissue have in common?

- a. Voluntary muscles cannot be consciously controlled, as is the case with cardiac muscles. Involuntary muscles can be controlled by an individual's will, as is the case with skeletal muscles.
- b. Voluntary muscles can be controlled by an individual's will, as is the case with cardiac muscles. Involuntary muscles cannot be consciously controlled, as is the case with skeletal muscles.
- c. Voluntary muscles cannot be consciously controlled, as is the case with the movement of legs while walking. Involuntary muscles can be controlled by an individual's will, as is the case with muscles in the digestive system.
- d. Voluntary muscles can be controlled by an individual's will, as is the case with skeletal muscles. Involuntary muscles cannot be consciously controlled, as is the case with cardiac muscles.

**35.** How would muscle contractions be affected if ATP was completely depleted in a muscle fiber?

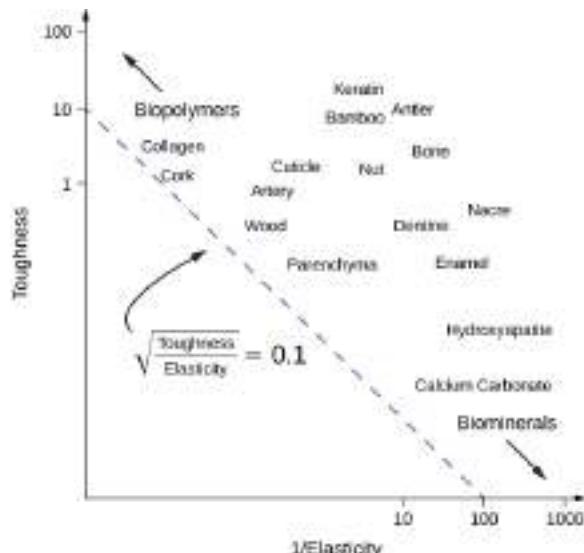

- a. Myosin heads will detach rapidly from the actin-binding sites, resulting in muscle relaxation. In a live person this causes rigor mortis, while in a recently dead person it results in "writer's cramp".
- b. Myosin heads will not detach from the actin-binding sites, resulting in muscle stiffness. In a live person this causes rigor mortis, while in a recently dead person it results in "writer's cramp".
- c. Myosin heads will detach rapidly from the actin-binding sites, resulting in muscle relaxation. In a live person this causes "writer's cramp", while in a recently dead person it results in rigor mortis.
- d. Myosin heads will not detach from the actin-binding sites, resulting in muscle stiffness. In a live person this causes "writer's cramp", while in a recently dead person it results in rigor mortis.

**36.** What is the difference between voluntary and involuntary muscles? Give an example of each.

- Voluntary muscles cannot be consciously controlled, such as cardiac muscles. Involuntary muscles can be controlled by an individual's will, such as skeletal muscles.
- Voluntary muscles can be controlled by an individual's will, such as cardiac muscles. Involuntary muscles cannot be consciously controlled, such as skeletal muscles.
- Voluntary muscles cannot be consciously controlled, such as the movement of legs while walking. Involuntary muscles can be controlled by an individual's will, such as muscles in the digestive system.
- Voluntary muscles can be controlled by an individual's will, such as skeletal muscles. Involuntary muscles cannot be consciously controlled, such as cardiac muscles.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**37.** Biomimetics is the design of engineering solutions guided by biological solutions to similar problems. Support materials in biological systems must be tough, flexible, and light. Engineers define a tough material as one that can absorb energy without fracturing. Flexibility is the ability to deform elastically but able to return to the original shape. Size of in both biological and designed system is often determined by many factors. Density of a material becomes important when size cannot be adjusted but lightness is needed. An analysis of several biological materials in terms of these parameters (Wegst and Ashby, *Philosophical Magazine*, 84, 2004) shows that selection has conserved a bounding value in the product of these parameters; the square root of all of the ratios of toughness and elasticity lie above the dashed line. Patterns like this lead to new science but, in applications to biomimetics, they can also lead to improved technologies.

**Figure 29.39**

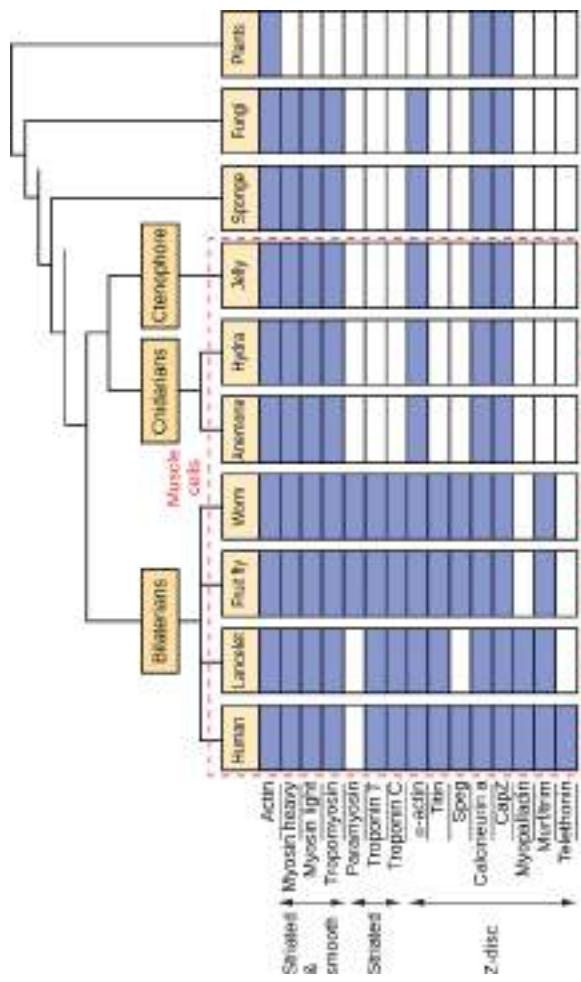

Biopolymers like collagen have higher toughness and higher elasticity. Biominerals like enamel have lower toughness but provide rigidity. Some organisms support soft tissue by combining biopolymers and biomaterials. Some rely more on biopolymers. Note that this is a logarithm scale not a linear scale. So that the difference in toughness of keratin and bone is roughly 100 and the difference in rigidity of these two materials is nearly that large.

A. Use this graph to **pose questions** about the fitness of various biological solutions to the problem of capturing, storing, and using free energy. (Remember that engineers define “toughness” as the ability to absorb energy without fracturing.)

B. **Refine** this representation by identifying an important property of a biomaterial that is missing and explain its importance in terms of free energy acquisition and use.

C. **Explain** how these data indicates that the properties of biopolymers will lead to a better biomimetic design of the humanoid robot than is imagined in C3PO of Star Wars fame

**38.** An investigation of the evolution of muscle was made by Steinmetz et al. (*Nature*, 487, 2012), and a sample of data is presented in the following diagram. Below the accepted phylogeny of major groups are rows with families of genes that code for different muscle proteins, including actin and myosin. Shared genes are shown where the cell is darkened. Samples of genes associated with striated and smooth muscle and the Z-disc that terminates the actin-myosin pair are clustered. These are shown in the diagram below, where groups in which muscle cells occur lie within the box whose edges are dashed lines.

**Figure 29.40**

A. **Analyze** these data in terms of evidence of common ancestry and evidence of the convergent evolution of the muscle cell.

Molecular phylogenetics has provided many insights into the evolution of genes. Because this work is framed by the central organizing principle of evolution it is possible to forget that there are people living today who need evidence that speciation and extinction have occurred throughout Earth's history.

B. Describe in broad outline a plan using molecular databases for either protein or DNA sequences that you could help those who are in need of evidence construct it.

# 30 | THE RESPIRATORY SYSTEM

**Figure 30.1** Lungs, which appear as nearly transparent tissue surrounding the heart in this X-ray of a dog (left), are the central organs of the respiratory system. The left lung is smaller than the right lung to accommodate space for the heart. A dog's nose (right) has a slit on the side of each nostril. When tracking a scent, the slits open, blocking the front of the nostrils. This allows the dog to exhale through the now-open area on the side of the nostrils without losing the scent that is being followed. (credit a: modification of work by Geoff Stearns; credit b: modification of work by Cory Zanker)

## Chapter Outline

- 30.1: Systems of Gas Exchange**
- 30.2: Gas Exchange across Respiratory Surfaces**
- 30.3: Breathing**
- 30.4: Transport of Gases in Human Bodily Fluids**

## Introduction

Breathing is an involuntary event. How often a breath is taken and how much air is inhaled or exhaled are tightly regulated by the respiratory center in the brain. Humans, when they aren't exerting themselves, breathe approximately 15 times per minute on average. Canines, like the dog in **Figure 30.1**, have a respiratory rate of about 15–30 breaths per minute. In addition to exhaling carbon dioxide when we breathe, scientists believe people with cancerous lung cells also exhale tiny amounts of volatile organic compounds. Researchers used specially trained dogs to see if they could tell the difference between people with and without lung cancer. The dogs correctly identified 71 out of 100 lung cancer patients and 372 out of 400 who did not. You can read more about this exciting research [here](http://openstaxcollege.org/l/32lungcancer) (<http://openstaxcollege.org/l/32lungcancer>) .

## 30.1 | Systems of Gas Exchange

In this section, you will explore the following questions:

- How does air pass from the outside environment to the lungs?
- How are lungs protected from particulate matter?

## Connection for AP® Courses

Much of the information in this chapter is not within the scope for AP®. However, studying the respiratory system provides an opportunity to apply concepts we have previously explored, including chemistry and pH, cell membrane structure, and diffusion of molecules across membranes. The respiratory systems of both invertebrate and vertebrate animals—from the tracheal system of insects and gills of fish to lungs in reptiles, birds, and mammals—reflect a distinct pattern of evolution as animals transitioned from aquatic to terrestrial environments. The function of all respiratory systems is to facilitate the exchange of oxygen ( $O_2$ ) and carbon dioxide ( $CO_2$ ) with the environment. Energy production in cellular respiration requires  $O_2$ , and  $CO_2$  is produced as a toxic by-product. Some animals, such as worms and amphibians, use their entire body surface for respiration. Terrestrial animals, including humans, needed a more efficient system for gas exchange. So, take a deep breath (pun intended!) as we take a dive into the activities and functions of the respiratory system.

Do not confuse the respiratory system with cellular respiration although both involve the movement of  $O_2$  and  $CO_2$  (gas exchange) between organism and environment.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 and Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

The primary function of the respiratory system is to deliver oxygen to the cells of the body's tissues and remove carbon dioxide, a cell waste product. The main structures of the human respiratory system are the nasal cavity, the trachea, and lungs.

All aerobic organisms require oxygen to carry out their metabolic functions. Along the evolutionary tree, different organisms have devised different means of obtaining oxygen from the surrounding atmosphere. The environment in which the animal lives greatly determines how an animal respires. The complexity of the respiratory system is correlated with the size of the organism. As animal size increases, diffusion distances increase and the ratio of surface area to volume drops. In unicellular organisms, diffusion across the cell membrane is sufficient for supplying oxygen to the cell (Figure 30.2).

Diffusion is a slow, passive transport process. In order for diffusion to be a feasible means of providing oxygen to the cell, the rate of oxygen uptake must match the rate of diffusion across the membrane. In other words, if the cell were very large or thick, diffusion would not be able to provide oxygen quickly enough to the inside of the cell. Therefore, dependence on diffusion as a means of obtaining oxygen and removing carbon dioxide remains feasible only for small organisms or those with highly-flattened bodies, such as many flatworms (Platyhelminthes). Larger organisms had to evolve specialized respiratory tissues, such as gills, lungs, and respiratory passages accompanied by complex circulatory systems, to transport oxygen throughout their entire body.

**Figure 30.2** The cell of the unicellular algae *Ventricaria ventricosa* is one of the largest known, reaching one to five centimeters in diameter. Like all single-celled organisms, *V. ventricosa* exchanges gases across the cell membrane.

## Direct Diffusion

For small multicellular organisms, diffusion across the outer membrane is sufficient to meet their oxygen needs. Gas exchange by direct diffusion across surface membranes is efficient for organisms less than 1 mm in diameter. In simple organisms, such as cnidarians and flatworms, every cell in the body is close to the external environment. Their cells are kept moist and gases diffuse quickly via direct diffusion. Flatworms are small, literally flat worms, which ‘breathe’ through diffusion across the outer membrane (**Figure 30.3**). The flat shape of these organisms increases the surface area for diffusion, ensuring that each cell within the body is close to the outer membrane surface and has access to oxygen. If the flatworm had a cylindrical body, then the cells in the center would not be able to get oxygen.

**Figure 30.3** This flatworm’s process of respiration works by diffusion across the outer membrane. (credit: Stephen Childs)

## Skin and Gills

Earthworms and amphibians use their skin (integument) as a respiratory organ. A dense network of capillaries lies just below the skin and facilitates gas exchange between the external environment and the circulatory system. The respiratory surface must be kept moist in order for the gases to dissolve and diffuse across cell membranes.

Organisms that live in water need to obtain oxygen from the water. Oxygen dissolves in water but at a lower concentration than in the atmosphere. The atmosphere has roughly 21 percent oxygen. In water, the oxygen concentration is much smaller than that. Fish and many other aquatic organisms have evolved gills to take up the dissolved oxygen from water (**Figure 30.4**). Gills are thin tissue filaments that are highly branched and folded. When water passes over the gills, the dissolved oxygen in water rapidly diffuses across the gills into the bloodstream. The circulatory system can then carry the oxygenated

blood to the other parts of the body. In animals that contain coelomic fluid instead of blood, oxygen diffuses across the gill surfaces into the coelomic fluid. Gills are found in mollusks, annelids, and crustaceans.

**Figure 30.4** This common carp, like many other aquatic organisms, has gills that allow it to obtain oxygen from water. (credit: "Guitardude012"/Wikimedia Commons)

The folded surfaces of the gills provide a large surface area to ensure that the fish gets sufficient oxygen. Diffusion is a process in which material travels from regions of high concentration to low concentration until equilibrium is reached. In this case, blood with a low concentration of oxygen molecules circulates through the gills. The concentration of oxygen molecules in water is higher than the concentration of oxygen molecules in gills. As a result, oxygen molecules diffuse from water (high concentration) to blood (low concentration), as shown in **Figure 30.5**. Similarly, carbon dioxide molecules in the blood diffuse from the blood (high concentration) to water (low concentration).

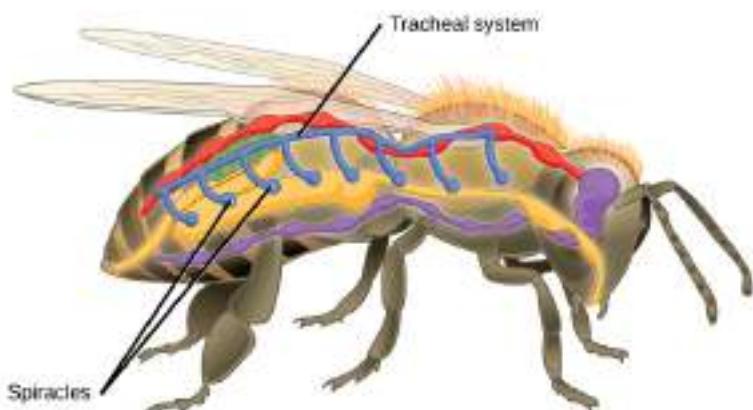

The illustration shows a fish, with a box indicating the location of the gills, behind the head. A close-up image shows the gills, each of which resembles a feathery worm. Two stacks of gills attach to a structure called a columnar gill arch, forming a tall V. Water travels in from the outside of the V, between each gill, then travels out of the top of the V. Veins travel into the gill from the base of the gill arch, and arteries travel back out on the opposite side. A close-up image of a single gill shows that water travels over the gill, passing over deoxygenated veins first, then over oxygenated arteries.

**Figure 30.5** As water flows over the gills, oxygen is transferred to blood via the veins. (credit "fish": modification of work by Duane Raver, NOAA)

## Tracheal Systems

Insect respiration is independent of its circulatory system; therefore, the blood does not play a direct role in oxygen transport. Insects have a highly specialized type of respiratory system called the tracheal system, which consists of a network of small tubes that carries oxygen to the entire body. The tracheal system is the most direct and efficient respiratory system in active animals. The tubes in the tracheal system are made of a polymeric material called chitin.

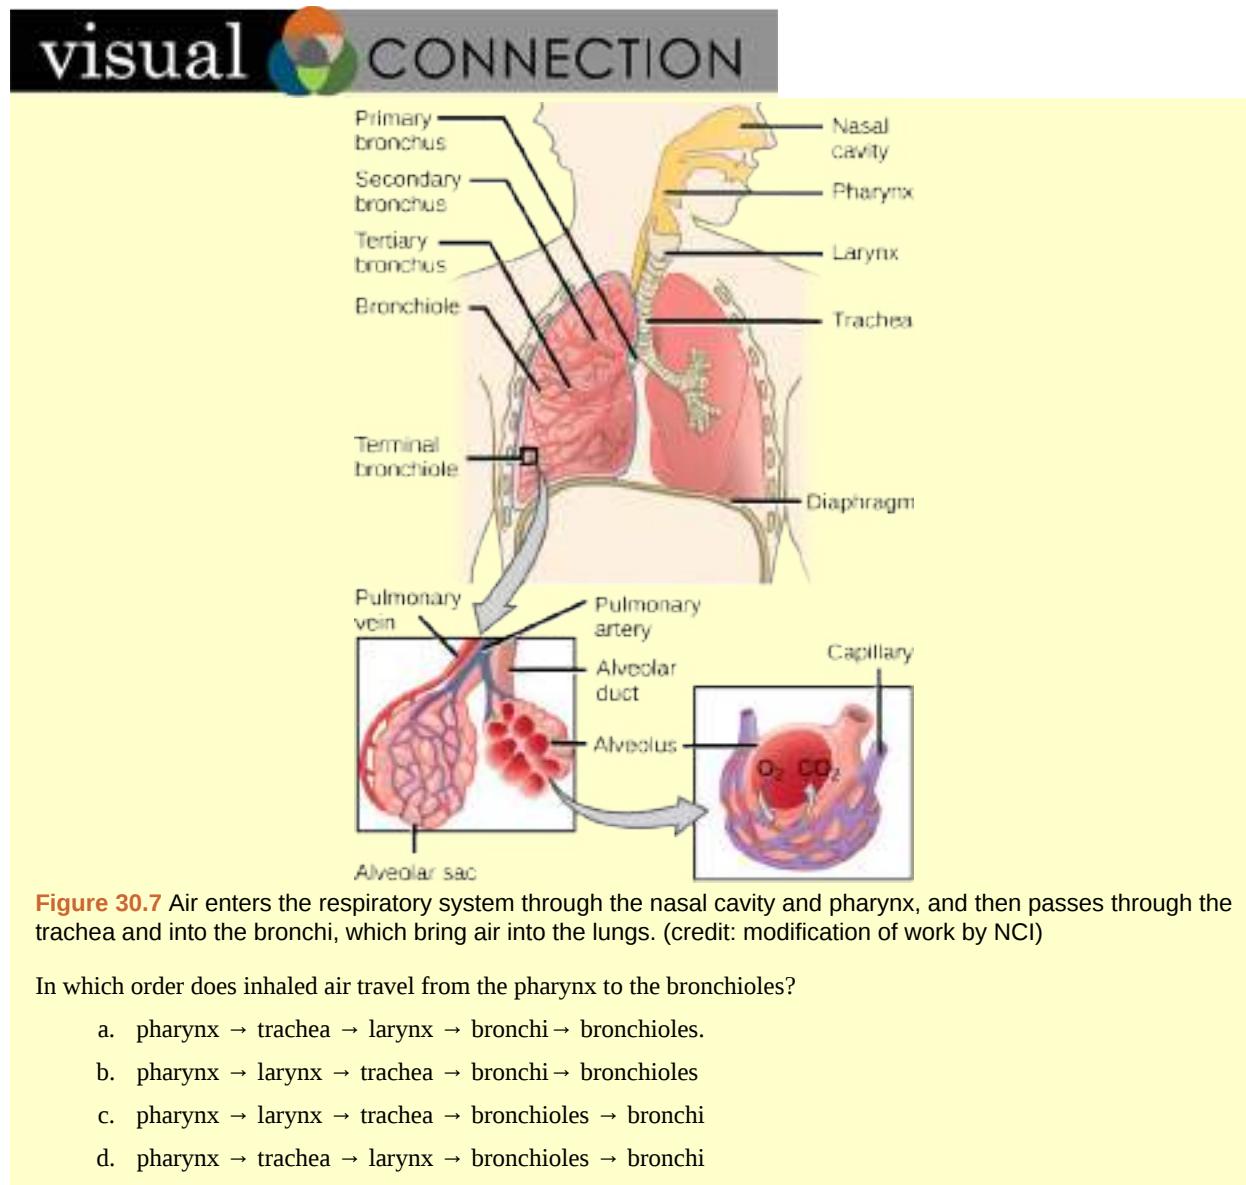

Insect bodies have openings, called spiracles, along the thorax and abdomen. These openings connect to the tubular network, allowing oxygen to pass into the body (**Figure 30.6**) and regulating the diffusion of CO<sub>2</sub> and water vapor. Air enters and leaves the tracheal system through the spiracles. Some insects can ventilate the tracheal system with body movements.

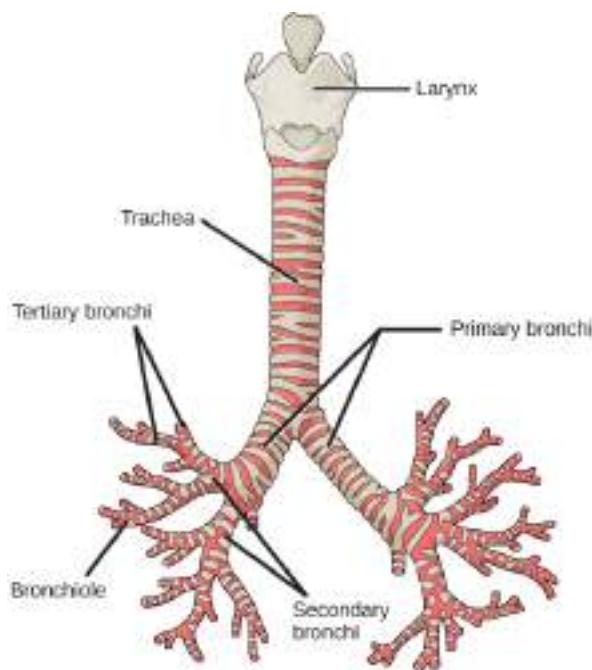

**Figure 30.6** Insects perform respiration via a tracheal system.

## Mammalian Systems

In mammals, pulmonary ventilation occurs via inhalation (breathing). During inhalation, air enters the body through the **nasal cavity** located just inside the nose (**Figure 30.7**). As air passes through the nasal cavity, the air is warmed to body temperature and humidified. The respiratory tract is coated with mucus to seal the tissues from direct contact with air. Mucus is high in water. As air crosses these surfaces of the mucous membranes, it picks up water. These processes help equilibrate the air to the body conditions, reducing any damage that cold, dry air can cause. Particulate matter that is floating in the air is removed in the nasal passages via mucus and cilia. The processes of warming, humidifying, and removing particles are important protective mechanisms that prevent damage to the trachea and lungs. Thus, inhalation serves several purposes in addition to bringing oxygen into the respiratory system.

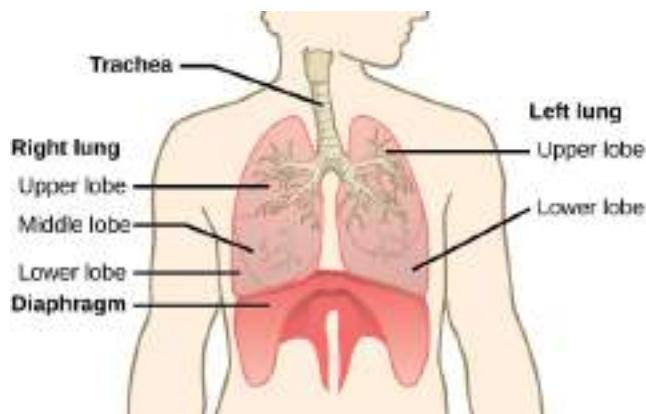

From the nasal cavity, air passes through the **pharynx** (throat) and the **larynx** (voice box), as it makes its way to the **trachea** (Figure 30.7). The main function of the trachea is to funnel the inhaled air to the lungs and the exhaled air back out of the body. The human trachea is a cylinder about 10 to 12 cm long and 2 cm in diameter that sits in front of the esophagus and extends from the larynx into the chest cavity where it divides into the two primary bronchi at the mid thorax. It is made of incomplete rings of hyaline cartilage and smooth muscle (Figure 30.8). The trachea is lined with mucus-producing goblet cells and ciliated epithelia. The cilia propel foreign particles trapped in the mucus toward the pharynx. The cartilage provides strength and support to the trachea to keep the passage open. The smooth muscle can contract, decreasing the trachea's diameter, which causes expired air to rush upwards from the lungs at a great force. The forced exhalation helps expel mucus when we cough. Smooth muscle can contract or relax, depending on stimuli from the external environment or the body's nervous system.

**Figure 30.8** The trachea and bronchi are made of incomplete rings of cartilage. (credit: modification of work by Gray's Anatomy)

### Lungs: Bronchi and Alveoli

The end of the trachea bifurcates (divides) to the right and left lungs. The lungs are not identical. The right lung is larger and contains three lobes, whereas the smaller left lung contains two lobes (**Figure 30.9**). The muscular **diaphragm**, which facilitates breathing, is inferior to (below) the lungs and marks the end of the thoracic cavity.

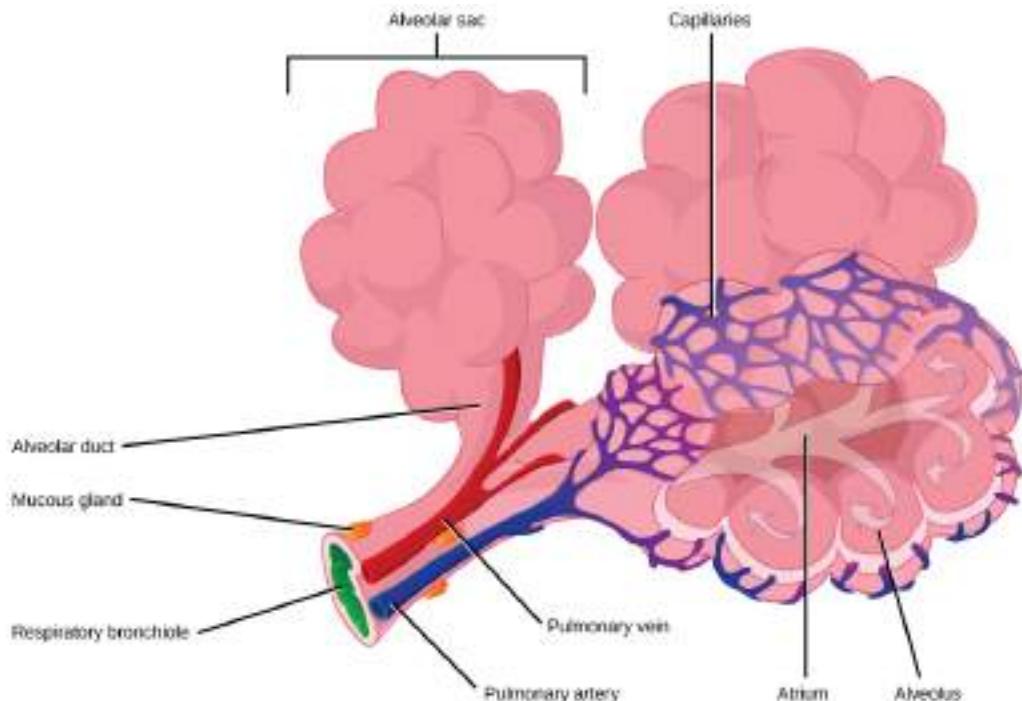

**Figure 30.9** The trachea bifurcates into the right and left bronchi in the lungs. The right lung is made of three lobes and is larger. To accommodate the heart, the left lung is smaller and has only two lobes.

In the lungs, air is diverted into smaller and smaller passages, or **bronchi**. Air enters the lungs through the two **primary (main) bronchi** (singular: bronchus). Each bronchus divides into secondary bronchi, then into tertiary bronchi, which in turn divide, creating smaller and smaller diameter **bronchioles** as they split and spread through the lung. Like the trachea, the bronchi are made of cartilage and smooth muscle. At the bronchioles, the cartilage is replaced with elastic fibers. Bronchi are innervated by nerves of both the parasympathetic and sympathetic nervous systems that control muscle contraction (parasympathetic) or relaxation (sympathetic) in the bronchi and bronchioles, depending on the nervous system's cues. In humans, bronchioles with a diameter smaller than 0.5 mm are the **respiratory bronchioles**. They lack cartilage and therefore rely on inhaled air to support their shape. As the passageways decrease in diameter, the relative amount of smooth muscle increases.

The **terminal bronchioles** subdivide into microscopic branches called respiratory bronchioles. The respiratory bronchioles subdivide into several alveolar ducts. Numerous alveoli and alveolar sacs surround the alveolar ducts. The alveolar sacs resemble bunches of grapes tethered to the end of the bronchioles (**Figure 30.10**). In the acinar region, the **alveolar ducts**

are attached to the end of each bronchiole. At the end of each duct are approximately 100 **alveolar sacs**, each containing 20 to 30 **alveoli** that are 200 to 300 microns in diameter. Gas exchange occurs only in alveoli. Alveoli are made of thin-walled parenchymal cells, typically one-cell thick, that look like tiny bubbles within the sacs. Alveoli are in direct contact with capillaries (one-cell thick) of the circulatory system. Such intimate contact ensures that oxygen will diffuse from alveoli into the blood and be distributed to the cells of the body. In addition, the carbon dioxide that was produced by cells as a waste product will diffuse from the blood into alveoli to be exhaled. The anatomical arrangement of capillaries and alveoli emphasizes the structural and functional relationship of the respiratory and circulatory systems. Because there are so many alveoli (~300 million per lung) within each alveolar sac and so many sacs at the end of each alveolar duct, the lungs have a sponge-like consistency. This organization produces a very large surface area that is available for gas exchange. The surface area of alveoli in the lungs is approximately  $75 \text{ m}^2$ . This large surface area, combined with the thin-walled nature of the alveolar parenchymal cells, allows gases to easily diffuse across the cells.

**Figure 30.10** Terminal bronchioles are connected by respiratory bronchioles to alveolar ducts and alveolar sacs. Each alveolar sac contains 20 to 30 spherical alveoli and has the appearance of a bunch of grapes. Air flows into the atrium of the alveolar sac, then circulates into alveoli where gas exchange occurs with the capillaries. Mucous glands secrete mucus into the airways, keeping them moist and flexible. (credit: modification of work by Mariana Ruiz Villareal)

Watch the following **video** ([http://openstaxcollege.org/l/lungs\\_pulmonary](http://openstaxcollege.org/l/lungs_pulmonary)) to review the respiratory system.

Explain how the structures of the nasal cavity, oral cavity, and pharynx allow one to breathe even when their nostrils are congested due to a cold.

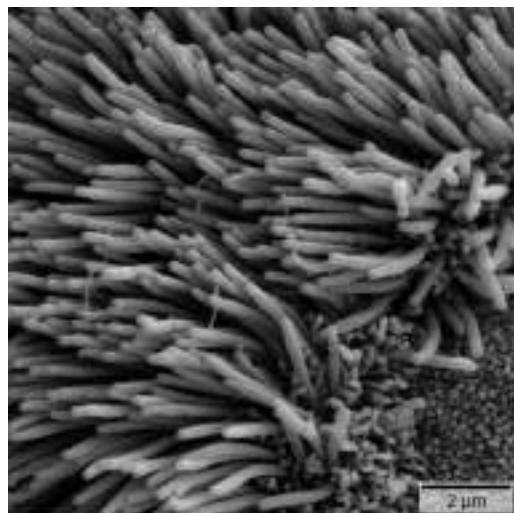

- a. The trachea extends into the nose and mouth.
- b. The pharynx connects the nasal cavity to the lungs, while the larynx connects the oral cavity to the lungs.
- c. The oral and nasal cavities connect to separate lungs.
- d. The nasal and oral cavities combine above the pharynx.

## Protective Mechanisms

The air that organisms breathe contains **particulate matter** such as dust, dirt, viral particles, and bacteria that can damage the lungs or trigger allergic immune responses. The respiratory system contains several protective mechanisms to avoid problems or tissue damage. In the nasal cavity, hairs and mucus trap small particles, viruses, bacteria, dust, and dirt to prevent their entry.

If particulates do make it beyond the nose, or enter through the mouth, the bronchi and bronchioles of the lungs also contain several protective devices. The lungs produce **mucus**—a sticky substance made of **mucin**, a complex glycoprotein, as well as salts and water—that traps particulates. The bronchi and bronchioles contain cilia, small hair-like projections that line the walls of the bronchi and bronchioles (Figure 30.11). These cilia beat in unison and move mucus and particles out of the bronchi and bronchioles back up to the throat where it is swallowed and eliminated via the esophagus.

In humans, for example, tar and other substances in cigarette smoke destroy or paralyze the cilia, making the removal of particles more difficult. In addition, smoking causes the lungs to produce more mucus, which the damaged cilia are not able to move. This causes a persistent cough, as the lungs try to rid themselves of particulate matter, and makes smokers more susceptible to respiratory ailments.

**Figure 30.11** The bronchi and bronchioles contain cilia that help move mucus and other particles out of the lungs. (credit: Louisa Howard, modification of work by Dartmouth Electron Microscope Facility)

### Think About It

How does the structure of alveoli maximize gas exchange?

## 30.2 | Gas Exchange across Respiratory Surfaces

In this section, you will explore the following questions:

- What are the names and descriptions of lung volumes and capacities?
- How does gas pressure influence the movement of gases into and out of the body?

### Connection for AP® Courses

The information in this section about lung volumes and capacities is outside the scope for AP®. However, the content about the movement of gases across the membranes of alveoli is an important application of the principles of diffusion that we explored in the chapter on passive transport. In addition, gas exchange provides the oxygen needed for aerobic cellular respiration and for the removal of carbon dioxide produced as a metabolic waste product.

Gas movement into or out of the lungs is dependent on the pressure of the gas. Because the air we breathe is a mixture of several gases, including N<sub>2</sub>, O<sub>2</sub> and CO<sub>2</sub>, the amount of each gas is measured by its partial pressure. As you remember from our earlier exploration of diffusion, molecules move from an area of higher concentration to lower concentration, or, in the case of gases, from higher partial pressure (measured in mmHg) to lower partial pressure. In other words, O<sub>2</sub> and CO<sub>2</sub> move with their concentration gradients. Because both gases are small, nonpolar molecules, they freely travel across the phospholipid bilayer of the plasma cell membrane.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>2.12</b> The student is able to use representations and models to analyze situations or solve problems qualitatively and quantitatively to investigate whether dynamic homeostasis is maintained by the movement of molecules across membranes. |

The structure of the lung maximizes its surface area to increase gas diffusion. Because of the enormous number of alveoli (approximately 300 million in each human lung), the surface area of the lung is very large ( $75 \text{ m}^2$ ). Having such a large surface area increases the amount of gas that can diffuse into and out of the lungs.

## Basic Principles of Gas Exchange

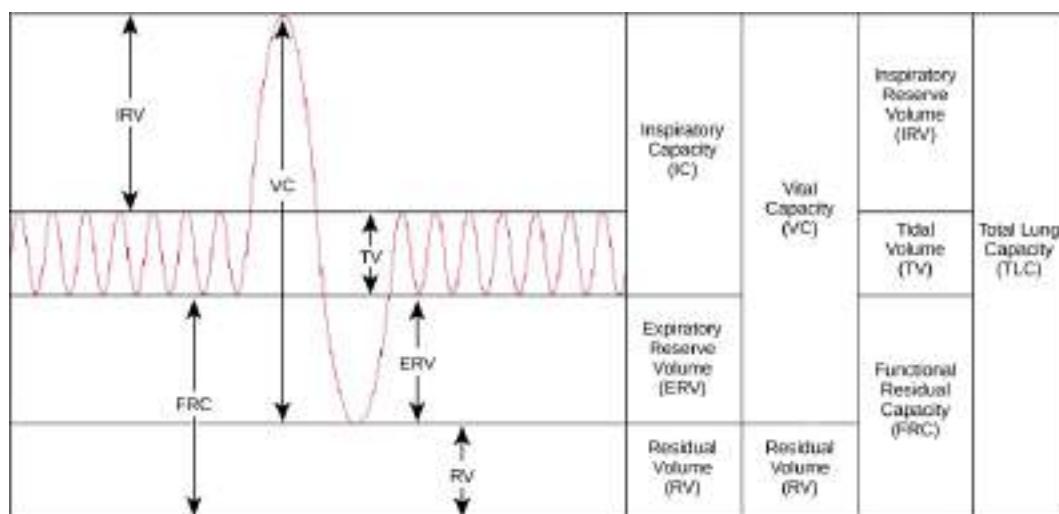

Gas exchange during respiration occurs primarily through diffusion. Diffusion is a process in which transport is driven by a concentration gradient. Gas molecules move from a region of high concentration to a region of low concentration. Blood that is low in oxygen concentration and high in carbon dioxide concentration undergoes gas exchange with air in the lungs. The air in the lungs has a higher concentration of oxygen than that of oxygen-depleted blood and a lower concentration of carbon dioxide. This concentration gradient allows for gas exchange during respiration.

**Partial pressure** is a measure of the concentration of the individual components in a mixture of gases. The total pressure exerted by the mixture is the sum of the partial pressures of the components in the mixture. The rate of diffusion of a gas is proportional to its partial pressure within the total gas mixture. This concept is discussed further in detail below.

## Lung Volumes and Capacities

Different animals have different lung capacities based on their activities. Cheetahs have evolved a much higher lung capacity than humans; it helps provide oxygen to all the muscles in the body and allows them to run very fast. Elephants also have a high lung capacity. In this case, it is not because they run fast but because they have a large body and must be able to take up oxygen in accordance with their body size.

Human lung size is determined by genetics, sex, and height. At maximal capacity, an average lung can hold almost six liters of air, but lungs do not usually operate at maximal capacity. Air in the lungs is measured in terms of **lung volumes** and **lung capacities** (Figure 30.12 and Table 30.1). Volume measures the amount of air for one function (such as inhalation or exhalation). Capacity is any two or more volumes (for example, how much can be inhaled from the end of a maximal exhalation).

**Figure 30.12** Human lung volumes and capacities are shown. The total lung capacity of the adult male is six liters. Tidal volume is the volume of air inhaled in a single, normal breath. Inspiratory capacity is the amount of air taken in during a deep breath, and residual volume is the amount of air left in the lungs after forceful respiration.

### Lung Volumes and Capacities (Avg Adult Male)

| Volume/Capacity                 | Definition                                                  | Volume (liters) | Equations |
|---------------------------------|-------------------------------------------------------------|-----------------|-----------|
| Tidal volume (TV)               | Amount of air inhaled during a normal breath                | 0.5             | -         |
| Expiratory reserve volume (ERV) | Amount of air that can be exhaled after a normal exhalation | 1.2             | -         |

**Table 30.1**

## Lung Volumes and Capacities (Avg Adult Male)

| Volume/<br>Capacity                | Definition                                                                                   | Volume<br>(liters) | Equations     |
|------------------------------------|----------------------------------------------------------------------------------------------|--------------------|---------------|
| Inspiratory reserve volume (IRV)   | Amount of air that can be further inhaled after a normal inhalation                          | 3.1                | -             |
| Residual volume (RV)               | Air left in the lungs after a forced exhalation                                              | 1.2                | -             |
| Vital capacity (VC)                | Maximum amount of air that can be moved in or out of the lungs in a single respiratory cycle | 4.8                | ERV+TV+IRV    |
| Inspiratory capacity (IC)          | Volume of air that can be inhaled in addition to a normal exhalation                         | 3.6                | TV+IRV        |
| Functional residual capacity (FRC) | Volume of air remaining after a normal exhalation                                            | 2.4                | ERV+RV        |
| Total lung capacity (TLC)          | Total volume of air in the lungs after a maximal inspiration                                 | 6.0                | RV+ERV+TV+IRV |
| Forced expiratory volume (FEV1)    | How much air can be forced out of the lungs over a specific time period, usually one second  | ~4.1 to 5.5        | -             |

**Table 30.1**

The volume in the lung can be divided into four units: tidal volume, expiratory reserve volume, inspiratory reserve volume, and residual volume. **Tidal volume (TV)** measures the amount of air that is inspired and expired during a normal breath. On average, this volume is around one-half liter, which is a little less than the capacity of a 20-ounce drink bottle. The **expiratory reserve volume (ERV)** is the additional amount of air that can be exhaled after a normal exhalation. It is the reserve amount that can be exhaled beyond what is normal. Conversely, the **inspiratory reserve volume (IRV)** is the additional amount of air that can be inhaled after a normal inhalation. The **residual volume (RV)** is the amount of air that is left after expiratory reserve volume is exhaled. The lungs are never completely empty: There is always some air left in the lungs after a maximal exhalation. If this residual volume did not exist and the lungs emptied completely, the lung tissues would stick together and the energy necessary to re-inflate the lung could be too great to overcome. Therefore, there is always some air remaining in the lungs. Residual volume is also important for preventing large fluctuations in respiratory gases ( $O_2$  and  $CO_2$ ). The residual volume is the only lung volume that cannot be measured directly because it is impossible to completely empty the lung of air. This volume can only be calculated rather than measured.

Capacities are measurements of two or more volumes. The **vital capacity (VC)** measures the maximum amount of air that can be inhaled or exhaled during a respiratory cycle. It is the sum of the expiratory reserve volume, tidal volume, and inspiratory reserve volume. The **inspiratory capacity (IC)** is the amount of air that can be inhaled after the end of a normal expiration. It is, therefore, the sum of the tidal volume and inspiratory reserve volume. The **functional residual capacity (FRC)** includes the expiratory reserve volume and the residual volume. The FRC measures the amount of additional air that can be exhaled after a normal exhalation. Lastly, the **total lung capacity (TLC)** is a measurement of the total amount of air that the lung can hold. It is the sum of the residual volume, expiratory reserve volume, tidal volume, and inspiratory reserve volume.

Lung volumes are measured by a technique called **spirometry**. An important measurement taken during spirometry is the **forced expiratory volume (FEV)**, which measures how much air can be forced out of the lung over a specific period, usually one second (FEV1). In addition, the forced vital capacity (FVC), which is the total amount of air that can be forcibly exhaled, is measured. The ratio of these values (**FEV1/FVC ratio**) is used to diagnose lung diseases including asthma, emphysema, and fibrosis. If the FEV1/FVC ratio is high, the lungs are not compliant (meaning they are stiff and unable to bend properly), and the patient most likely has lung fibrosis. Patients exhale most of the lung volume very quickly. Conversely, when the FEV1/FVC ratio is low, there is resistance in the lung that is characteristic of asthma. In this instance, it is hard for the patient to get the air out of his or her lungs, and it takes a long time to reach the maximal exhalation volume. In either case, breathing is difficult and complications arise.

 **Career CONNECTION**

## Respiratory Therapist

Respiratory therapists or respiratory practitioners evaluate and treat patients with lung and cardiovascular diseases. They work as part of a medical team to develop treatment plans for patients. Respiratory therapists may treat premature babies with underdeveloped lungs, patients with chronic conditions such as asthma, or older patients suffering from lung disease such as emphysema and chronic obstructive pulmonary disease (COPD). They may operate advanced equipment such as compressed gas delivery systems, ventilators, blood gas analyzers, and resuscitators. Specialized programs to become a respiratory therapist generally lead to a bachelor's degree with a respiratory therapist specialty. Because of a growing aging population, career opportunities as a respiratory therapist are expected to remain strong.

## Gas Pressure and Respiration

The respiratory process can be better understood by examining the properties of gases. Gases move freely, but gas particles are constantly hitting the walls of their vessel, thereby producing gas pressure.

Air is a mixture of gases, primarily nitrogen ( $N_2$ ; 78.6 percent), oxygen ( $O_2$ ; 20.9 percent), water vapor ( $H_2O$ ; 0.5 percent), and carbon dioxide ( $CO_2$ ; 0.04 percent). Each gas component of that mixture exerts a pressure. The pressure for an individual gas in the mixture is the partial pressure of that gas. Approximately 21 percent of atmospheric gas is oxygen. Carbon dioxide, however, is found in relatively small amounts, 0.04 percent. The partial pressure for oxygen is much greater than that of carbon dioxide. The partial pressure of any gas can be calculated by:

$$P = (P_{atm}) \times (\text{percent content in mixture}).$$

$P_{atm}$ , the atmospheric pressure, is the sum of all of the partial pressures of the atmospheric gases added together,

$$P_{atm} = P_{N_2} + P_{O_2} + P_{H_2O} + P_{CO_2} = 760 \text{ mm Hg}$$

$\times$  (percent content in mixture).

The pressure of the atmosphere at sea level is 760 mm Hg. Therefore, the partial pressure of oxygen is:

$$P_{O_2} = (760 \text{ mm Hg}) (0.21) = 160 \text{ mm Hg}$$

and for carbon dioxide:

$$P_{CO_2} = (760 \text{ mm Hg}) (0.0004) = 0.3 \text{ mm Hg}.$$

At high altitudes,  $P_{atm}$  decreases but concentration does not change; the partial pressure decrease is due to the reduction in  $P_{atm}$ .

When the air mixture reaches the lung, it has been humidified. The pressure of the water vapor in the lung does not change the pressure of the air, but it must be included in the partial pressure equation. For this calculation, the water pressure (47 mm Hg) is subtracted from the atmospheric pressure:

$$760 \text{ mm Hg} - 47 \text{ mm Hg} = 713 \text{ mm Hg}$$

and the partial pressure of oxygen is:

$$(760 \text{ mm Hg} - 47 \text{ mm Hg}) \times 0.21 = 150 \text{ mm Hg}.$$

These pressures determine the gas exchange, or the flow of gas, in the system. Oxygen and carbon dioxide will flow according to their pressure gradient from high to low. Therefore, understanding the partial pressure of each gas will aid in understanding how gases move in the respiratory system.

## Gas Exchange across the Alveoli

In the body, oxygen is used by cells of the body's tissues and carbon dioxide is produced as a waste product. The ratio of carbon dioxide production to oxygen consumption is the **respiratory quotient (RQ)**. RQ varies between 0.7 and 1.0. If just glucose were used to fuel the body, the RQ would equal one. One mole of carbon dioxide would be produced for every mole of oxygen consumed. Glucose, however, is not the only fuel for the body. Protein and fat are also used as fuels for the body.

Because of this, less carbon dioxide is produced than oxygen is consumed and the RQ is, on average, about 0.7 for fat and about 0.8 for protein.

The RQ is used to calculate the partial pressure of oxygen in the alveolar spaces within the lung, the **alveolar  $P_{O_2}$** . Above, the partial pressure of oxygen in the lungs was calculated to be 150 mm Hg. However, lungs never fully deflate with an exhalation; therefore, the inspired air mixes with this residual air and lowers the partial pressure of oxygen within the alveoli. This means that there is a lower concentration of oxygen in the lungs than is found in the air outside the body. Knowing the RQ, the partial pressure of oxygen in the alveoli can be calculated:

$$\text{alveolar } P_{O_2} = \text{inspired } P_{O_2} - \left( \frac{\text{alveolar } P_{O_2}}{\text{RQ}} \right)$$

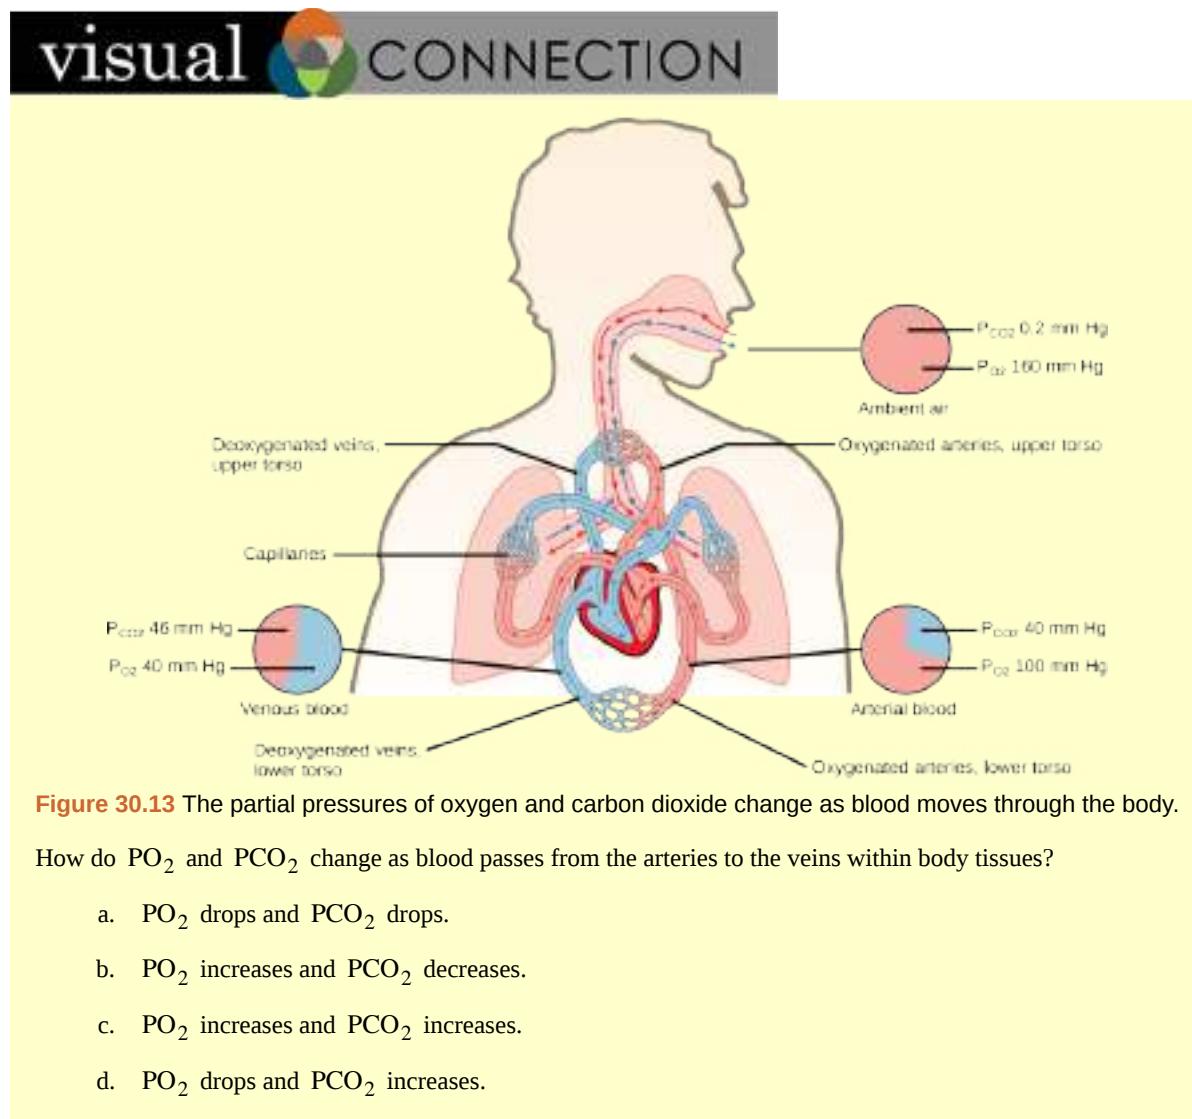

With an RQ of 0.8 and a  $P_{CO_2}$  in the alveoli of 40 mm Hg, the alveolar  $P_{O_2}$  is equal to:

$$\text{alveolar } P_{O_2} = 150 \text{ mm Hg} - \left( \frac{40 \text{ mm Hg}}{0.8} \right) = \text{mm Hg.}$$

Notice that this pressure is less than the external air. Therefore, the oxygen will flow from the inspired air in the lung ( $P_{O_2} = 150 \text{ mm Hg}$ ) into the bloodstream ( $P_{O_2} = 100 \text{ mm Hg}$ ) (Figure 30.13).

In the lungs, oxygen diffuses out of the alveoli and into the capillaries surrounding the alveoli. Oxygen (about 98 percent) binds reversibly to the respiratory pigment hemoglobin found in red blood cells (RBCs). RBCs carry oxygen to the tissues where oxygen dissociates from the hemoglobin and diffuses into the cells of the tissues. More specifically, alveolar  $P_{O_2}$  is higher in the alveoli ( $P_{ALVO_2} = 100 \text{ mm Hg}$ ) than blood  $P_{O_2}$  (40 mm Hg) in the capillaries. Because this pressure gradient exists, oxygen diffuses down its pressure gradient, moving out of the alveoli and entering the blood of the capillaries where  $O_2$  binds to hemoglobin. At the same time, alveolar  $P_{CO_2}$  is lower  $P_{ALVO_2} = 40 \text{ mm Hg}$  than blood  $P_{CO_2} = (45 \text{ mm Hg})$ .  $CO_2$  diffuses down its pressure gradient, moving out of the capillaries and entering the alveoli.

Oxygen and carbon dioxide move independently of each other; they diffuse down their own pressure gradients. As blood leaves the lungs through the pulmonary veins, the **venous  $P_{O_2}$**  = 100 mm Hg, whereas the **venous  $P_{CO_2}$**  = 40 mm Hg. As blood enters the systemic capillaries, the blood will lose oxygen and gain carbon dioxide because of the pressure difference of the tissues and blood. In systemic capillaries,  $P_{O_2} = 100 \text{ mm Hg}$ , but in the tissue cells,  $P_{O_2} = 40 \text{ mm Hg}$ . This pressure gradient drives the diffusion of oxygen out of the capillaries and into the tissue cells. At the same time, blood  $P_{CO_2} = 40 \text{ mm Hg}$  and systemic tissue  $P_{CO_2} = 45 \text{ mm Hg}$ . The pressure gradient drives  $CO_2$  out of tissue cells and into the capillaries. The blood returning to the lungs through the pulmonary arteries has a venous  $P_{O_2} = 40 \text{ mm Hg}$  and a  $P_{CO_2} = 45 \text{ mm Hg}$ . The blood enters the lung capillaries where the process of exchanging gases between the capillaries and alveoli begins again (Figure 30.13).

In short, the change in partial pressure from the alveoli to the capillaries drives the oxygen into the tissues and the carbon dioxide into the blood from the tissues. The blood is then transported to the lungs where differences in pressure in the alveoli result in the movement of carbon dioxide out of the blood into the lungs, and oxygen into the blood.

Watch this **video** (<http://openstaxcollege.org/l/spirometry>) to learn how to carry out spirometry.

What kinds of injuries or disease could spirometry best detect?

- a. infections of the trachea, larynx or pharynx
- b. a decrease in the capacity of the lungs to hold air
- c. mucus buildup in the nasal cavities
- d. a reduction in alveoli in the lungs

## science practices CONNECTION for AP<sup>®</sup> Courses

### Think About It

How can a respiratory infection such as pneumonia affect the exchange of gases between the alveoli in the lungs and the capillaries surrounding them?

## 30.3 | Breathing

In this section, you will explore the following questions:

- How do the structure of the lungs and thoracic cavity control the mechanics of breathing?
- What is the importance of compliance and resistance in the lungs?

### Connection for AP<sup>®</sup> Courses

The information in this section is not within the scope for AP<sup>®</sup> and does not align to the Curriculum Framework. However, understanding how breathing occurs enhances ones understanding of the structure and function of the respiratory system.

Mammalian lungs are located in the thoracic cavity where they are surrounded and protected by the rib cage, intercostal muscles, and bound by the chest wall. The bottom of the lungs is contained by the diaphragm, a skeletal muscle that facilitates breathing. Breathing requires the coordination of the lungs, the chest wall, and most importantly, the diaphragm.

### Types of Breathing

Amphibians have evolved multiple ways of breathing. Young amphibians, like tadpoles, use gills to breathe, and they don't leave the water. Some amphibians retain gills for life. As the tadpole grows, the gills disappear and lungs grow. These lungs are primitive and not as evolved as mammalian lungs. Adult amphibians are lacking or have a reduced diaphragm, so breathing via lungs is forced. The other means of breathing for amphibians is diffusion across the skin. To aid this diffusion, amphibian skin must remain moist.

Birds face a unique challenge with respect to breathing: They fly. Flying consumes a great amount of energy; therefore, birds require a lot of oxygen to aid their metabolic processes. Birds have evolved a respiratory system that supplies them with

the oxygen needed to enable flying. Similar to mammals, birds have lungs, which are organs specialized for gas exchange. Oxygenated air, taken in during inhalation, diffuses across the surface of the lungs into the bloodstream, and carbon dioxide diffuses from the blood into the lungs and expelled during exhalation. The details of breathing between birds and mammals differ substantially.

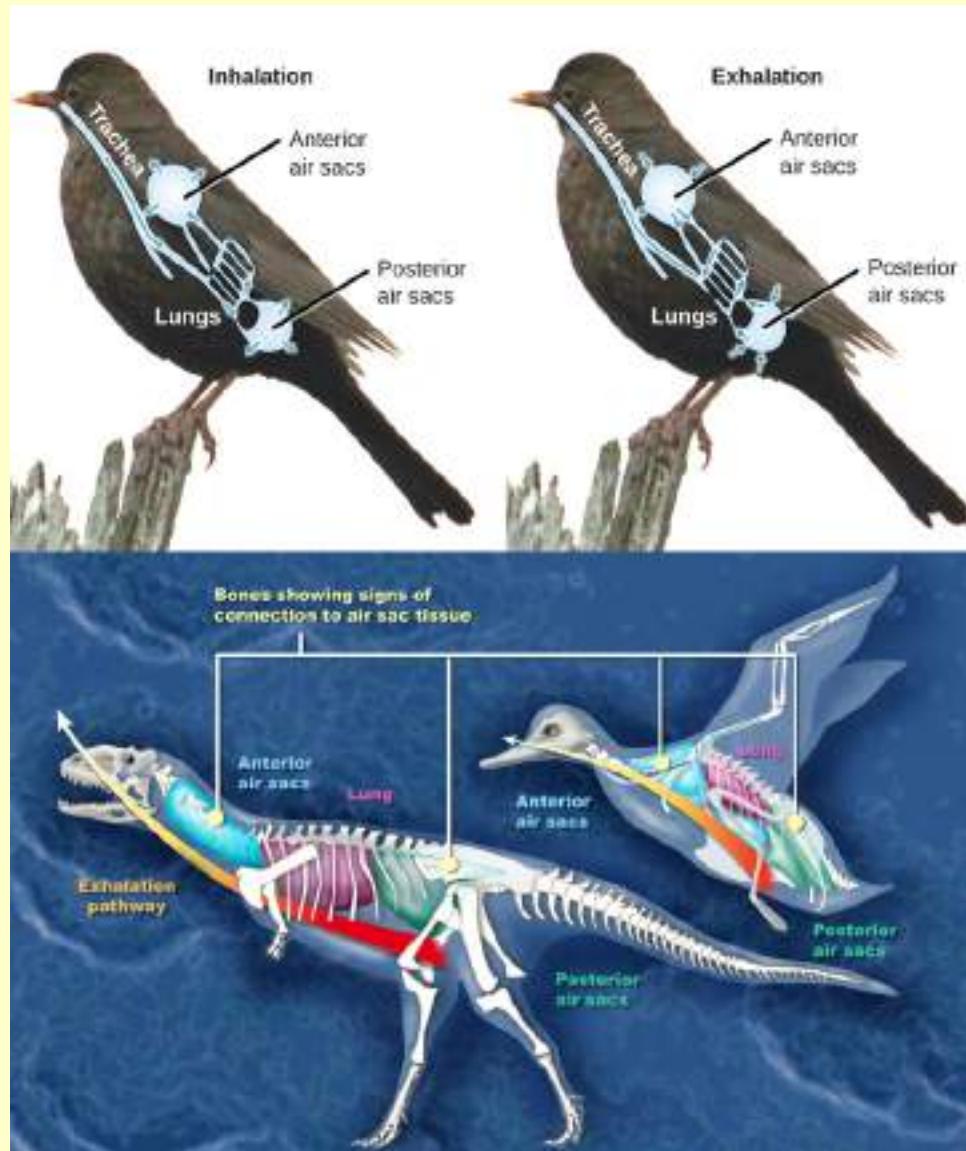

In addition to lungs, birds have air sacs inside their body. Air flows in one direction from the posterior air sacs to the lungs and out of the anterior air sacs. The flow of air is in the opposite direction from blood flow, and gas exchange takes place much more efficiently. This type of breathing enables birds to obtain the requisite oxygen, even at higher altitudes where the oxygen concentration is low. This directionality of airflow requires two cycles of air intake and exhalation to completely get the air out of the lungs.

# evolution CONNECTION

## Avian Respiration

Birds have evolved a respiratory system that enables them to fly. Flying is a high-energy process and requires a lot of oxygen. Furthermore, many birds fly in high altitudes where the concentration of oxygen is low. How did birds evolve a respiratory system that is so unique?

Decades of research by paleontologists have shown that birds evolved from theropods, meat-eating dinosaurs (Figure 30.14). In fact, fossil evidence shows that meat-eating dinosaurs that lived more than 100 million years ago had a similar flow-through respiratory system with lungs and air sacs. *Archaeopteryx* and *Xiaotingia*, for example, were flying dinosaurs and are believed to be early precursors of birds.

**Figure 30.14** (a) Birds have a flow-through respiratory system in which air flows unidirectionally from the posterior sacs into the lungs, then into the anterior air sacs. The air sacs connect to openings in hollow bones. (b) Dinosaurs, from which birds descended, have similar hollow bones and are believed to have had a similar respiratory system. (credit b: modification of work by Zina Deretsky, National Science Foundation)

Most of us consider that dinosaurs are extinct. However, modern birds are descendants of avian dinosaurs. The respiratory system of modern birds has been evolving for hundreds of millions of years.

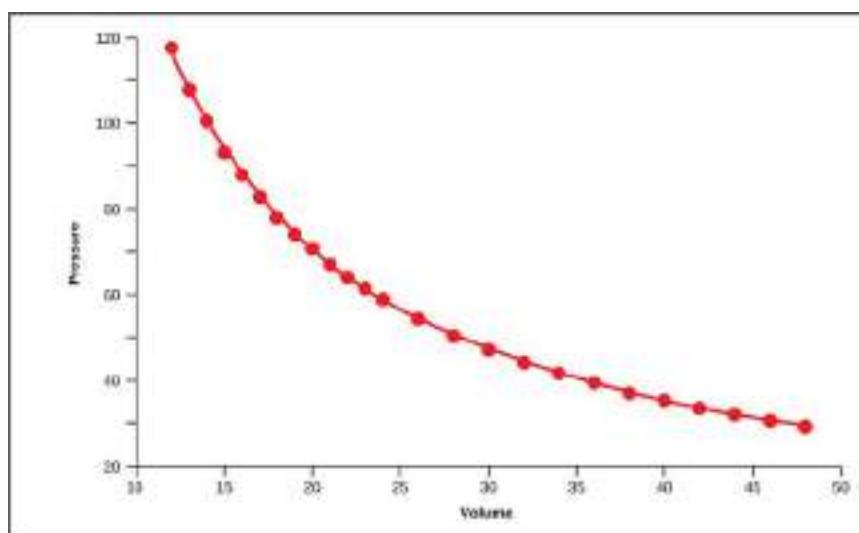

Recall the exhalation pathway of birds. What is meant by the statement, “these animals have a ‘flow-through respiratory system,’” and how does this aid in flight?

- a. The “flow-through respiratory system” allows air to only entirely in one direction, without retracing its pathway at all, allowing the animal to breathe faster while in flight
- b. The “flow-through respiratory system” contains several air sacs that make the animal lighter compared to similar-sized animals with no air sacs.
- c. The “flow-through respiratory system” contains many lungs, which allow the animals to take in the large quantities of oxygen needed for flight.
- d. The “flow-through respiratory system” allows air to move in an almost unidirectional pathway to reach a series of air sacs that provide air to hollow bones, making the animals lighter and providing efficient respiration.

All mammals have lungs that are the main organs for breathing. Lung capacity has evolved to support the animal’s activities. During inhalation, the lungs expand with air, and oxygen diffuses across the lung’s surface and enters the bloodstream. During exhalation, the lungs expel air and lung volume decreases. In the next few sections, the process of human breathing will be explained.

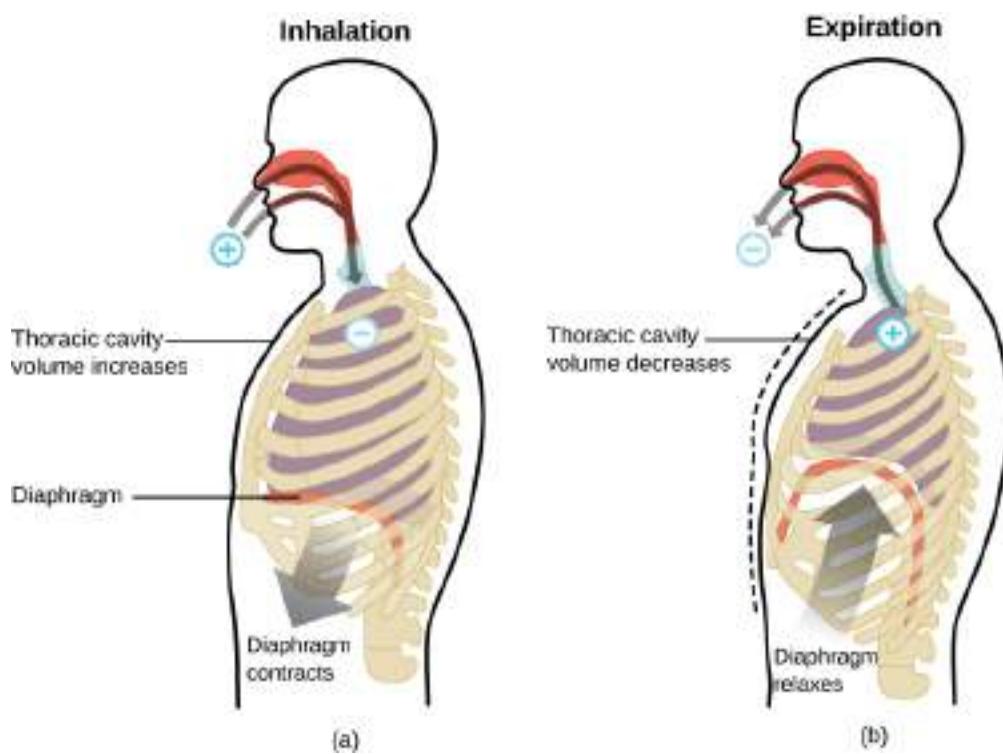

## The Mechanics of Human Breathing

Boyle’s Law is the gas law that states that in a closed space, pressure and volume are inversely related. As volume decreases, pressure increases and vice versa (Figure 30.15). The relationship between gas pressure and volume helps to explain the mechanics of breathing.

**Figure 30.15** This graph shows data from Boyle’s original 1662 experiment, which shows that pressure and volume are inversely related. No units are given as Boyle used arbitrary units in his experiments.

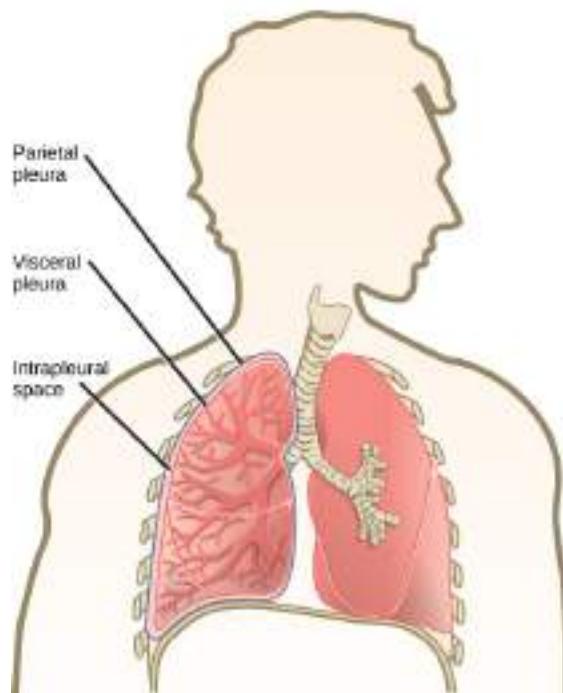

There is always a slightly negative pressure within the thoracic cavity, which aids in keeping the airways of the lungs open. During inhalation, volume increases as a result of contraction of the diaphragm, and pressure decreases (according to Boyle’s Law). This decrease of pressure in the thoracic cavity relative to the environment makes the cavity less than the atmosphere (Figure 30.16a). Because of this drop in pressure, air rushes into the respiratory passages. To increase the volume of the lungs, the chest wall expands. This results from the contraction of the **intercostal muscles**, the muscles that are connected to the rib cage. Lung volume expands because the diaphragm contracts and the intercostals muscles contract, thus expanding the thoracic cavity. This increase in the volume of the thoracic cavity lowers pressure compared to the atmosphere, so air rushes into the lungs, thus increasing its volume. The resulting increase in volume is largely attributed to an increase in alveolar space, because the bronchioles and bronchi are stiff structures that do not change in size.

**Figure 30.16** The lungs, chest wall, and diaphragm are all involved in respiration, both (a) inhalation and (b) expiration.

The chest wall expands out and away from the lungs. The lungs are elastic; therefore, when air fills the lungs, the **elastic recoil** within the tissues of the lung exerts pressure back toward the interior of the lungs. These outward and inward forces compete to inflate and deflate the lung with every breath. Upon exhalation, the lungs recoil to force the air out of the lungs, and the intercostal muscles relax, returning the chest wall back to its original position (Figure 30.16b). The diaphragm also relaxes and moves higher into the thoracic cavity. This increases the pressure within the thoracic cavity relative to the environment, and air rushes out of the lungs. The movement of air out of the lungs is a passive event. No muscles are contracting to expel the air.

Each lung is surrounded by an invaginated sac. The layer of tissue that covers the lung and dips into spaces is called the **visceral pleura**. A second layer of parietal pleura lines the interior of the thorax (Figure 30.17). The space between these layers, the **intrapleural space**, contains a small amount of fluid that protects the tissue and reduces the friction generated from rubbing the tissue layers together as the lungs contract and relax. **Pleurisy** results when these layers of tissue become inflamed; it is painful because the inflammation increases the pressure within the thoracic cavity and reduces the volume of the lung.

**Figure 30.17** A tissue layer called pleura surrounds the lung and interior of the thoracic cavity. (credit: modification of work by NCI)

View ([http://openstaxcollege.org/l/boyle\\_breathing](http://openstaxcollege.org/l/boyle_breathing)) how Boyle's Law is related to breathing and watch **this video** ([http://openstaxcollege.org/l/boyles\\_law](http://openstaxcollege.org/l/boyles_law)) on Boyle's Law.

How does the relationship between the pressure and volume of a gas, as described by Boyle's law, relate to the changes in lung pressure during inhalation and exhalation?

- Boyle's law states the pressure of a gas is directly proportional to its volume. Therefore, the lungs control the volume of air by altering the air pressure of the thoracic cavity.
- Boyle's law states the pressure of a gas is inversely proportional to its volume. Therefore, the lungs control air pressure by altering the volume of the thoracic cavity.
- Boyle's law states the pressure of a gas is inversely proportional to its volume. Therefore, the lungs control air pressure by expanding and pushing out the muscles of the thoracic cavity.
- Boyle's law states the pressure of a gas is directly proportional to its volume. Therefore, the lungs control air pressure by controlling the volume of the thoracic cavity, not vice versa.

## The Work of Breathing

The number of breaths per minute is the **respiratory rate**. On average, under non-exertion conditions, the human respiratory rate is 12–15 breaths/minute. The respiratory rate contributes to the **alveolar ventilation**, or how much air moves into and out of the alveoli. Alveolar ventilation prevents carbon dioxide buildup in the alveoli. There are two ways to keep the alveolar ventilation constant: increase the respiratory rate while decreasing the tidal volume of air per breath (shallow

breathing), or decrease the respiratory rate while increasing the tidal volume per breath. In either case, the ventilation remains the same, but the work done and type of work needed are quite different. Both tidal volume and respiratory rate are closely regulated when oxygen demand increases.

There are two types of work conducted during respiration, flow-resistive and elastic work. **Flow-resistive** refers to the work of the alveoli and tissues in the lung, whereas **elastic work** refers to the work of the intercostal muscles, chest wall, and diaphragm. Increasing the respiration rate increases the flow-resistive work of the airways and decreases the elastic work of the muscles. Decreasing the respiratory rate reverses the type of work required.

### **Surfactant**

The air-tissue/water interface of the alveoli has a high surface tension. This surface tension is similar to the surface tension of water at the liquid-air interface of a water droplet that results in the bonding of the water molecules together. **Surfactant** is a complex mixture of phospholipids and lipoproteins that works to reduce the surface tension that exists between the alveoli tissue and the air found within the alveoli. By lowering the surface tension of the alveolar fluid, it reduces the tendency of alveoli to collapse.

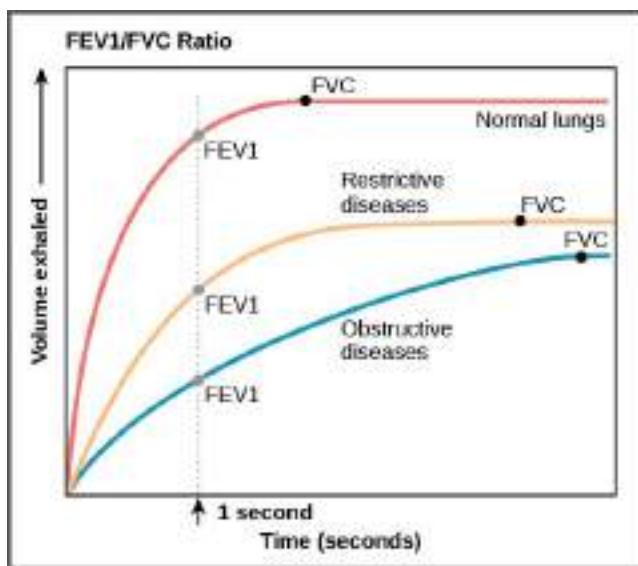

Surfactant works like a detergent to reduce the surface tension and allows for easier inflation of the airways. When a balloon is first inflated, it takes a large amount of effort to stretch the plastic and start to inflate the balloon. If a little bit of detergent was applied to the interior of the balloon, then the amount of effort or work needed to begin to inflate the balloon would decrease, and it would become much easier to start blowing up the balloon. This same principle applies to the airways. A small amount of surfactant to the airway tissues reduces the effort or work needed to inflate those airways. Babies born prematurely sometimes do not produce enough surfactant. As a result, they suffer from **respiratory distress syndrome**, because it requires more effort to inflate their lungs. Surfactant is also important for preventing collapse of small alveoli relative to large alveoli.

### **Lung Resistance and Compliance**

Pulmonary diseases reduce the rate of gas exchange into and out of the lungs. Two main causes of decreased gas exchange are **compliance** (how elastic the lung is) and **resistance** (how much obstruction exists in the airways). A change in either can dramatically alter breathing and the ability to take in oxygen and release carbon dioxide.

Examples of **restrictive diseases** are respiratory distress syndrome and pulmonary fibrosis. In both diseases, the airways are less compliant and they are stiff or fibrotic. There is a decrease in compliance because the lung tissue cannot bend and move. In these types of restrictive diseases, the intrapleural pressure is more positive and the airways collapse upon exhalation, which traps air in the lungs. Forced or **functional vital capacity (FVC)**, which is the amount of air that can be forcibly exhaled after taking the deepest breath possible, is much lower than in normal patients, and the time it takes to exhale most of the air is greatly prolonged ([Figure 30.18](#)). A patient suffering from these diseases cannot exhale the normal amount of air.

**Obstructive diseases** and conditions include emphysema, asthma, and pulmonary edema. In emphysema, which mostly arises from smoking tobacco, the walls of the alveoli are destroyed, decreasing the surface area for gas exchange. The overall compliance of the lungs is increased, because as the alveolar walls are damaged, lung elastic recoil decreases due to a loss of elastic fibers, and more air is trapped in the lungs at the end of exhalation. Asthma is a disease in which inflammation is triggered by environmental factors. Inflammation obstructs the airways. The obstruction may be due to edema (fluid accumulation), smooth muscle spasms in the walls of the bronchioles, increased mucus secretion, damage to the epithelia of the airways, or a combination of these events. Those with asthma or edema experience increased occlusion from increased inflammation of the airways. This tends to block the airways, preventing the proper movement of gases ([Figure 30.18](#)). Those with obstructive diseases have large volumes of air trapped after exhalation and breathe at a very high lung volume to compensate for the lack of airway recruitment.

**Figure 30.18** The ratio of FEV1 (the amount of air that can be forcibly exhaled in one second after taking a deep breath) to FVC (the total amount of air that can be forcibly exhaled) can be used to diagnose whether a person has restrictive or obstructive lung disease. In restrictive lung disease, FVC is reduced but airways are not obstructed, so the person is able to expel air reasonably fast. In obstructive lung disease, airway obstruction results in slow exhalation as well as reduced FVC. Thus, the FEV1/FVC ratio is lower in persons with obstructive lung disease (less than 69 percent) than in persons with restrictive disease (88 to 90 percent).

## Dead Space: V/Q Mismatch

Pulmonary circulation pressure is very low compared to that of the systemic circulation. It is also independent of cardiac output. This is because of a phenomenon called **recruitment**, which is the process of opening airways that normally remain closed when cardiac output increases. As cardiac output increases, the number of capillaries and arteries that are perfused (filled with blood) increases. These capillaries and arteries are not always in use but are ready if needed. At times, however, there is a mismatch between the amount of air (ventilation, V) and the amount of blood (perfusion, Q) in the lungs. This is referred to as **ventilation/perfusion (V/Q) mismatch**.

There are two types of V/Q mismatch. Both produce **dead space**, regions of broken down or blocked lung tissue. Dead spaces can severely impact breathing, because they reduce the surface area available for gas diffusion. As a result, the amount of oxygen in the blood decreases, whereas the carbon dioxide level increases. Dead space is created when no ventilation and/or perfusion takes place. **Anatomical dead space** or anatomical shunt, arises from an anatomical failure, while **physiological dead space** or physiological shunt, arises from a functional impairment of the lung or arteries.

An example of an anatomical shunt is the effect of gravity on the lungs. The lung is particularly susceptible to changes in the magnitude and direction of gravitational forces. When someone is standing or sitting upright, the pleural pressure gradient leads to increased ventilation further down in the lung. As a result, the intrapleural pressure is more negative at the base of the lung than at the top, and more air fills the bottom of the lung than the top. Likewise, it takes less energy to pump blood to the bottom of the lung than to the top when in a prone position. Perfusion of the lung is not uniform while standing or sitting. This is a result of hydrostatic forces combined with the effect of airway pressure. An anatomical shunt develops because the ventilation of the airways does not match the perfusion of the arteries surrounding those airways. As a result, the rate of gas exchange is reduced. Note that this does not occur when lying down, because in this position, gravity does not preferentially pull the bottom of the lung down.

A physiological shunt can develop if there is infection or edema in the lung that obstructs an area. This will decrease ventilation but not affect perfusion; therefore, the V/Q ratio changes and gas exchange is affected.

The lung can compensate for these mismatches in ventilation and perfusion. If ventilation is greater than perfusion, the arterioles dilate and the bronchioles constrict. This increases perfusion and reduces ventilation. Likewise, if ventilation is less than perfusion, the arterioles constrict and the bronchioles dilate to correct the imbalance.

Visit this site (<http://openstaxcollege.org/l/breathing>) to view the mechanics of breathing.

How does the downward movement of the diaphragm allow us to breathe?

- a. It reduces the volume of the thoracic cavity, increasing the air pressure in the lungs and triggering inhalation.
- b. It reduces the volume of the thoracic cavity, increasing the air pressure in the lungs and triggering exhalation.
- c. It creates a partial vacuum in the thoracic cavity into which outside air flows during exhalation.
- d. It creates a partial vacuum in the thoracic cavity into which outside air flows during inhalation.

## 30.4 | Transport of Gases in Human Bodily Fluids

In this section, you will explore the following questions:

- How is oxygen bound to hemoglobin and transported to body tissues?
- How is carbon dioxide transported from body tissues to the lungs?

### Connection for AP® Courses

Gas exchange at the tissue level also occurs by diffusion. The majority of oxygen transported from the lungs to body tissue is bound to a protein called hemoglobin. Hemoglobin is a quaternary protein comprise of four iron-containing heme groups; iron has a great affinity for oxygen. (We know this because iron rusts when exposed to air.)

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Once the oxygen diffuses across the alveoli, it enters the bloodstream and is transported to the tissues where it is unloaded, and carbon dioxide diffuses out of the blood and into the alveoli to be expelled from the body. Although gas exchange is a continuous process, the oxygen and carbon dioxide are transported by different mechanisms.

## Transport of Oxygen in the Blood

Although oxygen dissolves in blood, only a small amount of oxygen is transported this way. Only 1.5 percent of oxygen in the blood is dissolved directly into the blood itself. Most oxygen—98.5 percent—is bound to a protein called hemoglobin and carried to the tissues.

### Hemoglobin

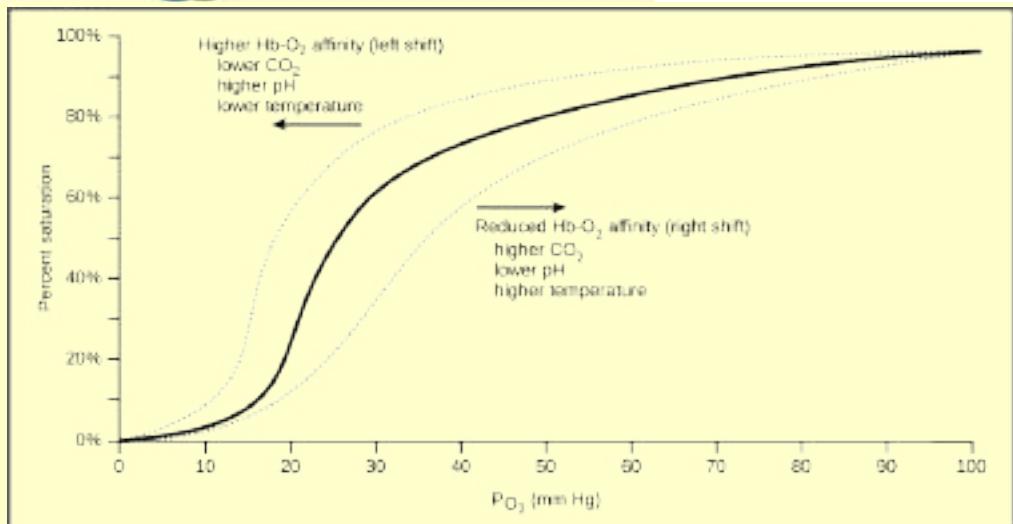

**Hemoglobin**, or Hb, is a protein molecule found in red blood cells (erythrocytes) made of four subunits: two alpha subunits and two beta subunits (Figure 30.19). Each subunit surrounds a central **heme group** that contains iron and binds one oxygen molecule, allowing each hemoglobin molecule to bind four oxygen molecules. Molecules with more oxygen bound to the heme groups are brighter red. As a result, oxygenated arterial blood where the Hb is carrying four oxygen molecules is bright red, while venous blood that is deoxygenated is darker red.

**Figure 30.19** The protein inside (a) red blood cells that carries oxygen to cells and carbon dioxide to the lungs is (b) hemoglobin. Hemoglobin is made up of four symmetrical subunits and four heme groups. Iron associated with the heme binds oxygen. It is the iron in hemoglobin that gives blood its red color.

It is easier to bind a second and third oxygen molecule to Hb than the first molecule. This is because the hemoglobin molecule changes its shape, or conformation, as oxygen binds. The fourth oxygen is then more difficult to bind. The binding of oxygen to hemoglobin can be plotted as a function of the partial pressure of oxygen in the blood (x-axis) versus the relative Hb-oxygen saturation (y-axis). The resulting graph—an **oxygen dissociation curve**—is sigmoidal, or S-shaped (Figure 30.20). As the partial pressure of oxygen increases, the hemoglobin becomes increasingly saturated with oxygen.

# visual CONNECTION

**Figure 30.20** The oxygen dissociation curve demonstrates that, as the partial pressure of oxygen increases, more oxygen binds hemoglobin. However, the affinity of hemoglobin for oxygen may shift to the left or the right depending on environmental conditions.

The kidneys are responsible for removing excess hydrogen ions from the blood. If the kidneys fail, what would happen to blood pH and hemoglobin affinity for oxygen?

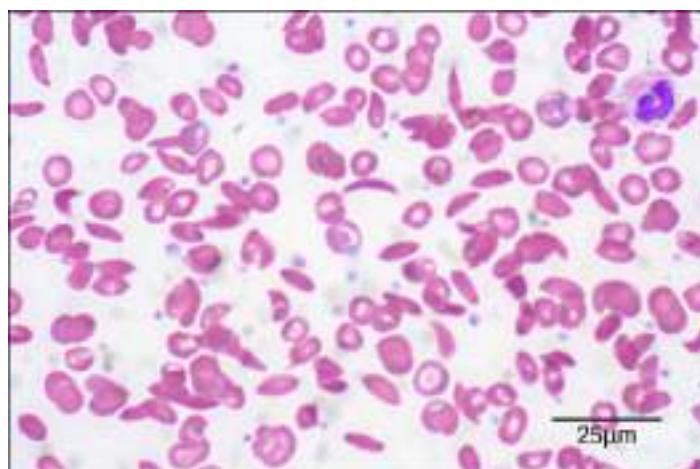

- a. The blood pH will drop and hemoglobin affinity for oxygen will increase.
- b. The blood pH will increase and hemoglobin affinity for oxygen will drop.
- c. The blood pH will drop and hemoglobin affinity for oxygen will decrease.
- d. The blood pH will increase and hemoglobin affinity for oxygen will also increase.

### Factors That Affect Oxygen Binding

The **oxygen-carrying capacity** of hemoglobin determines how much oxygen is carried in the blood. In addition to  $P_{O_2}$ , other environmental factors and diseases can affect oxygen carrying capacity and delivery.

Carbon dioxide levels, blood pH, and body temperature affect oxygen-carrying capacity (Figure 30.20). When carbon dioxide is in the blood, it reacts with water to form bicarbonate ( $HCO_3^-$ ) and hydrogen ions ( $H^+$ ). As the level of carbon dioxide in the blood increases, more  $H^+$  is produced and the pH decreases. This increase in carbon dioxide and subsequent decrease in pH reduce the affinity of hemoglobin for oxygen. The oxygen dissociates from the Hb molecule, shifting the oxygen dissociation curve to the right. Therefore, more oxygen is needed to reach the same hemoglobin saturation level as when the pH was higher. A similar shift in the curve also results from an increase in body temperature. Increased temperature, such as from increased activity of skeletal muscle, causes the affinity of hemoglobin for oxygen to be reduced.

Diseases like sickle cell anemia and thalassemia decrease the blood's ability to deliver oxygen to tissues and its oxygen-carrying capacity. In **sickle cell anemia**, the shape of the red blood cell is crescent-shaped, elongated, and stiffened, reducing its ability to deliver oxygen (Figure 30.21). In this form, red blood cells cannot pass through the capillaries. This is painful when it occurs. **Thalassemia** is a rare genetic disease caused by a defect in either the alpha or the beta subunit of Hb. Patients with thalassemia produce a high number of red blood cells, but these cells have lower-than-normal levels of hemoglobin. Therefore, the oxygen-carrying capacity is diminished.

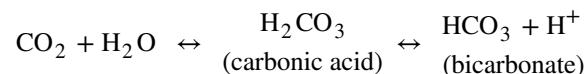

**Figure 30.21** Individuals with sickle cell anemia have crescent-shaped red blood cells. (credit: modification of work by Ed Uthman; scale-bar data from Matt Russell)

## Transport of Carbon Dioxide in the Blood

Carbon dioxide molecules are transported in the blood from body tissues to the lungs by one of three methods: dissolution directly into the blood, binding to hemoglobin, or carried as a bicarbonate ion. Several properties of carbon dioxide in the blood affect its transport. First, carbon dioxide is more soluble in blood than oxygen. About 5 to 7 percent of all carbon dioxide is dissolved in the plasma. Second, carbon dioxide can bind to plasma proteins or can enter red blood cells and bind to hemoglobin. This form transports about 10 percent of the carbon dioxide. When carbon dioxide binds to hemoglobin, a molecule called **carbaminohemoglobin** is formed. Binding of carbon dioxide to hemoglobin is reversible. Therefore, when it reaches the lungs, the carbon dioxide can freely dissociate from the hemoglobin and be expelled from the body.

Third, the majority of carbon dioxide molecules (85 percent) are carried as part of the **bicarbonate buffer system**. In this system, carbon dioxide diffuses into the red blood cells. **Carbonic anhydrase (CA)** within the red blood cells quickly converts the carbon dioxide into carbonic acid ( $H_2CO_3$ ). Carbonic acid is an unstable intermediate molecule that immediately dissociates into **bicarbonate ions ( $HCO_3^-$ )** and hydrogen ( $H^+$ ) ions. Since carbon dioxide is quickly converted into bicarbonate ions, this reaction allows for the continued uptake of carbon dioxide into the blood down its concentration gradient. It also results in the production of  $H^+$  ions. If too much  $H^+$  is produced, it can alter blood pH. However, hemoglobin binds to the free  $H^+$  ions and thus limits shifts in pH. The newly synthesized bicarbonate ion is transported out of the red blood cell into the liquid component of the blood in exchange for a chloride ion ( $Cl^-$ ); this is called the **chloride shift**. When the blood reaches the lungs, the bicarbonate ion is transported back into the red blood cell in exchange for the chloride ion. The  $H^+$  ion dissociates from the hemoglobin and binds to the bicarbonate ion. This produces the carbonic acid intermediate, which is converted back into carbon dioxide through the enzymatic action of CA. The carbon dioxide produced is expelled through the lungs during exhalation.

The benefit of the bicarbonate buffer system is that carbon dioxide is “soaked up” into the blood with little change to the pH of the system. This is important because it takes only a small change in the overall pH of the body for severe injury or death to result. The presence of this bicarbonate buffer system also allows for people to travel and live at high altitudes: When the partial pressure of oxygen and carbon dioxide change at high altitudes, the bicarbonate buffer system adjusts to regulate carbon dioxide while maintaining the correct pH in the body.

### Carbon Monoxide Poisoning

While carbon dioxide can readily associate and dissociate from hemoglobin, other molecules such as carbon monoxide (CO) cannot. Carbon monoxide has a greater affinity for hemoglobin than oxygen. Therefore, when carbon monoxide is present, it binds to hemoglobin preferentially over oxygen. As a result, oxygen cannot bind to hemoglobin, so very little oxygen is transported through the body (Figure 30.22). Carbon monoxide is a colorless, odorless gas and is therefore difficult to detect. It is produced by gas-powered vehicles and tools. Carbon monoxide can cause headaches, confusion, and nausea; long-term exposure can cause brain damage or death. Administering 100 percent (pure) oxygen is the usual treatment for carbon monoxide poisoning. Administration of pure oxygen speeds up the separation of carbon monoxide from hemoglobin.

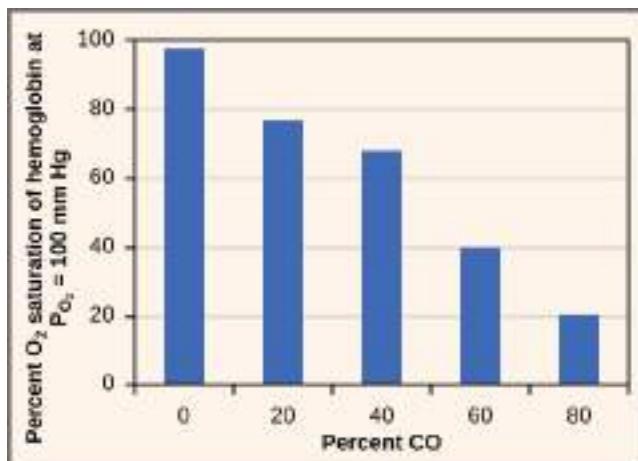

Figure 30.22 As percent CO increases, the oxygen saturation of hemoglobin decreases.

## science practices CONNECTION for AP<sup>®</sup> Courses

### Think About It

How does the administration of 100 percent oxygen save a patient from carbon monoxide poisoning? Why wouldn't giving carbon dioxide work?

## everyday CONNECTION for AP<sup>®</sup> Courses

Fuel burning items around the home can leak carbon monoxide gas. Because it is tasteless and odorless, people might not be aware of the leak, putting them at great risk for carbon monoxide poisoning. Carbon monoxide detectors, such as the one pictured here, have saved countless lives by alerting people to a dangerous build-up of carbon monoxide.

**Figure 30.23** (credit: Sideroxylon, Wikimedia Commons)

Why is it more important to have a detector for carbon monoxide than other household gases, such as ammonia or natural gas?

- a. Because carbon monoxide is tasteless and has a light odor, which is detected very late in exposure.
- b. Because carbon monoxide has a stronger odor, making it more unpleasant and dangerous.
- c. Because carbon monoxide is odorless and tasteless, unlike ammonia and household natural gas which have distinct smells.
- d. Because carbon monoxide should not be present in the environment at all.

## KEY TERMS

**alveolar  $P_{O_2}$**  partial pressure of oxygen in the alveoli (usually around 100 mmHg)

**alveolar duct** duct that extends from the terminal bronchiole to the alveolar sac

**alveolar sac** structure consisting of two or more alveoli that share a common opening

**alveolar ventilation** how much air is in the alveoli

**alveolus** (plural: alveoli) (also, air sac) terminal region of the lung where gas exchange occurs

**anatomical dead space** (also, anatomical shunt) region of the lung that lacks proper ventilation/perfusion due to an anatomical block

**bicarbonate ( $HCO_3^-$ ) ion** ion created when carbonic acid dissociates into  $H^+$  and  $(HCO_3^-)$

**bicarbonate buffer system** system in the blood that absorbs carbon dioxide and regulates pH levels

**bronchiole** airway that extends from the main tertiary bronchi to the alveolar sac

**bronchus** (plural: bronchi) smaller branch of cartilaginous tissue that stems off of the trachea; air is funneled through the bronchi to the region where gas exchange occurs in alveoli

**carbaminohemoglobin** molecule that forms when carbon dioxide binds to hemoglobin

**carbonic anhydrase (CA)** enzyme that catalyzes carbon dioxide and water into carbonic acid

**chloride shift** chloride shift exchange of chloride for bicarbonate into or out of the red blood cell

**compliance** measurement of the elasticity of the lung

**dead space** area in the lung that lacks proper ventilation or perfusion

**diaphragm** domed-shaped skeletal muscle located under lungs that separates the thoracic cavity from the abdominal cavity

**elastic recoil** property of the lung that drives the lung tissue inward

**elastic work** work conducted by the intercostal muscles, chest wall, and diaphragm

**expiratory reserve volume (ERV)** amount of additional air that can be exhaled after a normal exhalation

**FEV1/FVC ratio** ratio of how much air can be forced out of the lung in one second to the total amount that is forced out of the lung; a measurement of lung function that can be used to detect disease states

**flow-resistive** work of breathing performed by the alveoli and tissues in the lung

**forced expiratory volume (FEV)** (also, forced vital capacity) measure of how much air can be forced out of the lung from maximal inspiration over a specific amount of time

**functional residual capacity (FRC)** expiratory reserve volume plus residual volume

**functional vital capacity (FVC)** amount of air that can be forcibly exhaled after taking the deepest breath possible

**heme group** centralized iron-containing group that is surrounded by the alpha and beta subunits of hemoglobin

**hemoglobin** molecule in red blood cells that can bind oxygen, carbon dioxide, and carbon monoxide

**inspiratory capacity (IC)** tidal volume plus inspiratory reserve volume

**inspiratory reserve volume (IRV)** amount of additional air that can be inspired after a normal inhalation

**intercostal muscle** muscle connected to the rib cage that contracts upon inspiration

**intrapleural space** space between the layers of pleura

**larynx** voice box, a short passageway connecting the pharynx and the trachea

**lung capacity** measurement of two or more lung volumes (how much air can be inhaled from the end of an expiration to maximal capacity)

**lung volume** measurement of air for one lung function (normal inhalation or exhalation)

**mucin** complex glycoprotein found in mucus

**mucus** sticky protein-containing fluid secretion in the lung that traps particulate matter to be expelled from the body

**nasal cavity** opening of the respiratory system to the outside environment

**obstructive disease** disease (such as emphysema and asthma) that arises from obstruction of the airways; compliance increases in these diseases

**oxygen dissociation curve** curve depicting the affinity of oxygen for hemoglobin

**oxygen-carrying capacity** amount of oxygen that can be transported in the blood

**partial pressure** amount of pressure exerted by one gas within a mixture of gases

**particulate matter** small particle such as dust, dirt, viral particles, and bacteria that are in the air

**pharynx** throat; a tube that starts in the internal nares and runs partway down the neck, where it opens into the esophagus and the larynx

**physiological dead space** (also, physiological shunt) region of the lung that lacks proper ventilation/perfusion due to a physiological change in the lung (like inflammation or edema)

**pleura** tissue layer that surrounds the lungs and lines the interior of the thoracic cavity

**pleurisy** painful inflammation of the pleural tissue layers

**primary bronchus** (also, main bronchus) region of the airway within the lung that attaches to the trachea and bifurcates to each lung where it branches into secondary bronchi

**recruitment** process of opening airways that normally remain closed when the cardiac output increases

**residual volume (RV)** amount of air remaining in the lung after a maximal expiration

**resistance** measurement of lung obstruction

**respiratory bronchiole** terminal portion of the bronchiole tree that is attached to the terminal bronchioles and alveoli ducts, alveolar sacs, and alveoli

**respiratory distress syndrome** disease that arises from a deficient amount of surfactant

**respiratory quotient (RQ)** ratio of carbon dioxide production to each oxygen molecule consumed

**respiratory rate** number of breaths per minute

**restrictive disease** disease that results from a restriction and decreased compliance of the alveoli; respiratory distress syndrome and pulmonary fibrosis are examples

**sickle cell anemia** genetic disorder that affects the shape of red blood cells, and their ability to transport oxygen and move through capillaries

**spirometry** method to measure lung volumes and to diagnose lung diseases

**surfactant** detergent-like liquid in the airways that lowers the surface tension of the alveoli to allow for expansion

**terminal bronchiole** region of bronchiole that attaches to the respiratory bronchioles

**thalassemia** rare genetic disorder that results in mutation of the alpha or beta subunits of hemoglobin, creating smaller red blood cells with less hemoglobin

**tidal volume (TV)** amount of air that is inspired and expired during normal breathing

**total lung capacity (TLC)** sum of the residual volume, expiratory reserve volume, tidal volume, and inspiratory reserve volume

**trachea** cartilaginous tube that transports air from the larynx to the primary bronchi

**venous  $P_{CO_2}$**  partial pressure of carbon dioxide in the veins (40 mm Hg in the pulmonary veins)

**venous  $P_{O_2}$**  partial pressure of oxygen in the veins (100 mm Hg in the pulmonary veins)

**ventilation/perfusion (V/Q) mismatch** region of the lung that lacks proper alveolar ventilation (V) and/or arterial perfusion (Q)

**vital capacity (VC)** sum of the expiratory reserve volume, tidal volume, and inspiratory reserve volume

## CHAPTER SUMMARY

### 30.1 Systems of Gas Exchange

Animal respiratory systems are designed to facilitate gas exchange. In mammals, air is warmed and humidified in the nasal cavity. Air then travels down the pharynx, through the trachea, and into the lungs. In the lungs, air passes through the branching bronchi, reaching the respiratory bronchioles, which house the first site of gas exchange. The respiratory bronchioles open into the alveolar ducts, alveolar sacs, and alveoli. Because there are so many alveoli and alveolar sacs in the lung, the surface area for gas exchange is very large. Several protective mechanisms are in place to prevent damage or infection. These include the hair and mucus in the nasal cavity that trap dust, dirt, and other particulate matter before they can enter the system. In the lungs, particles are trapped in a mucus layer and transported via cilia up to the esophageal opening at the top of the trachea to be swallowed.

### 30.2 Gas Exchange across Respiratory Surfaces

The lungs can hold a large volume of air, but they are not usually filled to maximal capacity. Lung volume measurements include tidal volume, expiratory reserve volume, inspiratory reserve volume, and residual volume. The sum of these equals the total lung capacity. Gas movement into or out of the lungs is dependent on the pressure of the gas. Air is a mixture of gases; therefore, the partial pressure of each gas can be calculated to determine how the gas will flow in the lung. The difference between the partial pressure of the gas in the air drives oxygen into the tissues and carbon dioxide out of the body.

### 30.3 Breathing

The structure of the lungs and thoracic cavity control the mechanics of breathing. Upon inspiration, the diaphragm contracts and lowers. The intercostal muscles contract and expand the chest wall outward. The intrapleural pressure drops, the lungs expand, and air is drawn into the airways. When exhaling, the intercostal muscles and diaphragm relax, returning the intrapleural pressure back to the resting state. The lungs recoil and airways close. The air passively exits the lung. There is high surface tension at the air-airway interface in the lung. Surfactant, a mixture of phospholipids and lipoproteins, acts like a detergent in the airways to reduce surface tension and allow for opening of the alveoli.

Breathing and gas exchange are both altered by changes in the compliance and resistance of the lung. If the compliance of the lung decreases, as occurs in restrictive diseases like fibrosis, the airways stiffen and collapse upon exhalation. Air becomes trapped in the lungs, making breathing more difficult. If resistance increases, as happens with asthma or emphysema, the airways become obstructed, trapping air in the lungs and causing breathing to become difficult. Alterations in the ventilation of the airways or perfusion of the arteries can affect gas exchange. These changes in ventilation and perfusion, called V/Q mismatch, can arise from anatomical or physiological changes.

### 30.4 Transport of Gases in Human Bodily Fluids

Hemoglobin is a protein found in red blood cells that is comprised of two alpha and two beta subunits that surround an iron-containing heme group. Oxygen readily binds this heme group. The ability of oxygen to bind increases as more oxygen molecules are bound to heme. Disease states and altered conditions in the body can affect the binding ability of oxygen, and increase or decrease its ability to dissociate from hemoglobin.

Carbon dioxide can be transported through the blood via three methods. It is dissolved directly in the blood, bound to plasma proteins or hemoglobin, or converted into bicarbonate. The majority of carbon dioxide is transported as part of the bicarbonate system. Carbon dioxide diffuses into red blood cells. Inside, carbonic anhydrase converts carbon dioxide into carbonic acid ( $\text{H}_2\text{CO}_3$ ), which is subsequently hydrolyzed into bicarbonate ( $\text{HCO}_3^-$ ) and  $\text{H}^+$ . The  $\text{H}^+$  ion binds to

hemoglobin in red blood cells, and bicarbonate is transported out of the red blood cells in exchange for a chloride ion. This is called the chloride shift. Bicarbonate leaves the red blood cells and enters the blood plasma. In the lungs, bicarbonate is transported back into the red blood cells in exchange for chloride. The  $\text{H}^+$  dissociates from hemoglobin and combines with bicarbonate to form carbonic acid with the help of carbonic anhydrase, which further catalyzes the reaction to convert carbonic acid back into carbon dioxide and water. The carbon dioxide is then expelled from the lungs.

## REVIEW QUESTIONS

1. What is the primary function of the respiratory system?

- a. provides body tissues with oxygen
- b. provides body tissues with oxygen and carbon dioxide
- c. establishes how many breaths are taken per minute
- d. provides the body with carbon dioxide

2. What is the order of airflow during inhalation?

- a. nasal cavity, larynx, trachea, bronchi, bronchioles, alveoli
- b. nasal cavity, larynx, trachea, bronchioles, bronchi, alveoli
- c. nasal cavity, trachea, larynx, bronchi, bronchioles, alveoli
- d. nasal cavity, trachea, larynx, bronchi, bronchioles, alveoli

3. What advantages does warming air within the nasal passages provide?

- a. reduces rates of lung infection
- b. prevents foreign objects from entering the lungs
- c. prevents cell damage caused by cold air
- d. reduces fluid accumulation from cold, wet air

4. Emphysema is a disease characterized by a great reduction in the number of functioning alveoli in the lungs. What effect would emphysema likely have on the respiratory system?

- a. Less gas exchange would occur with the blood.
- b. Less air could travel through the trachea.
- c. Air could no longer pass through the nasal cavity.
- d. Air could no longer vibrate the vocal cords of the larynx.

5. The inspiratory reserve volume measures the \_\_\_\_.

- a. amount of air remaining in the lung after a maximal exhalation
- b. amount of air the lung holds
- c. amount of air that can be further exhaled after a normal breath
- d. amount of air that can be further inhaled after a normal breath

6. The total lung capacity is calculated using which formula?

- a. residual volume + tidal volume + inspiratory reserve volume
- b. residual volume + expiratory reserve volume + inspiratory reserve volume
- c. expiratory reserve volume + tidal volume + inspiratory reserve volume
- d. residual volume + expiratory reserve volume + tidal volume + inspiratory reserve volume

7. Why is the partial pressure of oxygen lower in the lung than in the external air?

- a. Oxygen is constantly being removed by air in the lungs through the blood.
- b. Carbon dioxide does not mix with oxygen in the lung.
- c. The lungs exert pressure on the air to reduce the oxygen pressure.
- d. Changes in water vapor pressure cause less oxygen to enter the air in the lungs.

8. How can a decrease in the percent of oxygen in the air affect the movement of oxygen in the body?

- a. It would not affect the rate of diffusion into the blood because there would be no difference between the partial pressures of the air and blood.
- b. It would decrease the rate of diffusion into the blood because it increases the difference between the partial pressures of the air and blood.
- c. It would increase the rate of diffusion into the blood because it reduces the difference between the partial pressures of the air and blood.
- d. It would decrease the rate of diffusion into the blood because it reduces the difference between the partial pressures of the air and blood.
- 9.** What role do the intercostal muscles play in inspiration and expiration?
- They move down, causing inspiration, and move up, causing expiration.
  - They move up, causing inspiration, and move down, causing expiration.
  - They relax, causing inspiration, and contract, causing expiration.
  - They contract, causing inspiration, and relax, causing expiration.
- 10.** How would paralysis of the diaphragm alter inspiration?
- It would prevent contraction of the intercostal muscles.
  - It would prevent inhalation because the intrapleural pressure would not change.
  - It would decrease the intrapleural pressure and allow more air to enter the lungs.
  - It would slow expiration because the lung would not relax.
- 11.** Restrictive airway diseases \_\_\_\_\_.
- increase the compliance of the lung
  - decrease the compliance of the lung
  - increase the lung volume
  - decrease the work of breathing
- 12.** A patient is suffering from an allergic reaction that causes his airways to swell up. How would this most likely affect resistance of the respiratory system, and why?
- a. Resistance decreases because it will be harder for air to flow through the airways.
- b. Resistance decreases because the airways are more compliant.
- c. Resistance increases because it will be harder for air to flow through the airways.
- d. Resistance increases because the airways are more compliant.
- 13.** What is a physiological dead space and what could be its cause?
- A physiological dead space is a region of lung tissue that is leaking air. It could be caused by a puncture wound.
  - A physiological dead space is a region of lung tissue that is not receiving electrical stimulation from the nervous system. It could be caused by a reduction in neurotransmitters.
  - A physiological dead space is a region of lung tissue that is not involved in gas exchange because the tissue is not functioning properly. It could be caused by the alveoli capillaries are not receiving blood flow.
  - A physiological dead space is a region of lung tissue that is not involved in gas exchange because the tissue has a defect in its structure. It could be caused by a genetic condition.
- 14.** How will the respiratory rate and volume of air per breath change if alveolar ventilation is too high or too low?
- If ventilation is low, the respiratory rate will decrease while the volume of air per breath is decreased. If ventilation is high, the respiratory rate will increase while the volume of air per breath decreases.
  - If ventilation is low, the respiratory rate will decrease while the volume of air per breath is increased. If ventilation is high, the respiratory rate will increase while the volume of air per breath decreases.
  - If ventilation is low, the respiratory rate will increase while the volume of air per breath is decreased. If ventilation is high, the respiratory rate will increase while the volume of air per breath increases.
  - If ventilation is low, the respiratory rate will increase while the volume of air per breath is decreased. If ventilation is high, the respiratory rate will increase while the volume of air per breath decreases.
- 15.** What does elastic recoil in the lungs refer to and does it aid inspiration or expiration?

- a. the ability of the diaphragm to contract and relax to change the volume of the lung, inspiration
  - b. the reserve air in the lungs that is present even after maximum exhalation, expiration
  - c. the ability of the bronchioles to expand and retract as air enters and exits, inspiration
  - d. the ability of lung tissue to exert pressure back towards the lung's interior, expiration
- 16.** Low pH in the blood will \_\_\_\_ hemoglobin's affinity for \_\_\_\_.
- a. increase, carbon dioxide
  - b. increase, oxygen
  - c. decrease, carbon dioxide
  - d. decrease, oxygen
- 17.** Which of the following will not facilitate the transfer of oxygen to tissues?
- a. decreased body temperature
  - b. decreased pH of the blood
  - c. increased carbon dioxide
  - d. increased exercise
- 18.** How is the majority of carbon dioxide in the blood transported?
- a. binding to hemoglobin
  - b. dissolution in the blood
  - c. as bicarbonate
  - d. binding to plasma proteins
- 19.** How is the chloride shift related to the transport of carbon dioxide in the blood?
- a. It allows carbon dioxide, in the form of bicarbonate ions, to enter the blood plasma.
  - b. It creates carbaminohemoglobin within the red blood cells.
  - c. It allows the conversion of carbon dioxide into carbonic acid within red blood cells.
  - d. It prevents the formation of bicarbonate ions in the blood.

## CRITICAL THINKING QUESTIONS

- 20.** How does the structure of alveoli maximize gas exchange?
- a. Their sac-like structure increases their surface area.
  - b. Their direct connection to the bronchi maximizes their access to air.
  - c. They actively transport the gases between the air and blood.
  - d. They are spheres that fully fill with blood, which will come in contact with air.
- 21.** What structures of the respiratory system warm and remove impurities from inhaled air?
- a. The epiglottis deflects impurities out of the trachea and into the esophagus, while the nasal cavity warms the air.
  - b. Hair and mucus in the nose and trachea catch impurities, while the nasal cavity warms the air.
  - c. Saliva in the mouth and hair in the trachea catch impurities, while the pharynx warms the air.
  - d. The closed-off compartments of the larynx trap impurities in the air and warm the air.
- 22.** If you were travelling in a miniaturized ship through the respiratory system, from the pharynx to an alveolus, which structures would you pass along the way, and in what order?
- 23.** What does FEV<sub>1</sub>/FVC measure and why will the ratio increase with lung fibrosis?
- a. the forced expiratory volume in one second in relation to the total forced vital capacity; lung fibrosis causes the lungs to decrease in size
  - b. the functional expiratory volume in one second in relation to the total functional vital capacity; lung fibrosis causes the lungs to decrease in size
  - c. the functional expiratory volume in one second in relation to the total functional vital capacity; lung fibrosis causes the lungs to become less pliable
  - d. the forced expiratory volume in one second in relation to the total forced vital capacity; lung fibrosis causes the lungs to become less pliable
- 24.** Compare the partial pressure of oxygen between venous blood in an alveolus and air and between arterial blood and body tissues?
- a. trachea, larynx, bronchi, and bronchioles
  - b. larynx, trachea, bronchi, and bronchioles
  - c. bronchioles, bronchi, trachea, and larynx
  - d. bronchioles, trachea, bronchi, and larynx

- a. higher in the blood than in the air and higher in the blood than in the body tissues
- b. lower in the blood than in the air and higher in the blood than in the body tissues
- c. higher in the blood than in the air and lower in the blood than in the body tissues
- d. lower in the blood than in the air and lower in the blood than in the body tissues
- 25.** What conditions of the lungs would cause a an increase in FEV1/FVC? What about a decrease FEV1/ FVC?
- This ratio increases as the lungs become stiff and less pliable, increasing further when there is increased resistance in the lung.
  - This ratio decreases as the lungs become stiff and less pliable, increasing when there is increased resistance in the lung.
  - This ratio increases as the lungs become stiff and less pliable, decreasing when there is increased resistance in the lung.
  - This ratio decreases as the lungs become stiff and less pliable, decreasing further when there is increased resistance in the lung.
- 26.** Amphibians, such as frogs, breathe by collecting air in a pouch below their throat. Muscles then contract the pouch and force air into their lungs. How does this differ from inhalation in humans and other mammals?
- Inhalation in humans and other mammals involves the openings called spiracles, which connect to the tubular network to allow the oxygen to pass into the body.
  - Inhalation in humans and other mammals involve direct diffusion across the outer membrane to meet oxygen requirements. Gases can diffuse quickly through direct diffusion.
  - Inhalation in humans and other mammals involve contracting the thoracic cavity by creating negative pressure in the lungs, which causes air to diffuse into the lungs.
  - Inhalation in humans and other mammals involves expanding the thoracic cavity by creating negative pressure in the lungs, which causes air to diffuse into the lungs.
- 27.** If a patient has increased resistance in his or her lungs, how can this be detected by a doctor? What does this mean?
- a. This can be detected using a nebulizer. By detecting the rate at which air can be taken into the lung, a diagnosis of a restrictive disease can be made.
- b. This can be detected using spirometry. By detecting the rate at which air can be taken into the lung, a diagnosis of a restrictive disease can be made.
- c. This can be detected using a nebulizer. By detecting the rate at which air can be expelled from the lung, a diagnosis of a restrictive disease can be made.
- d. This can be detected using spirometry. By detecting the rate at which air can be expelled from the lung, a diagnosis of a restrictive disease can be made.
- 28.** When someone is standing, gravity stretches the bottom of the lung down toward the floor to a greater extent than the top of the lung. What implication could this have on ventilation in the lungs?
- Concentration gradient leads to increased ventilation further down in the lung.
  - Pleural pressure gradient leads to increased ventilation further down in the lung.
  - Pleural pressure gradient leads to decreased ventilation further down in the lung.
  - Concentration gradient leads to decreased ventilation further down in the lung.
- 29.** How does the administration of 100 percent oxygen save a patient from carbon monoxide poisoning? Why wouldn't giving carbon dioxide work?
- At that concentration, oxygen will be transported in the body at a high rate by dissolving in blood. Oxygen has more affinity for hemoglobin than carbon dioxide.
  - At that concentration, oxygen will displace the carbon monoxide from the hemoglobin. Oxygen has more affinity for hemoglobin than carbon dioxide.
  - At that concentration, oxygen will displace the carbon monoxide from the hemoglobin. Carbon dioxide has more affinity for hemoglobin than oxygen.
  - At that concentration, oxygen will be transported in the body at a high rate by dissolving in blood. Carbon dioxide has more affinity for hemoglobin than oxygen.
- 30.** What would happen if no carbonic anhydrase was present in red blood cells?

- a. Carbon dioxide would be hydrolyzed into carbonic acid or bicarbonate. The maximum amount of carbon dioxide would be transported in the blood away from the tissues.
- b. Carbon dioxide would not be hydrolyzed into carbonic acid or bicarbonate. The maximum amount of carbon dioxide would be transported in the blood away from the tissues.
- c. Oxygen would not be hydrolyzed into carbonic acid or bicarbonate. Only 15 percent of carbon dioxide would be transported in the blood away from the tissues.
- d. Carbon dioxide would not be hydrolyzed into carbonic acid or bicarbonate. Only 15 percent of carbon dioxide would be transported in the blood away from the tissues.

## TEST PREP FOR AP® COURSES

32.

The cell of the unicellular algae *Ventricaria ventricosa* is one of the largest known, reaching one to five centimeters in diameter. Like all single-celled organisms, *V. ventricosa* exchanges gases across the cell membrane. What adaptations would *V. ventricosa* likely have evolved related to its large size and ability to exchange materials with the outside environment?

- a. adaptations that would decrease cell metabolism to meet the needs of the large cell
- b. adaptations that would make the cell thicker, to reduce the loss of nutrients
- c. adaptations that make diffusion or nutrient passage across their cell membrane more efficient due to the large size of the cell
- d. adaptations that allow the cell to take in larger food objects using the components of its cell membrane

31. What is sickle cell anemia and how does it affect the perfusion of oxygen in the blood?

- a. It is a genetic disease in which red blood cells are sickle-shaped, reducing oxygen perfusion into the blood.
- b. It is a genetic disease in which red blood cells are sickle-shaped, increasing oxygen perfusion into the blood.
- c. It is a deficiency disease in which red blood cells are sickle-shaped, reducing oxygen perfusion into the blood.
- d. It is a deficiency disease in which red blood cells are sickle-shaped, increasing oxygen perfusion into the blood.

33. In the past, the Earth has experienced environmental changes, which have changed the amount of available oxygen and carbon dioxide in the water and air. For example, there is evidence of less oxygen available in the air during the time of the dinosaurs, a result of high volcanic activity creating a large amount of carbon dioxide. How might red blood cells in the dinosaurs have evolved, in terms of size and shape, to adapt to the lower-oxygen atmosphere?

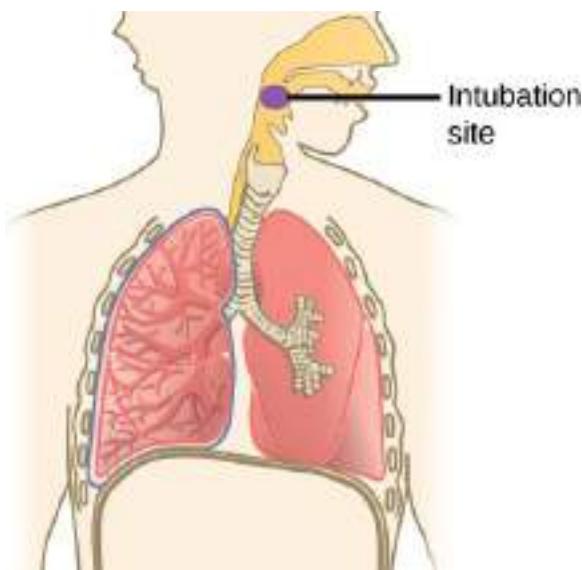

- a. evolve smaller size and flatter shape.
- b. evolve larger size and a pointy shape.
- c. evolve smaller size and a thicker shape.
- d. evolve larger size and a shorter shape.

34. **Figure 30.10** shows a human alveolus, which is part of the respiratory system. What do arrows A and B represent in the diagram?

- a. A: inhaled air; B: blood travelling from the heart
- b. A: exhaled air; B: blood travelling from the heart
- c. A: inhaled air; B: blood travelling to the heart
- d. A: exhaled air; B: blood traveling from the heart

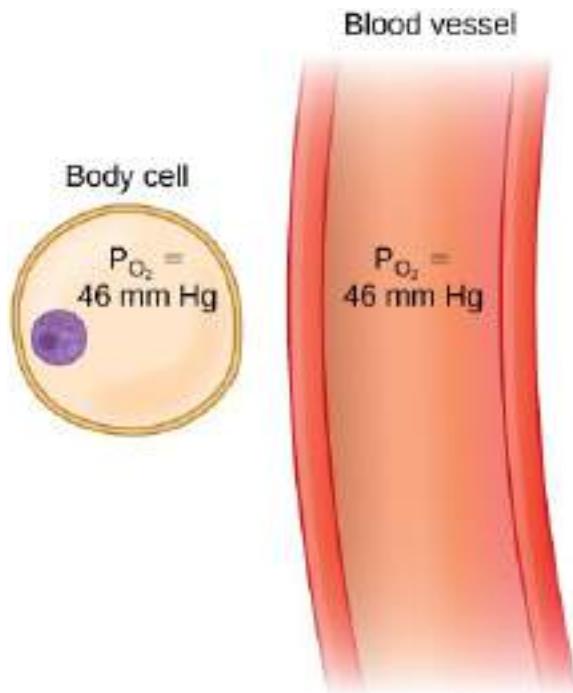

35. Intubation is a procedure used by ambulance crews that allows a person to breathe if part of the respiratory system is blocked by a foreign object (or otherwise injured). During intubation, a long, plastic tube is placed in the respiratory system so that air can bypass the obstructed area and reach the lungs. Typically, air is supplied artificially using a squeezable bag that connects to the top of the tube. The illustration shows the human respiratory system. The nasal cavity is a wide cavity above and behind the nostrils, and the pharynx is the passageway behind the mouth. The nasal cavity and pharynx join and enter the trachea through the larynx. The larynx is somewhat wider than the trachea and flat. The trachea has concentric, ring-like grooves, giving it a bumpy appearance. The trachea

bifurcates into two primary bronchi, which are also grooved. The primary bronchi enter the lungs, and branch into secondary bronchi. The secondary bronchi in turn branch into many tertiary bronchi. The tertiary bronchi branch into bronchioles, which branch into terminal bronchioles. The diaphragm pushes up against the lungs. There is an intubation site indicated at the beginning of the pharynx. A patient has been surgically intubated in the location shown in the diagram. Based on this information, explain where the injury likely occurred in the patient's respiratory system. Justify your answer.

- in the oral cavity, because it is above the injury
- in the oral cavity, because it is below the injury
- in the larynx, because it is above the injury
- in the larynx, because it is below the injury

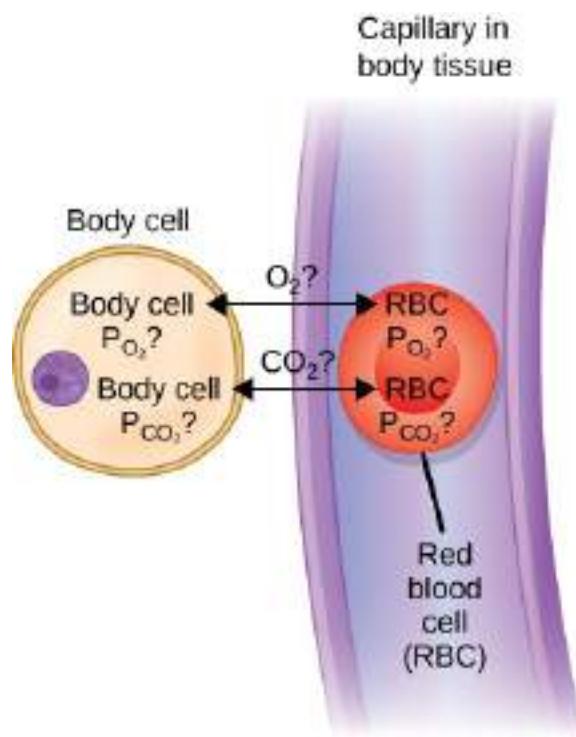

36.

Our body systems work to maintain homeostasis by adjusting when body cells need more oxygen or are experiencing a buildup of carbon dioxide. How would the body likely respond if some of its cells were experiencing the situation pictured?

- Generating neural signals that stimulate the heart to beat at a faster rate.
- Releasing hormones that stimulate body cells to undergo more active transport.
- Releasing red blood cells that can accept oxygen using diffusion as opposed to facilitated passive transport.
- Adjust blood pH to decrease the partial pressure of CO<sub>2</sub> in the body cells.

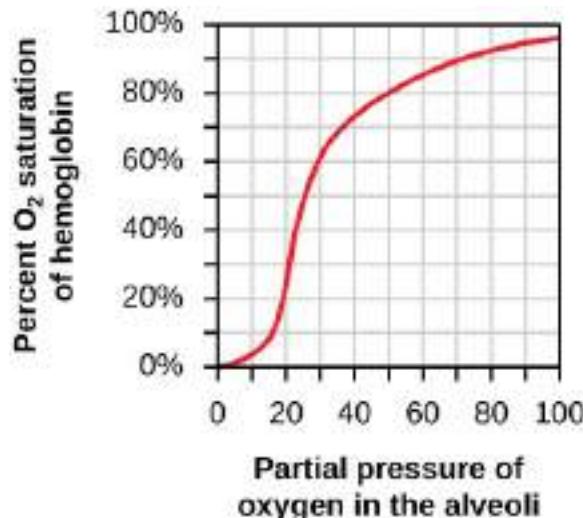

37.

The diagram shows a red blood cell in an alveolus and then in a body tissue. In which direction should the arrows point for the diffusion of oxygen and  $CO_2$ ? How should each partial pressure (body cell and RBC) be labeled as “high” or “low” to accomplish this diffusion?

- $O_2 \rightarrow CO_2 \leftarrow$ ; Body cell  $PO_2$ = low; RBC  $PO_2$ = high; Body cell  $PCO_2$ = high, RBC  $PCO_2$ = low
- $O_2 \leftarrow CO_2 \rightarrow$ ; Body cell  $PO_2$ = high; RBC  $PO_2$ = low; Body cell  $PCO_2$ = low, RBC  $PCO_2$ = high
- $O_2 \leftarrow CO_2 \rightarrow$ ; Body cell  $PO_2$ = low; RBC  $PO_2$ = high; Body cell  $PCO_2$ = high, RBC  $PCO_2$ = low
- $O_2 \rightarrow CO_2 \leftarrow$ ; Body cell  $PO_2$ = high; RBC  $PO_2$ = low; Body cell  $PCO_2$ = low, RBC  $PCO_2$ = high

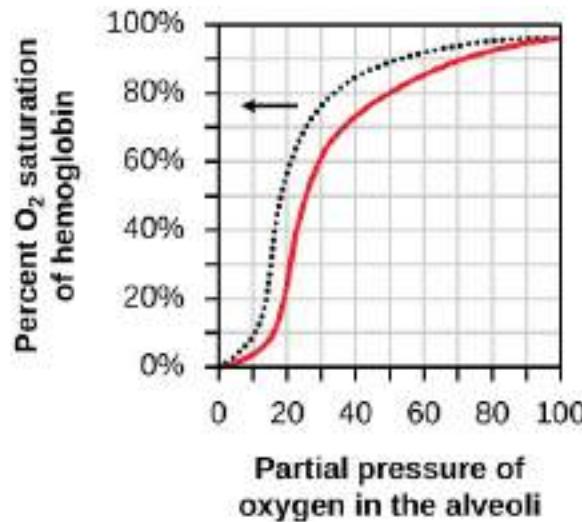

38.

The graph plots percent oxygen saturation of hemoglobin as a function of oxygen partial pressure in the alveoli. Oxygen saturation increases in an S-shaped curve, from 0 to 100 percent as the partial pressure of oxygen increases from 0 to 100. What happens as the curve levels off around a partial pressure of 60 mmHg?

- As the percent saturation of hemoglobin increases to its maximum, hemoglobin’s affinity for oxygen increases as the availability of oxygen increases.
- As the percent saturation of hemoglobin decreases (without all of the oxygen dissociating), hemoglobin’s affinity for oxygen decreases as the availability of oxygen decreases.
- As the percent saturation of hemoglobin increases to very high levels, hemoglobin’s affinity for oxygen decreases due to its decreasing ability to bind oxygen.
- As the percent saturation of hemoglobin decreases, hemoglobin’s affinity for oxygen increases as the availability of oxygen decreases.

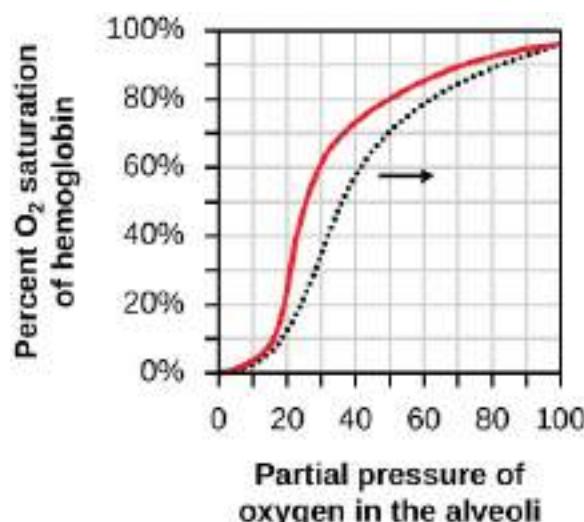

39.

The graph shows an oxygen dissociation curve for hemoglobin. Based on the graph, what would likely cause the curve to shift to the left, as shown by the dotted plot line?

- a decrease in carbon dioxide, increase in pH, or a decrease in temperature
- an increase in carbon dioxide, increase in pH, or a decrease in temperature
- a decrease in carbon dioxide, decrease in pH, or a decrease in temperature
- a decrease in carbon dioxide, increase in pH, or an increase in temperature

40.

The graph shows an oxygen dissociation curve for hemoglobin. Based on the graph, what would likely cause the curve to shift to the right, as shown by the dotted plot line?

- decreasing carbon dioxide, increasing pH, or decreasing temperature
- decreasing carbon dioxide, decreasing pH, or increasing temperature
- increasing carbon dioxide, increasing pH or increasing temperature.
- increasing carbon dioxide, decreasing pH, or increasing temperature.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**41.** Oxygen deprivation produces symptoms such as fatigue, headaches, and confusion that are collectively referred to as hypoxia. A vacation in the Rocky Mountains of the US, where the partial pressure of oxygen is just 15% lower than you are accustomed to on the coast, can induce these symptoms. The body has a very narrow range of environment oxygen tolerance. It essentially has no capacity for storage of oxygen that is continuously consumed to maintain energy homeostasis.

The response to oxygen deprivation is to increase breathing rate and increase the volume of each breath. The input for a negative feedback loop that maintains homeostasis by detecting oxygen concentrations is a sensor (the carotid body) located on the interior of carotid artery. The output is at the diaphragm. The signal is processed in the respiratory centers (RCs) of the medulla in the brainstem.

A. **Describe** how the nervous system integrates information about oxygen concentration in the blood to maintain homeostasis. In your description include the concepts of negative feedback and a set point.

An alternative model (Evens et al., *Biochemical Journal*, 473, 2016) of the response to oxygen deprivation is suggested by the observation that high-altitude Andean populations have a gene for a protein kinase (AMPK encoded by *PRKAA1*) that has a fixed single nucleotide variation. This AMP-activated kinase is coupled with mitochondrial oxidative phosphorylation to detect reduced oxygen and signal the RCs of the medulla directly—a distributed network for detection and response. The authors of this work note that a homologous gene in yeast

allows colony-wide signaling to switch individuals in the colony from glycolysis to oxidative phosphorylation in response to changes in glucose resources.

B. **Describe** the connection of a changing environment to changing genomes in both species in terms of the adaptive advantage provided and the likelihood that an AMPK signaling process has been conserved across domains.

Studies of a genetic adaptation in Tibetan population have shown that other mutations have been selected. One mutation *EPAS1* was shown to be correlated with increased lactic acid concentrations in the blood. Another mutation, *PPARA*, was found to be correlated with fatty acid production, which is typically seen during hibernation (Ge et al., *Molecular Genetics and Metabolism*, 106, 2012; Lorenzo et al., *Nature Genetics*, 46, 2014)

C. **Analyze** these observations in terms of the regulation of metabolism due to changes in genetic makeup and construct an explanation for the divergence of the homeostatic mechanisms as an adaptation to the environment.

The Tibetan population is not isolated. However, these investigations show the near dominance of the mutated form of these two genes has arisen in just 8000 years. Neanderthal, Denisovans and ancestors of modern humans were contemporaries.

D. **Describe** conditions that lead to speciation in terms of the accumulation of many small genetic changes where very sharp differences in oxygen availability were geographically imposed.

# 31 | THE CIRCULATORY SYSTEM

**Figure 31.1** Just as highway systems transport people and goods through a complex network, the circulatory system transports nutrients, gases, and wastes throughout the animal body. (credit: modification of work by Andrey Belenko)

## Chapter Outline

- 31.1: Overview of the Circulatory System**
- 31.2: Components of the Blood**
- 31.3: Mammalian Heart and Blood Vessels**
- 31.4: Blood Flow and Blood Pressure Regulation**

## Introduction

Most animals are complex multicellular organisms that require a mechanism for transporting nutrients throughout their bodies and removing waste products. The circulatory system has evolved over time from simple diffusion through cells in the early evolution of animals to a complex network of blood vessels that reach all parts of the human body. This extensive network supplies the cells, tissues, and organs with oxygen and nutrients, and removes carbon dioxide and waste, which are byproducts of respiration.

At the core of the human circulatory system is the heart. The size of a clenched fist, the human heart is protected beneath the rib cage. Made of specialized and unique cardiac muscle, it pumps blood throughout the body and to the heart itself. Heart contractions are driven by intrinsic electrical impulses that the brain and endocrine hormones help to regulate.

Understanding the heart's basic anatomy and function is important to understanding the body's circulatory and respiratory systems. Because one in four deaths in the United States is due to heart disease, billions of dollars are spent each year researching ways to prevent and treat it. For example, researchers have been trying to find a way to get damaged cardiac muscle to repair itself. A team of researchers at the Weizmann Institute of Science recently discovered that activating a protein called ERBB2 causes heart cells in adult mice to regenerate. The research team is continuing their research to determine how this knowledge might be applied to human medicine. You can read more about this exciting research on the [Science Daily website \(<http://openstaxcollege.org/l/32ERBB2>\)](http://openstaxcollege.org/l/32ERBB2).

## 31.1 | Overview of the Circulatory System

In this section, you will explore the following questions:

- What is the difference between an open circulatory system and a closed circulatory system?
- What are the components of interstitial fluid and hemolymph?
- What are the differences and similarities among the organization and evolution of different vertebrate circulatory systems?

### Connection for AP® Courses

Much of the information in this chapter is not in scope for AP®. However, the chapter is filled with examples that are applicable to concepts we have previously explored. The circulatory system links to all other organ systems. For example, nutrients pass from the digestive system into the blood, and the excretory system rids the blood of wastes. In addition, because heart disease is a leading cause of death in humans, the information is relevant.

Circulatory systems in animals show a distinct pattern of evolution—from none in sponges and jellyfish to open circulatory systems characteristic of insects to closed circulatory systems with hearts, valves, and vessels in vertebrates. Circulatory systems provide body cells with oxygen and nutrients, remove wastes, transports hormones, protect against invaders, and aids in temperature regulation. Although some animals such as the sponge have had no adaptive need to develop a complex circulatory system (they exchange nutrients and wastes directly with the environment), as demands for oxygen increased with terrestrial living, natural selection favored a closed circulatory system in which blood is transported in vessels. To increase efficiency, within closed systems the heart evolved from two chambers in fish (one atrium and one ventricle) to the four-chambered heart (two atria and two ventricles) seen in crocodiles, birds, and mammals.

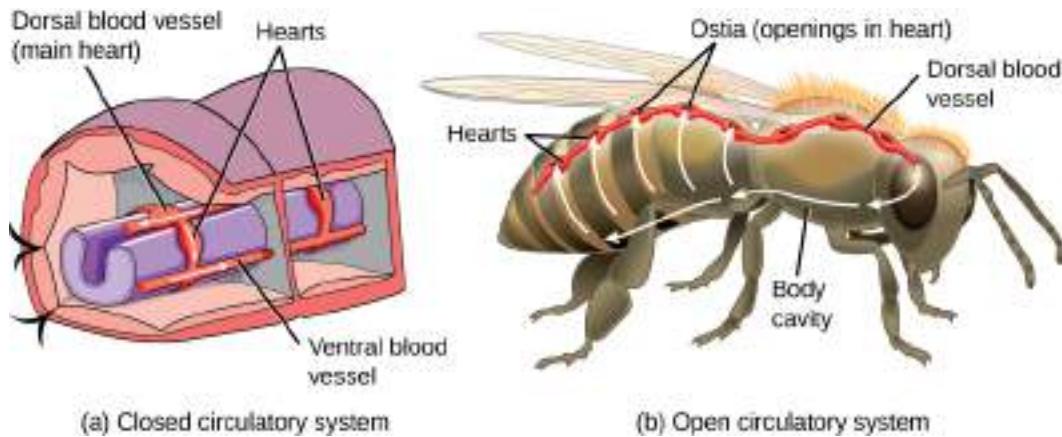

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 1 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Big Idea 1</b>                 | The process of evolution drives the diversity and unity of life.                                                                                                                                    |
| <b>Enduring Understanding 1.A</b> | Change in the genetic makeup of a population over time is evolution.                                                                                                                                |
| <b>Essential Knowledge</b>        | <b>1.A.1</b> An adaptation, such as the number of heart chambers, is a genetic variation that is favored by natural selection and provides an advantage to an organism in a particular environment. |
| <b>Science Practice</b>           | <b>2.2</b> The student can apply mathematical routines to quantities that describe natural phenomena.                                                                                               |
| <b>Science Practice</b>           | <b>5.3</b> The student can evaluate the evidence provided by data sets in relation to a particular scientific question.                                                                             |
| <b>Learning Objective</b>         | <b>1.2</b> The student is able to evaluate evidence provided by data to qualitatively and quantitatively investigate the role of natural selection in evolution.                                    |
| <b>Enduring Understanding 1.B</b> | Organisms are linked by lines of descent from common ancestry.                                                                                                                                      |
| <b>Essential Knowledge</b>        | <b>1.B.2</b> Phylogenetic trees and cladogram can represent traits, such as the number of heart chambers in animals, which are derived or lost due to evolution.                                    |
| <b>Science Practice</b>           | <b>3.1</b> The student can pose scientific questions.                                                                                                                                               |

|                            |                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Learning Objective</b>  | <b>1.17</b> The student is able to pose scientific questions about a group of organisms whose relatedness is described by a phylogenetic tree or cladogram in order to (1) identify shared characteristics, (2) make inferences about the evolutionary history of the group, and (3) identify character data that could extend or improve the phylogenetic tree. |
| <b>Essential Knowledge</b> | <b>1.B.2</b> Phylogenetic trees and cladogram can represent traits, such as the number of heart chambers in animals, which are derived or lost due to evolution.                                                                                                                                                                                                 |
| <b>Science Practice</b>    | <b>1.1</b> The student can create representations and models of natural or man-made phenomena and systems in the domain.                                                                                                                                                                                                                                         |
| <b>Learning Objective</b>  | <b>1.19</b> The student is able to create a phylogenetic tree or simple cladogram that correctly represents evolutionary history and speciation from a provided data set.                                                                                                                                                                                        |

## Circulatory System Architecture

The circulatory system is effectively a network of cylindrical vessels: the arteries, veins, and capillaries that emanate from a pump, the heart. In all vertebrate organisms, as well as some invertebrates, this is a closed-loop system, in which the blood is not free in a cavity. In a **closed circulatory system**, blood is contained inside blood vessels and circulates **unidirectionally** from the heart around the systemic circulatory route, then returns to the heart again, as illustrated in **Figure 31.2a**. As opposed to a closed system, arthropods—including insects, crustaceans, and most mollusks—have an open circulatory system, as illustrated in **Figure 31.2b**. In an **open circulatory system**, the blood is not enclosed in the blood vessels but is pumped into a cavity called a **hemocoel** and is called **hemolymph** because the blood mixes with the **interstitial fluid**. As the heart beats and the animal moves, the hemolymph circulates around the organs within the body cavity and then reenters the hearts through openings called **ostia**. This movement allows for gas and nutrient exchange. An open circulatory system does not use as much energy as a closed system to operate or to maintain; however, there is a trade-off with the amount of blood that can be moved to metabolically active organs and tissues that require high levels of oxygen. In fact, one reason that insects with wing spans of up to two feet wide (70 cm) are not around today is probably because they were outcompeted by the arrival of birds 150 million years ago. Birds, having a closed circulatory system, are thought to have moved more agilely, allowing them to get food faster and possibly to prey on the insects.

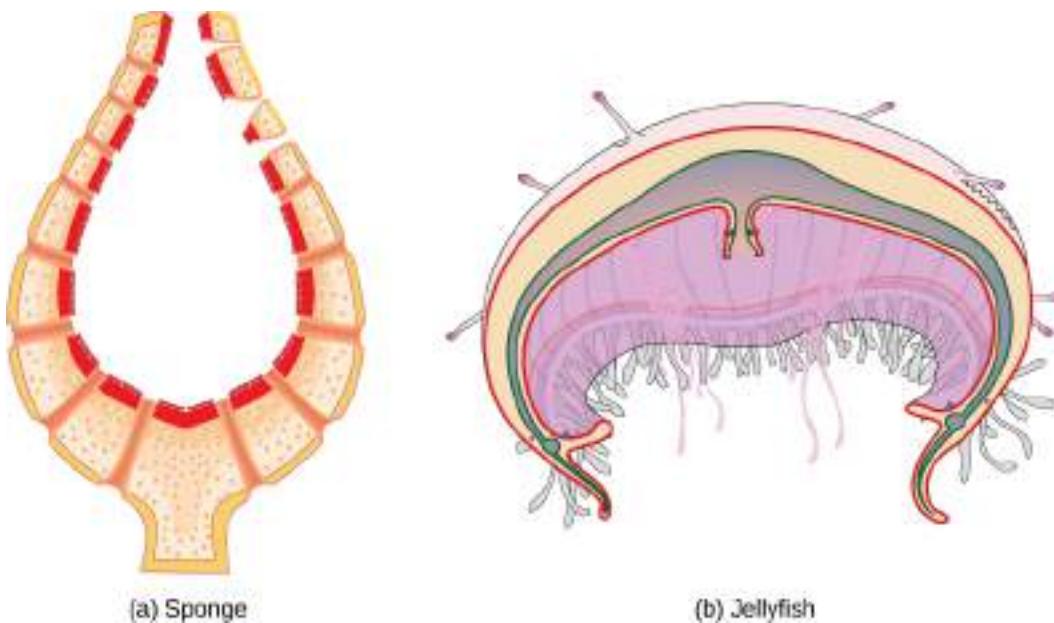

**Figure 31.2** In (a) closed circulatory systems, the heart pumps blood through vessels that are separate from the interstitial fluid of the body. Most vertebrates and some invertebrates, like this annelid earthworm, have a closed circulatory system. In (b) open circulatory systems, a fluid called hemolymph is pumped through a blood vessel that empties into the body cavity. Hemolymph returns to the blood vessel through openings called ostia. Arthropods like this bee and most mollusks have open circulatory systems.

## Circulatory System Variation in Animals

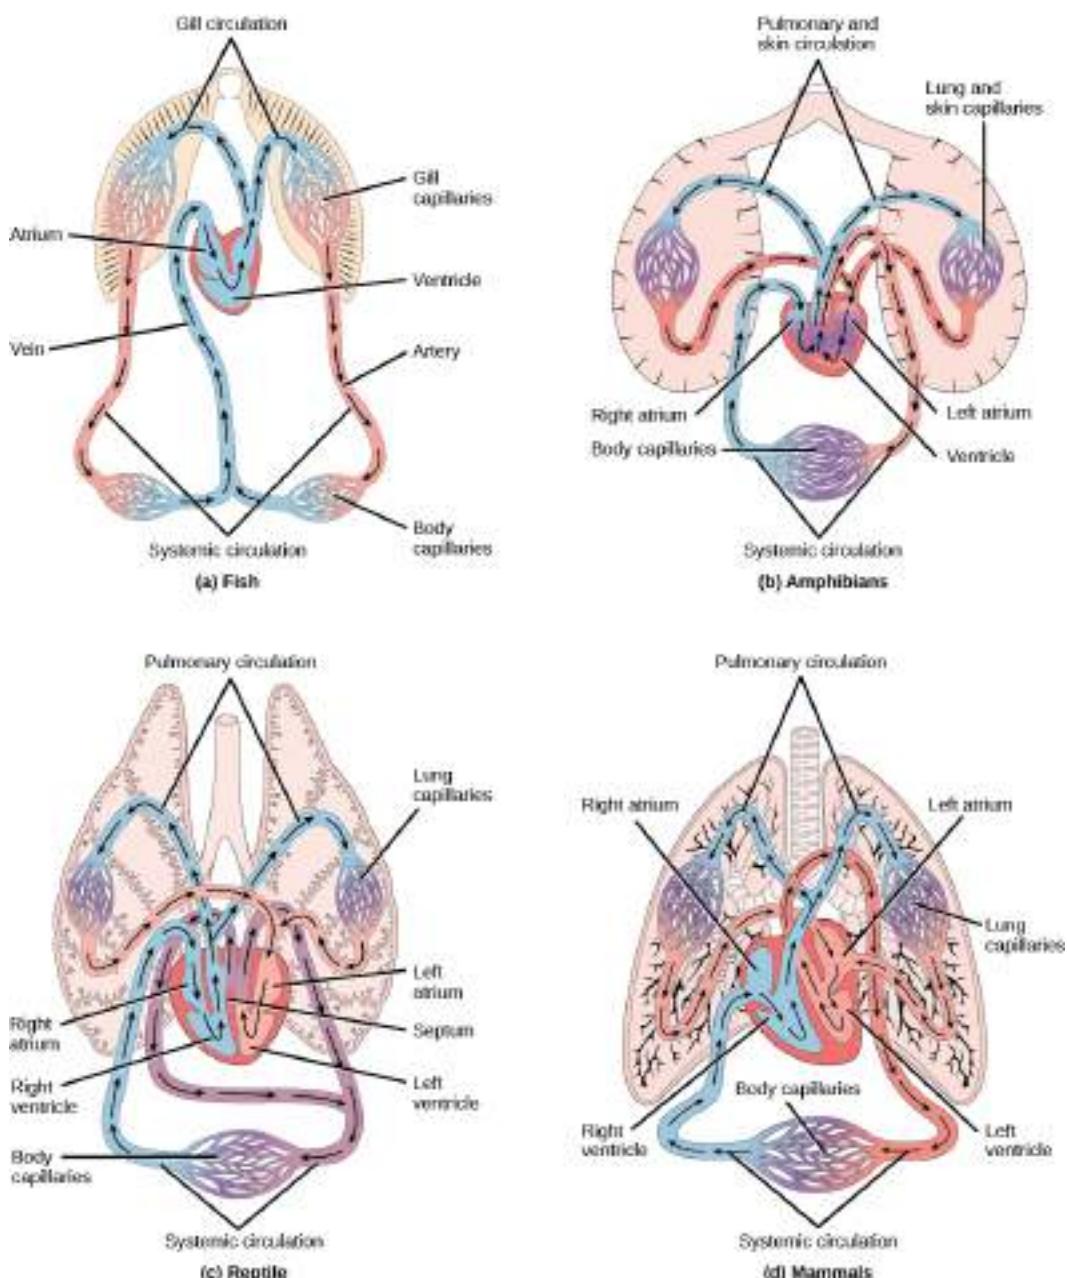

The circulatory system varies from simple systems in invertebrates to more complex systems in vertebrates. The simplest animals, such as the sponges (Porifera) and rotifers (Rotifera), do not need a circulatory system because diffusion allows adequate exchange of water, nutrients, and waste, as well as dissolved gases, as shown in **Figure 31.3a**. Organisms that are more complex but still only have two layers of cells in their body plan, such as jellies (Cnidaria) and comb jellies (Ctenophora) also use diffusion through their epidermis and internally through the gastrovascular compartment. Both their internal and external tissues are bathed in an aqueous environment and exchange fluids by diffusion on both sides, as

illustrated in **Figure 31.3b**. Exchange of fluids is assisted by the pulsing of the jellyfish body.

**Figure 31.3** Simple animals consisting of a single cell layer such as the (a) sponge or only a few cell layers such as the (b) jellyfish do not have a circulatory system. Instead, gases, nutrients, and wastes are exchanged by diffusion.

For more complex organisms, diffusion is not efficient for cycling gases, nutrients, and waste effectively through the body; therefore, more complex circulatory systems evolved. Most arthropods and many mollusks have open circulatory systems. In an open system, an elongated beating heart pushes the hemolymph through the body and muscle contractions help to move fluids. The larger more complex crustaceans, including lobsters, have developed arterial-like vessels to push blood through their bodies, and the most active mollusks, such as squids, have evolved a closed circulatory system and are able to move rapidly to catch prey. Closed circulatory systems are a characteristic of vertebrates; however, there are significant differences in the structure of the heart and the circulation of blood between the different vertebrate groups due to adaptation during evolution and associated differences in anatomy. **Figure 31.4** illustrates the basic circulatory systems of some vertebrates: fish, amphibians, reptiles, and mammals.

**Figure 31.4** (a) Fish have the simplest circulatory systems of the vertebrates: blood flows unidirectionally from the two-chambered heart through the gills and then the rest of the body. (b) Amphibians have two circulatory routes: one for oxygenation of the blood through the lungs and skin, and the other to take oxygen to the rest of the body. The blood is pumped from a three-chambered heart with two atria and a single ventricle. (c) Reptiles also have two circulatory routes; however, blood is only oxygenated through the lungs. The heart is three chambered, but the ventricles are partially separated so some mixing of oxygenated and deoxygenated blood occurs except in crocodilians and birds. (d) Mammals and birds have the most efficient heart with four chambers that completely separate the oxygenated and deoxygenated blood; it pumps only oxygenated blood through the body and deoxygenated blood to the lungs.

As illustrated in **Figure 31.4a** Fish have a single circuit for blood flow and a two-chambered heart that has only a single atrium and a single ventricle. The atrium collects blood that has returned from the body and the ventricle pumps the blood to the gills where gas exchange occurs and the blood is re-oxygenated; this is called **gill circulation**. The blood then continues through the rest of the body before arriving back at the atrium; this is called **systemic circulation**. This unidirectional flow of blood produces a gradient of oxygenated to deoxygenated blood around the fish's systemic circuit. The result is a limit in the amount of oxygen that can reach some of the organs and tissues of the body, reducing the overall metabolic capacity of fish.

In amphibians, reptiles, birds, and mammals, blood flow is directed in two circuits: one through the lungs and back to the

heart, which is called **pulmonary circulation**, and the other throughout the rest of the body and its organs including the brain (systemic circulation). In amphibians, gas exchange also occurs through the skin during pulmonary circulation and is referred to as **pulmocutaneous circulation**.

As shown in **Figure 31.4b**, amphibians have a three-chambered heart that has two atria and one ventricle rather than the two-chambered heart of fish. The two **atria** (superior heart chambers) receive blood from the two different circuits (the lungs and the systems), and then there is some mixing of the blood in the heart's **ventricle** (inferior heart chamber), which reduces the efficiency of oxygenation. The advantage to this arrangement is that high pressure in the vessels pushes blood to the lungs and body. The mixing is mitigated by a ridge within the ventricle that diverts oxygen-rich blood through the systemic circulatory system and deoxygenated blood to the pulmocutaneous circuit. For this reason, amphibians are often described as having **double circulation**.

Most reptiles also have a three-chambered heart similar to the amphibian heart that directs blood to the pulmonary and systemic circuits, as shown in **Figure 31.4c**. The ventricle is divided more effectively by a partial septum, which results in less mixing of oxygenated and deoxygenated blood. Some reptiles (alligators and crocodiles) are the most primitive animals to exhibit a four-chambered heart. Crocodilians have a unique circulatory mechanism where the heart shunts blood from the lungs toward the stomach and other organs during long periods of submergence, for instance, while the animal waits for prey or stays underwater waiting for prey to rot. One adaptation includes two main arteries that leave the same part of the heart: one takes blood to the lungs and the other provides an alternate route to the stomach and other parts of the body. Two other adaptations include a hole in the heart between the two ventricles, called the foramen of Panizza, which allows blood to move from one side of the heart to the other, and specialized connective tissue that slows the blood flow to the lungs. Together these adaptations have made crocodiles and alligators one of the most evolutionarily successful animal groups on earth.

In mammals and birds, the heart is also divided into four chambers: two atria and two ventricles, as illustrated in **Figure 31.4d**. The oxygenated blood is separated from the deoxygenated blood, which improves the efficiency of double circulation and is probably required for the warm-blooded lifestyle of mammals and birds. The four-chambered heart of birds and mammals evolved independently from a three-chambered heart. The independent evolution of the same or a similar biological trait is referred to as convergent evolution.

## science practices CONNECTION for AP<sup>®</sup> Courses

### Think About It

What advantages are supplied by closed circulatory systems with chambered hearts in terrestrial vertebrates?

## 31.2 | Components of the Blood

In this section, you will explore the following questions:

- What are the basic components of blood?
- What are the differences between red blood cells and white blood cells?
- What is the difference between blood plasma and blood serum?

### Connection for AP<sup>®</sup> Courses

Most of us have suffered a cut or a scraped knee and have seen our own blood. Blood consists of different types of cells bathed in a water-based liquid called plasma. Red blood cells are specialized to carry hemoglobin (Hgb), a quaternary protein that transports oxygen and some carbon dioxide around the body, to and from the heart and lungs. Hemoglobin also has an affinity for carbon monoxide, a toxic and deadly gas. Variants of hemoglobin help animals adapt to different environments. For example, Hgb-S causes sickle-cell anemia; although this variant of hemoglobin is not as efficient at transporting O<sub>2</sub>, it does provide some protection against malaria, thus providing an advantage to heterozygous individuals. Another variant is Hgb-F or fetal hemoglobin, which transports O<sub>2</sub> efficiently in low oxygen conditions. Red blood cells develop and mature in the bone marrow and when released into circulation lack nuclei and mitochondria. Blood types such

as A, B, AB, and O are related to proteins on the surface of red blood cells. For example, persons with type A blood have A glycoproteins on the surface of their red blood cells. We will take a deeper dive into blood typing, antigens, and antibodies when we explore the immune system in a later chapter, and we also will learn in that the five types of white blood cells play important roles in immunity. Platelets and plasma proteins function in normal blood clotting; alterations in the feedback mechanism(s) that result in normal clotting can have deleterious effects, including hemophilia and stroke.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 and Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

Hemoglobin is responsible for distributing oxygen, and to a lesser extent, carbon dioxide, throughout the circulatory systems of humans, vertebrates, and many invertebrates. The blood is more than the proteins, though. Blood is actually a term used to describe the liquid that moves through the vessels and includes **plasma** (the liquid portion, which contains water, proteins, salts, lipids, and glucose) and the cells (red and white cells) and cell fragments called **platelets**. Blood plasma is actually the dominant component of blood and contains the water, proteins, electrolytes, lipids, and glucose. The cells are responsible for carrying the gases (red cells) and immune response (white). The platelets are responsible for blood clotting. Interstitial fluid that surrounds cells is separate from the blood, but in hemolymph, they are combined. In humans, cellular components make up approximately 45 percent of the blood and the liquid plasma 55 percent. Blood is 20 percent

of a person's extracellular fluid and eight percent of weight.

## The Role of Blood in the Body

Blood, like the human blood illustrated in **Figure 31.5** is important for regulation of the body's systems and homeostasis. Blood helps maintain homeostasis by stabilizing pH, temperature, osmotic pressure, and by eliminating excess heat. Blood supports growth by distributing nutrients and hormones, and by removing waste. Blood plays a protective role by transporting clotting factors and platelets to prevent blood loss and transporting the disease-fighting agents or **white blood cells** to sites of infection.

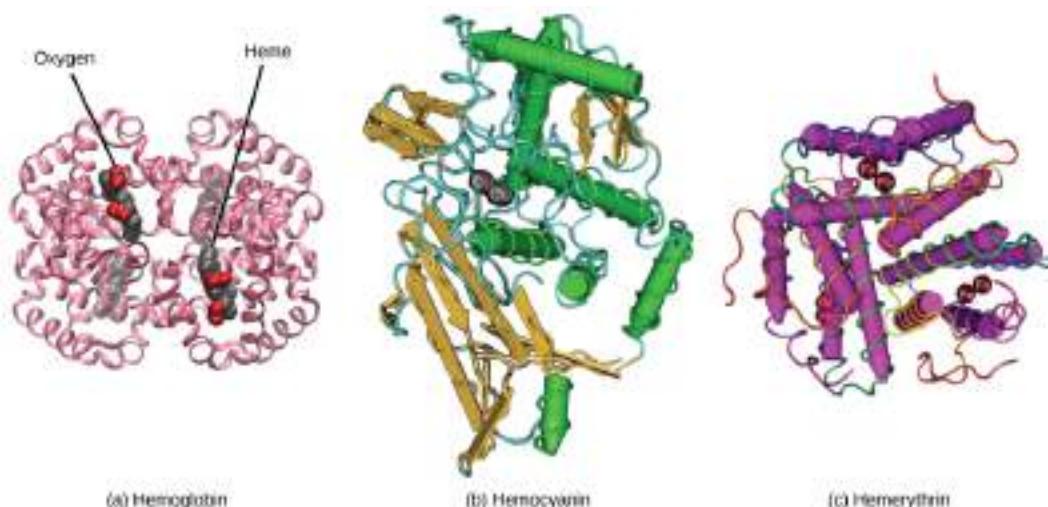

**Figure 31.5** The cells and cellular components of human blood are shown. Red blood cells deliver oxygen to the cells and remove carbon dioxide. White blood cells—including neutrophils, monocytes, lymphocytes, eosinophils, and basophils—are involved in the immune response. Platelets form clots that prevent blood loss after injury.

## Red Blood Cells

**Red blood cells**, or erythrocytes (*erythro-* = “red”; *-cyte* = “cell”), are specialized cells that circulate through the body delivering oxygen to cells; they are formed from stem cells in the bone marrow. In mammals, red blood cells are small biconcave cells that at maturity do not contain a nucleus or mitochondria and are only 7–8  $\mu\text{m}$  in size. In birds and non-avian reptiles, a nucleus is still maintained in red blood cells.

The red coloring of blood comes from the iron-containing protein hemoglobin, illustrated in **Figure 31.6a**. The principal job of this protein is to carry oxygen, but it also transports carbon dioxide as well. Hemoglobin is packed into red blood cells at a rate of about 250 million molecules of hemoglobin per cell. Each hemoglobin molecule binds four oxygen molecules so that each red blood cell carries one billion molecules of oxygen. There are approximately 25 trillion red blood cells in the five liters of blood in the human body, which could carry up to 25 sextillion ( $25 \times 10^{21}$ ) molecules of oxygen in the body at any time. In mammals, the lack of organelles in erythrocytes leaves more room for the hemoglobin molecules, and the lack of mitochondria also prevents use of the oxygen for metabolic respiration. Only mammals have anucleated red blood cells, and some mammals (camels, for instance) even have nucleated red blood cells. The advantage of nucleated red blood cells is that these cells can undergo mitosis. Anucleated red blood cells metabolize anaerobically (without oxygen), making use of a primitive metabolic pathway to produce ATP and increase the efficiency of oxygen transport.

Not all organisms use hemoglobin as the method of oxygen transport. Invertebrates that utilize hemolymph rather than blood use different pigments to bind to the oxygen. These pigments use copper or iron to bind the oxygen. Invertebrates have a variety of other respiratory pigments. Hemocyanin, a blue-green, copper-containing protein, illustrated in **Figure 31.6b** is found in mollusks, crustaceans, and some of the arthropods. Chlorocruorin, a green-colored, iron-containing pigment is found in four families of polychaete tubeworms. Hemerythrin, a red, iron-containing protein is found in some polychaete worms and annelids and is illustrated in **Figure 31.6c**. Despite the name, hemerythrin does not contain a heme group and its oxygen-carrying capacity is poor compared to hemoglobin.

**Figure 31.6** In most vertebrates, (a) hemoglobin delivers oxygen to the body and removes some carbon dioxide. Hemoglobin is composed of four protein subunits, two alpha chains and two beta chains, and a heme group that has iron associated with it. The iron reversibly associates with oxygen, and in so doing is oxidized from  $\text{Fe}^{2+}$  to  $\text{Fe}^{3+}$ . In most mollusks and some arthropods, (b) hemocyanin delivers oxygen. Unlike hemoglobin, hemolymph is not carried in blood cells, but floats free in the hemolymph. Copper instead of iron binds the oxygen, giving the hemolymph a blue-green color. In annelids, such as the earthworm, and some other invertebrates, (c) hemerythrin carries oxygen. Like hemoglobin, hemerythrin is carried in blood cells and has iron associated with it, but despite its name, hemerythrin does not contain heme.

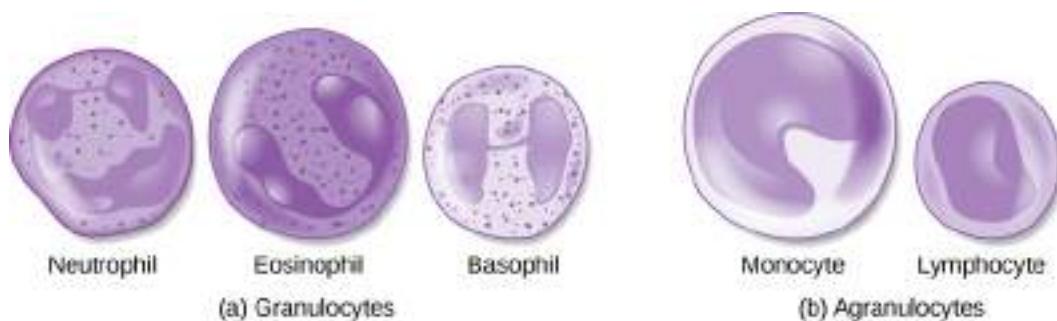

The small size and large surface area of red blood cells allows for rapid diffusion of oxygen and carbon dioxide across the plasma membrane. In the lungs, carbon dioxide is released and oxygen is taken in by the blood. In the tissues, oxygen is released from the blood and carbon dioxide is bound for transport back to the lungs. Studies have found that hemoglobin also binds nitrous oxide (NO). NO is a vasodilator that relaxes the blood vessels and capillaries and may help with gas exchange and the passage of red blood cells through narrow vessels. Nitroglycerin, a heart medication for angina and heart attacks, is converted to NO to help relax the blood vessels and increase oxygen flow through the body.

A characteristic of red blood cells is their glycolipid and glycoprotein coating; these are lipids and proteins that have carbohydrate molecules attached. In humans, the surface glycoproteins and glycolipids on red blood cells vary between individuals, producing the different blood types, such as A, B, and O. Red blood cells have an average life span of 120 days, at which time they are broken down and recycled in the liver and spleen by phagocytic macrophages, a type of white blood cell.

## White Blood Cells

White blood cells, also called leukocytes (leuko = white), make up approximately one percent by volume of the cells in blood. The role of white blood cells is very different than that of red blood cells: they are primarily involved in the immune response to identify and target pathogens, such as invading bacteria, viruses, and other foreign organisms. White blood cells are formed continually; some only live for hours or days, but some live for years.

The morphology of white blood cells differs significantly from red blood cells. They have nuclei and do not contain hemoglobin. The different types of white blood cells are identified by their microscopic appearance after histologic staining, and each has a different specialized function. The two main groups, both illustrated in **Figure 31.7** are the granulocytes, which include the neutrophils, eosinophils, and basophils, and the agranulocytes, which include the monocytes and lymphocytes.

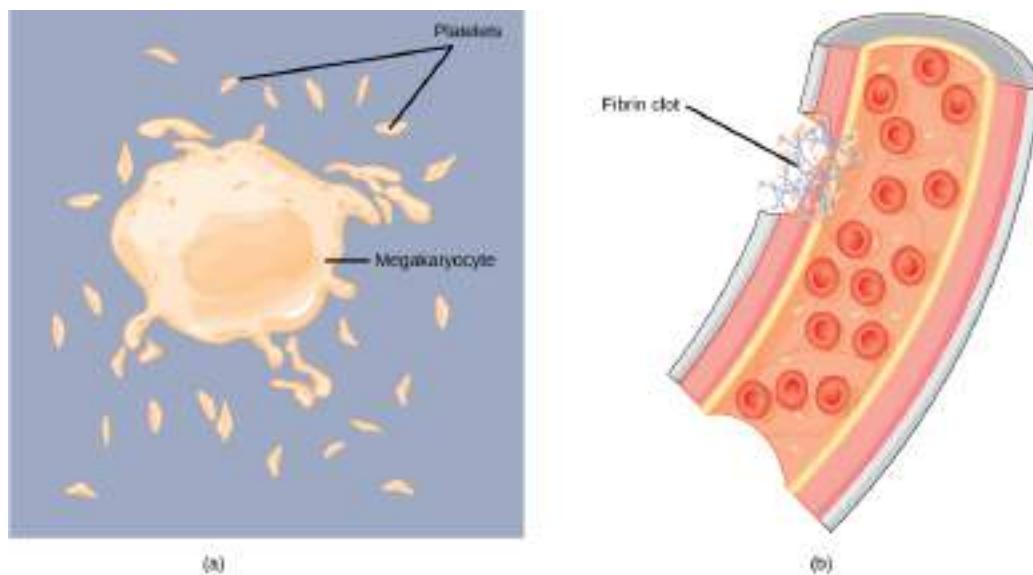

**Figure 31.7** (a) Granulocytes—including neutrophils, eosinophils and basophils—are characterized by a lobed nucleus and granular inclusions in the cytoplasm. Granulocytes are typically first-responders during injury or infection. (b) Agranulocytes include lymphocytes and monocytes. Lymphocytes, including B and T cells, are responsible for adaptive immune response. Monocytes differentiate into macrophages and dendritic cells, which in turn respond to infection or injury.

Granulocytes contain granules in their cytoplasm; the agranulocytes are so named because of the lack of granules in their cytoplasm. Some leukocytes become macrophages that either stay at the same site or move through the blood stream and gather at sites of infection or inflammation where they are attracted by chemical signals from foreign particles and damaged cells. Lymphocytes are the primary cells of the immune system and include B cells, T cells, and natural killer cells. B cells destroy bacteria and inactivate their toxins. They also produce antibodies. T cells attack viruses, fungi, some bacteria, transplanted cells, and cancer cells. T cells attack viruses by releasing toxins that kill the viruses. Natural killer cells attack a variety of infectious microbes and certain tumor cells.

One reason that HIV poses significant management challenges is because the virus directly targets T cells by gaining entry through a receptor. Once inside the cell, HIV then multiplies using the T cell's own genetic machinery. After the HIV virus replicates, it is transmitted directly from the infected T cell to macrophages. The presence of HIV can remain unrecognized for an extensive period of time before full disease symptoms develop.

## Platelets and Coagulation Factors

Blood must clot to heal wounds and prevent excess blood loss. Small cell fragments called platelets (thrombocytes) are attracted to the wound site where they adhere by extending many projections and releasing their contents. These contents activate other platelets and also interact with other coagulation factors, which convert fibrinogen, a water-soluble protein present in blood serum into fibrin (a non-water soluble protein), causing the blood to clot. Many of the clotting factors require vitamin K to work, and vitamin K deficiency can lead to problems with blood clotting. Many platelets converge and stick together at the wound site forming a platelet plug (also called a fibrin clot), as illustrated in **Figure 31.8b**. The plug or clot lasts for a number of days and stops the loss of blood. Platelets are formed from the disintegration of larger cells called megakaryocytes, like that shown in **Figure 31.8a**. For each megakaryocyte, 2000–3000 platelets are formed with 150,000 to 400,000 platelets present in each cubic millimeter of blood. Each platelet is disc shaped and 2–4  $\mu\text{m}$  in diameter. They contain many small vesicles but do not contain a nucleus.

**Figure 31.8** (a) Platelets are formed from large cells called megakaryocytes. The megakaryocyte breaks up into thousands of fragments that become platelets. (b) Platelets are required for clotting of the blood. The platelets collect at a wound site in conjunction with other clotting factors, such as fibrinogen, to form a fibrin clot that prevents blood loss and allows the wound to heal.

## Plasma and Serum

The liquid component of blood is called plasma, and it is separated by spinning or centrifuging the blood at high rotations (3000 rpm or higher). The blood cells and platelets are separated by centrifugal forces to the bottom of a specimen tube. The upper liquid layer, the plasma, consists of 90 percent water along with various substances required for maintaining the body's pH, osmotic load, and for protecting the body. The plasma also contains the coagulation factors and antibodies.

The plasma component of blood without the coagulation factors is called the **serum**. Serum is similar to interstitial fluid in which the correct composition of key ions acting as electrolytes is essential for normal functioning of muscles and nerves. Other components in the serum include proteins that assist with maintaining pH and osmotic balance while giving viscosity to the blood. The serum also contains antibodies, specialized proteins that are important for defense against viruses and bacteria. Lipids, including cholesterol, are also transported in the serum, along with various other substances including nutrients, hormones, metabolic waste, plus external substances, such as, drugs, viruses, and bacteria.

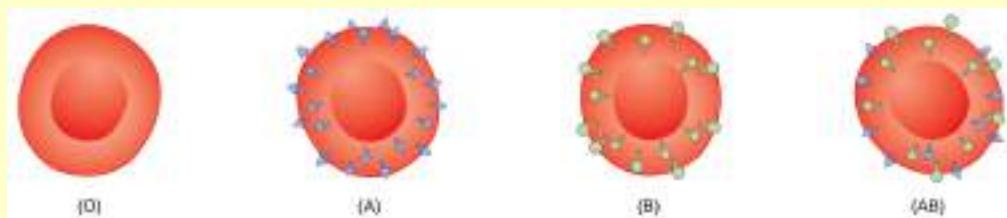

Human serum albumin is the most abundant protein in human blood plasma and is synthesized in the liver. Albumin, which constitutes about half of the blood serum protein, transports hormones and fatty acids, buffers pH, and maintains osmotic pressures. Immunoglobulin is a protein antibody produced in the mucosal lining and plays an important role in antibody mediated immunity.

# eVolution CONNECTION

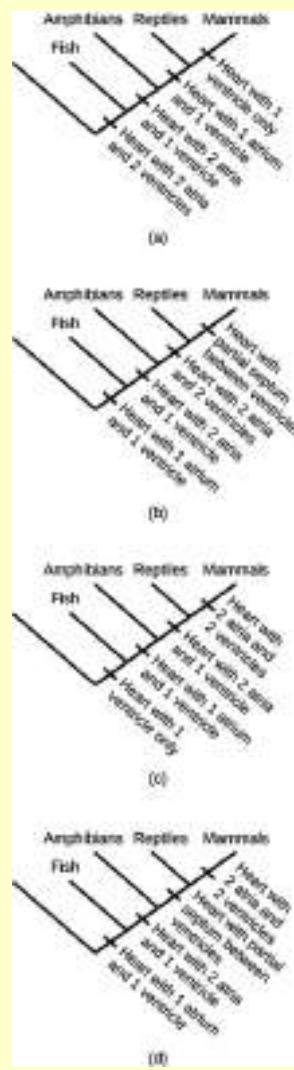

## Blood Types Related to Proteins on the Surface of the Red Blood Cells

Red blood cells are coated in antigens made of glycolipids and glycoproteins. The composition of these molecules is determined by genetics, which have evolved over time. In humans, the different surface antigens are grouped into 24 different blood groups with more than 100 different antigens on each red blood cell. The two most well known blood groups are the ABO, shown in **Figure 31.9**, and Rh systems. The surface antigens in the ABO blood group are glycolipids, called antigen A and antigen B. People with blood type A have antigen A, those with blood type B have antigen B, those with blood type AB have both antigens, and people with blood type O have neither antigen. Antibodies called agglutinogens are found in the blood plasma and react with the A or B antigens, if the two are mixed. When type A and type B blood are combined, agglutination (clumping) of the blood occurs because of antibodies in the plasma that bind with the opposing antigen; this causes clots that coagulate in the kidney causing kidney failure. Type O blood has neither A or B antigens, and therefore, type O blood can be given to all blood types. Type O negative blood is the universal donor. Type AB positive blood is the universal acceptor because it has both A and B antigen. The ABO blood groups were discovered in 1900 and 1901 by Karl Landsteiner at the University of Vienna.

The Rh blood group was first discovered in Rhesus monkeys. Most people have the Rh antigen (Rh+) and do not have anti-Rh antibodies in their blood. The few people who do not have the Rh antigen and are Rh– can develop anti-Rh antibodies if exposed to Rh+ blood. This can happen after a blood transfusion or after an Rh– woman has an Rh+ baby. The first exposure does not usually cause a reaction; however, at the second exposure, enough antibodies have built up in the blood to produce a reaction that causes agglutination and breakdown of red blood cells. An injection can prevent this reaction.

**Figure 31.9** Human red blood cells may have either type A or B glycoproteins on their surface, both glycoproteins combined (AB), or neither (O). The glycoproteins serve as antigens and can elicit an immune response in a person who receives a transfusion containing unfamiliar antigens. Type O blood, which has no A or B antigens, does not elicit an immune response when injected into a person of any blood type. Thus, O is considered the universal donor. Persons with type AB blood can accept blood from any blood type, and type AB is considered the universal acceptor.

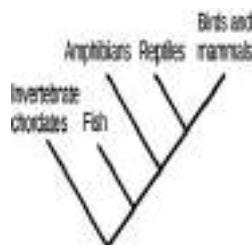

Which of the following phylogenies, created based on features of the circulatory system of vertebrates, is most accurate?

- a. A
- b. B
- c. C
- d. D

Play a blood typing game on the **Nobel Prize website** ([http://openstaxcollege.org/l/blood\\_typing](http://openstaxcollege.org/l/blood_typing)) to solidify your understanding of blood types.

This simplified phylogeny shows the currently accepted evolutionary history of vertebrates, which are part of the phylum Chordata. How do differences in heart anatomy among these groups support this phylogeny?

- The anatomy of the heart among these groups shows a gradually increasing number of heart chambers across the phylogeny. Fish have a two-chambered heart, amphibians and reptiles have a three-chambered heart, where latter has a partial separation of ventricles. Birds and mammals both have four-chambered hearts.
- The anatomy of the heart among these groups shows a gradually increasing number of heart chambers across the phylogeny. Fish have a two-chambered heart. Amphibians and reptiles have a three-chambered heart where the former has a partial separation of ventricles. Birds and mammals both have four-chambered hearts.
- The anatomy of the heart among these groups shows a gradually increasing number of heart chambers across the phylogeny. Fish and amphibians have a two-chambered heart. Reptiles have a three-chambered heart with a partial separation of ventricles. Birds and mammals both have four-chambered hearts.
- The anatomy of the heart among these groups shows a gradually increasing number of heart chambers across the phylogeny. Fish and amphibians have two-chambered hearts. Reptiles and birds have three-chambered hearts, where the former has a partial separation of ventricles. Mammals have a four-chambered heart.

### 31.3 | Mammalian Heart and Blood Vessels

In this section, you will explore the following questions:

- What is the structure of the heart and how does cardiac muscle differ from other muscles?
- What are the events in the cardiac cycle?
- What is the structure of arteries, veins, and capillaries, and how does blood flow through the body?

#### Connection for AP® Courses

Much of the information in this section is not within the scope for AP®. You likely have studied the pathway of blood through the heart in a previous course, and as a student of biology, you should have some knowledge of this pathway. (No, you do not need to memorize the names of all arteries and veins or the names of the specific valves of the heart.)

The heart is a perfect example of the relationship between structure and function. The four-chambered heart of mammals with its unique cardiac muscle, one-way valves, and vessels is designed to transport vital oxygen ( $O^2$ ) to the body cells and

remove carbon dioxide ( $\text{CO}^2$ ) from tissues. The intricate design of the heart separates blood that is low in  $\text{O}^2$  from blood that is high in  $\text{O}^2$ . This ensures that oxygen-rich blood is delivered to all tissues and cells of the body where it will be used for cellular respiration. Blood returning from the tissues is high in  $\text{CO}^2$  and low in  $\text{O}^2$  will return to the heart and be pumped to the lungs, where gases are exchanged by diffusion at capillary beds.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 4 of the AP<sup>®</sup> Biology Curriculum Framework. The AP<sup>®</sup> Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP<sup>®</sup> Biology course, an inquiry-based laboratory experience, instructional activities, and AP<sup>®</sup> exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>4.18</b> The student is able to use representations and models to analyze how cooperative interactions within organisms promote efficiency in the use of energy and matter. |

The heart is a complex muscle that pumps blood through the three divisions of the circulatory system: the coronary (vessels that serve the heart), pulmonary (heart and lungs), and systemic (systems of the body), as shown in [Figure 31.10](#). Coronary circulation intrinsic to the heart takes blood directly from the main artery (aorta) coming from the heart. For pulmonary and systemic circulation, the heart has to pump blood to the lungs or the rest of the body, respectively. In vertebrates, the lungs are relatively close to the heart in the thoracic cavity. The shorter distance to pump means that the muscle wall on the right side of the heart is not as thick as the left side which must have enough pressure to pump blood all the way to your big toe.

**visual CONNECTION**

The diagram illustrates the mammalian circulatory system with the following labeled components:

- Superior vena cava
- Right atrium
- Aorta
- Pulmonary artery
- Left atrium
- Pulmonary vein
- Right ventricle
- Inferior vena cava
- Systemic circuit

The diagram shows the heart at the center, with the superior vena cava and inferior vena cava bringing deoxygenated blood from the body into the right atrium. The right atrium pumps this blood into the right ventricle. From the right ventricle, the blood is pumped into the pulmonary artery, which branches into the pulmonary circuit. The pulmonary circuit passes through the lungs, where oxygen is taken up by the blood. The oxygenated blood then returns via the pulmonary veins to the left atrium. The left atrium pumps this oxygenated blood into the left ventricle. The left ventricle then pumps the oxygenated blood into the aorta, which distributes it to the rest of the body through the systemic circuit.

**Figure 31.10** The mammalian circulatory system is divided into three circuits: the systemic circuit, the pulmonary circuit, and the coronary circuit. Blood is pumped from veins of the systemic circuit into the right atrium of the heart, then into the right ventricle. Blood then enters the pulmonary circuit, and is oxygenated by the lungs. From the pulmonary circuit, blood re-enters the heart through the left atrium. From the left ventricle, blood re-enters the systemic circuit through the aorta and is distributed to the rest of the body. The coronary circuit, which provides blood to the heart, is not shown.

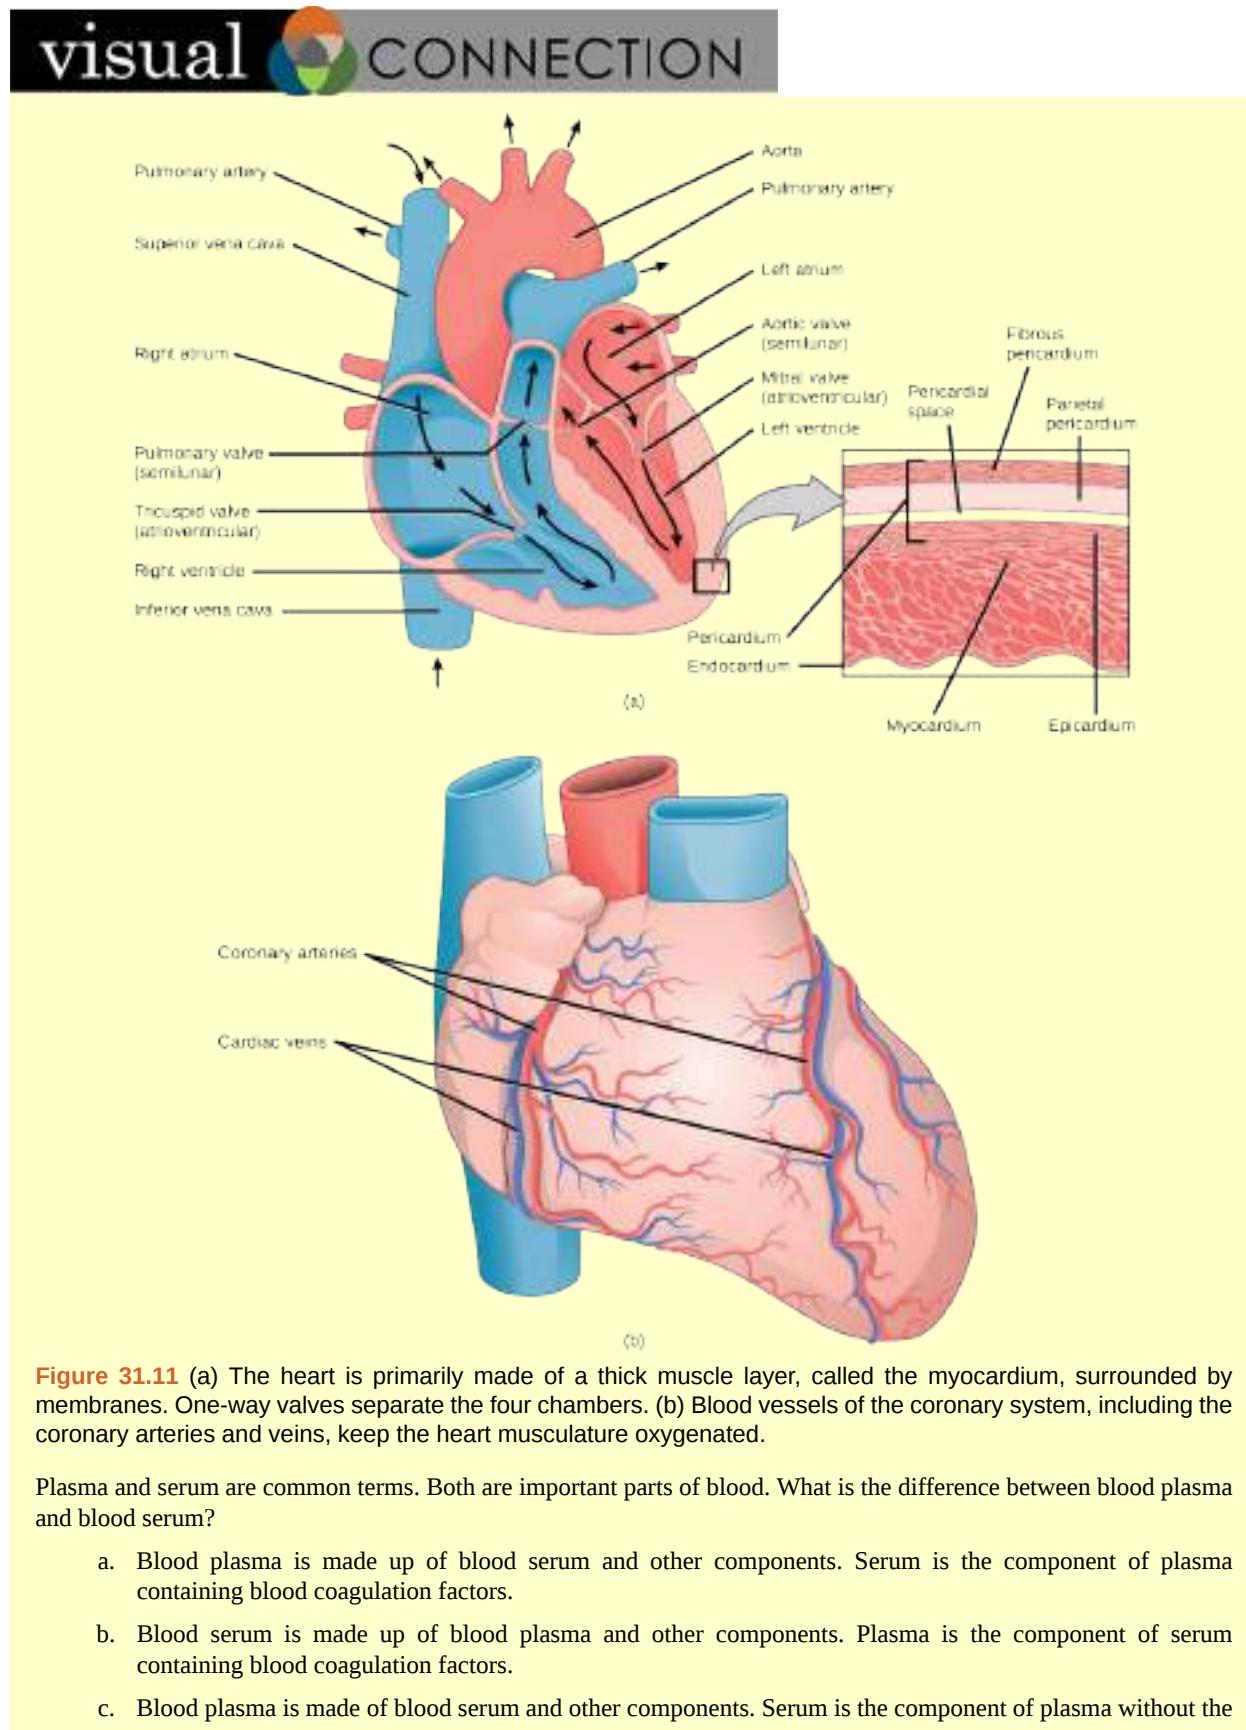

Compare the functions and structures of red and white blood cells.

- Red blood cells lack nuclei at maturity and contain hemoglobin, which distributes oxygen throughout the body. White blood cells are primarily involved in the immune response to identify and target pathogens. They have nuclei and lack hemoglobin
- Red blood cells lack nuclei at maturity and contain hemoglobin, which distributes oxygen throughout the body. White blood cells are primarily involved in the immune response to identify and target pathogens. They lack both nuclei and hemoglobin.
- Red blood cells contain nuclei and hemoglobin, which distributes oxygen throughout the body. White blood cells are primarily involved in the immune response to identify and target pathogens. They lack both nuclei and hemoglobin.
- Red blood cells lack nuclei at maturity and contain hemoglobin, which is involved in the immune response, assisting in identification and targeting of pathogens. White blood cells distribute oxygen throughout the body. They have nuclei and lack hemoglobin.

## Structure of the Heart

The heart muscle is asymmetrical as a result of the distance blood must travel in the pulmonary and systemic circuits. Since the right side of the heart sends blood to the pulmonary circuit it is smaller than the left side which must send blood out to the whole body in the systemic circuit, as shown in **Figure 31.11**. In humans, the heart is about the size of a clenched fist; it is divided into four chambers: two atria and two ventricles. There is one atrium and one ventricle on the right side and one atrium and one ventricle on the left side. The atria are the chambers that receive blood, and the ventricles are the chambers that pump blood. The right atrium receives deoxygenated blood from the **superior vena cava**, which drains blood from the jugular vein that comes from the brain and from the veins that come from the arms, as well as from the **inferior vena cava** which drains blood from the veins that come from the lower organs and the legs. In addition, the right atrium receives blood from the coronary sinus which drains deoxygenated blood from the heart itself. This deoxygenated blood then passes to the

right ventricle through the **atrioventricular valve** or the **tricuspid valve**, a flap of connective tissue that opens in only one direction to prevent the backflow of blood. The valve separating the chambers on the left side of the heart valve is called the bicuspid or mitral valve. After it is filled, the right ventricle pumps the blood through the pulmonary arteries, by-passing the **semilunar valve** (or pulmonic valve) to the lungs for re-oxygenation. After blood passes through the pulmonary arteries, the right semilunar valves close preventing the blood from flowing backwards into the right ventricle. The left atrium then receives the oxygen-rich blood from the lungs via the pulmonary veins. This blood passes through the **bicuspid valve** or mitral valve (the atrioventricular valve on the left side of the heart) to the left ventricle where the blood is pumped out through **aorta**, the major artery of the body, taking oxygenated blood to the organs and muscles of the body. Once blood is pumped out of the left ventricle and into the aorta, the aortic semilunar valve (or aortic valve) closes preventing blood from flowing backward into the left ventricle. This pattern of pumping is referred to as double circulation and is found in all mammals.

**Figure 31.11** (a) The heart is primarily made of a thick muscle layer, called the myocardium, surrounded by membranes. One-way valves separate the four chambers. (b) Blood vessels of the coronary system, including the coronary arteries and veins, keep the heart musculature oxygenated.

Plasma and serum are common terms. Both are important parts of blood. What is the difference between blood plasma and blood serum?

- Blood plasma is made up of blood serum and other components. Serum is the component of plasma containing blood coagulation factors.
- Blood serum is made up of blood plasma and other components. Plasma is the component of serum containing blood coagulation factors.
- Blood plasma is made of blood serum and other components. Serum is the component of plasma without the

blood coagulation factors.

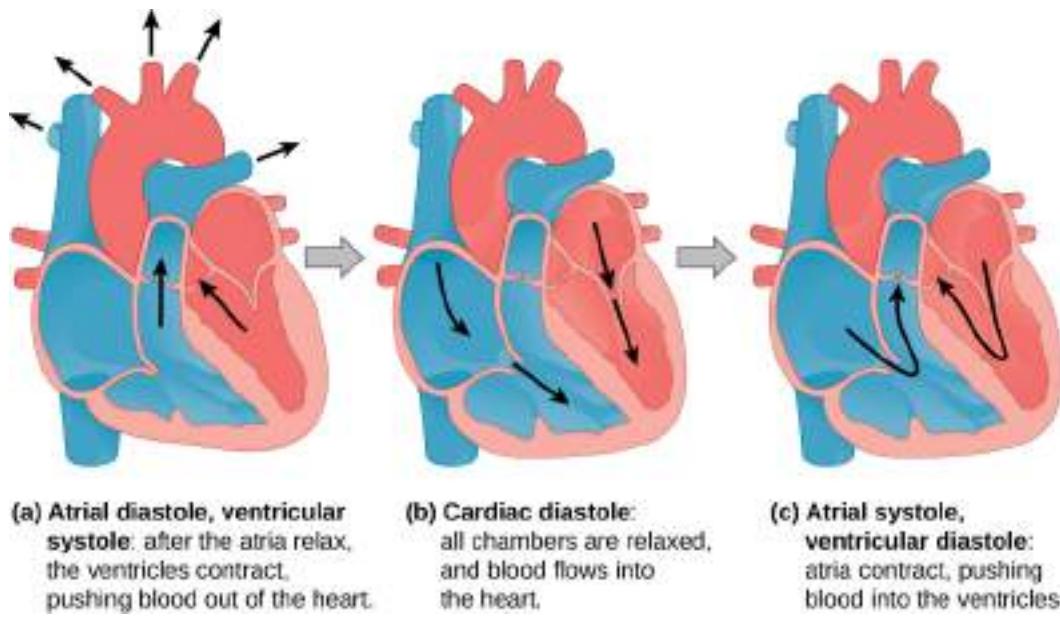

- d. Blood plasma is made up of blood serum and other components. Serum is the component of plasma, which lacks antibodies and hormones.

The heart is composed of three layers; the epicardium, the myocardium, and the endocardium, illustrated in [Figure 31.11](#). The inner wall of the heart has a lining called the **endocardium**. The **myocardium** consists of the heart muscle cells that make up the middle layer and the bulk of the heart wall. The outer layer of cells is called the **epicardium**, of which the second layer is a membranous layered structure called the **pericardium** that surrounds and protects the heart; it allows enough room for vigorous pumping but also keeps the heart in place to reduce friction between the heart and other structures.

The heart has its own blood vessels that supply the heart muscle with blood. The **coronary arteries** branch from the aorta and surround the outer surface of the heart like a crown. They diverge into capillaries where the heart muscle is supplied with oxygen before converging again into the **coronary veins** to take the deoxygenated blood back to the right atrium where the blood will be re-oxygenated through the pulmonary circuit. The heart muscle will die without a steady supply of blood. **Atherosclerosis** is the blockage of an artery by the buildup of fatty plaques. Because of the size (narrow) of the coronary arteries and their function in serving the heart itself, atherosclerosis can be deadly in these arteries. The slowdown of blood flow and subsequent oxygen deprivation that results from atherosclerosis causes severe pain, known as **angina**, and complete blockage of the arteries will cause **myocardial infarction**: the death of cardiac muscle tissue, commonly known as a heart attack.

## The Cardiac Cycle

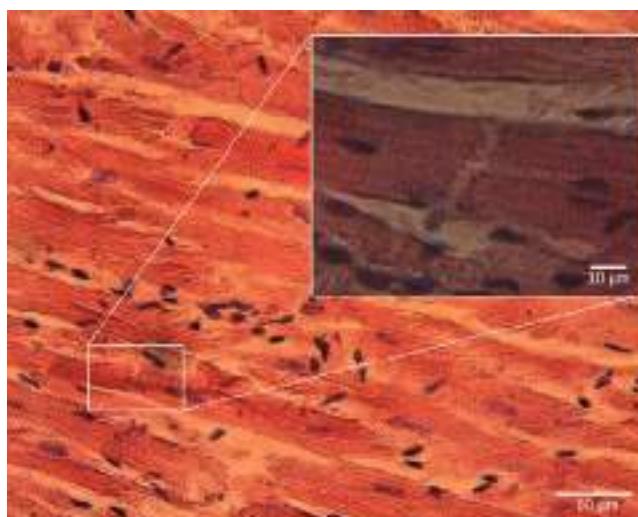

The main purpose of the heart is to pump blood through the body; it does so in a repeating sequence called the cardiac cycle. The **cardiac cycle** is the coordination of the filling and emptying of the heart of blood by electrical signals that cause the heart muscles to contract and relax. The human heart beats over 100,000 times per day. In each cardiac cycle, the heart contracts (**systole**), pushing out the blood and pumping it through the body; this is followed by a relaxation phase (**diastole**), where the heart fills with blood, as illustrated in [Figure 31.12](#). The atria contract at the same time, forcing blood through the atrioventricular valves into the ventricles. Closing of the atrioventricular valves produces a monosyllabic “lup” sound. Following a brief delay, the ventricles contract at the same time forcing blood through the semilunar valves into the aorta and the artery transporting blood to the lungs (via the pulmonary artery). Closing of the semilunar valves produces a monosyllabic “dup” sound.

**Figure 31.12** During (a) atrial diastole, the ventricles contract, forcing blood out of the heart. During (b) cardiac diastole, the heart muscle is relaxed and blood flows into the heart. During (c) atrial systole, the atria contract, pushing blood into the ventricles.

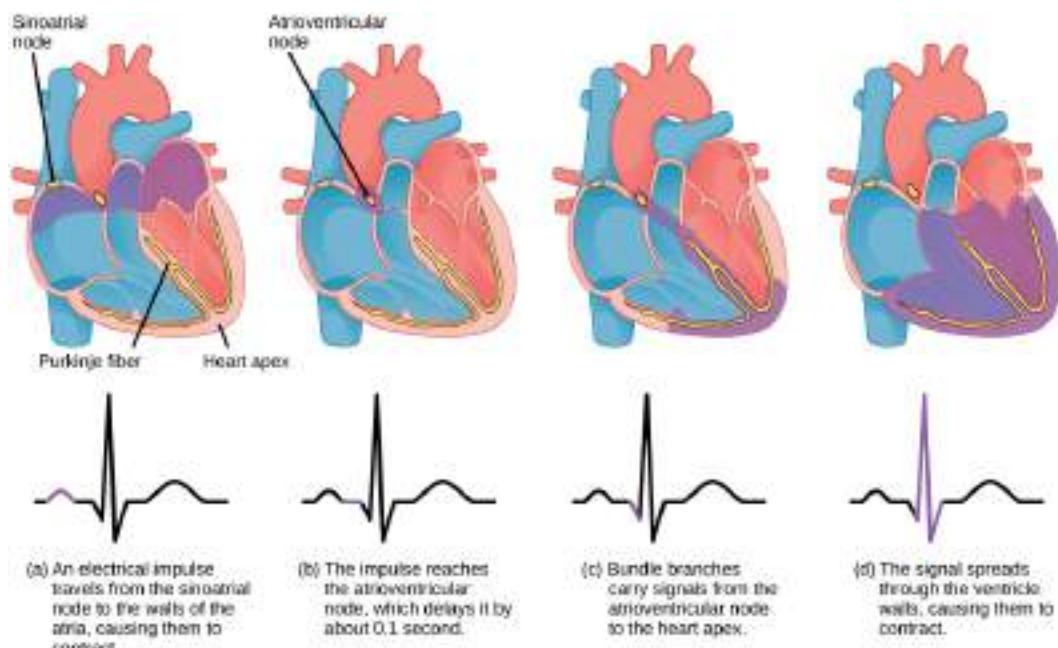

The pumping of the heart is a function of the cardiac muscle cells, or cardiomyocytes, that make up the heart muscle. **Cardiomyocytes**, shown in [Figure 31.13](#), are distinctive muscle cells that are striated like skeletal muscle but pump

rhythmically and involuntarily like smooth muscle; they are connected by intercalated disks exclusive to cardiac muscle. They are self-stimulated for a period of time and isolated cardiomyocytes will beat if given the correct balance of nutrients and electrolytes.

**Figure 31.13** Cardiomyocytes are striated muscle cells found in cardiac tissue. (credit: modification of work by Dr. S. Girod, Anton Becker; scale-bar data from Matt Russell)

The autonomous beating of cardiac muscle cells is regulated by the heart's internal pacemaker that uses electrical signals to time the beating of the heart. The electrical signals and mechanical actions, illustrated in [Figure 31.14](#), are intimately intertwined. The internal pacemaker starts at the **sinoatrial (SA) node**, which is located near the wall of the right atrium. Electrical charges spontaneously pulse from the SA node causing the two atria to contract in unison. The pulse reaches a second node, called the atrioventricular (AV) node, between the right atrium and right ventricle where it pauses for approximately 0.1 second before spreading to the walls of the ventricles. From the AV node, the electrical impulse enters the bundle of His, then to the left and right bundle branches extending through the interventricular septum. Finally, the Purkinje fibers conduct the impulse from the apex of the heart up the ventricular myocardium, and then the ventricles contract. This pause allows the atria to empty completely into the ventricles before the ventricles pump out the blood. The electrical impulses in the heart produce electrical currents that flow through the body and can be measured on the skin using electrodes. This information can be observed as an **electrocardiogram (ECG)**—a recording of the electrical impulses of the cardiac muscle.

**Figure 31.14** The beating of the heart is regulated by an electrical impulse that causes the characteristic reading of an ECG. The signal is initiated at the sinoatrial valve. The signal then (a) spreads to the atria, causing them to contract. The signal is (b) delayed at the atrioventricular node before it is passed on to the (c) heart apex. The delay allows the atria to relax before the (d) ventricles contract. The final part of the ECG cycle prepares the heart for the next beat.

Visit [this site](http://openstaxcollege.org/l/electric_heart) ([http://openstaxcollege.org/l/electric\\_heart](http://openstaxcollege.org/l/electric_heart)) to see the heart's "pacemaker" in action.

Some white blood cells release chemicals upon encountering a pathogen. These chemicals attract other white blood cells to the point of infection. Which of the following statements explains the feedback loop that occurs and predicts what would likely happen if the number of pathogens entering the body increases?

- This is positive feedback. Fewer white blood cells will be attracted to the site as the number of pathogens in the body increases.
- This is negative feedback. Fewer white blood cells will be attracted to the site as the number of pathogens in the body increases.
- This is positive feedback. More white blood cells will be attracted to the site as the number of pathogens in the body increases.
- This is negative feedback. More white blood cells will be attracted to the site as the number of pathogens in the body increases.

## Arteries, Veins, and Capillaries

The blood from the heart is carried through the body by a complex network of blood vessels (Figure 31.16). **Arteries** take blood away from the heart. The main artery is the aorta that branches into major arteries that take blood to different limbs and organs. These major arteries include the carotid artery that takes blood to the brain, the brachial arteries that take blood to the arms, and the thoracic artery that takes blood to the thorax and then into the hepatic, renal, and gastric arteries for the liver, kidney, and stomach, respectively. The iliac artery takes blood to the lower limbs. The major arteries diverge into minor arteries, and then smaller vessels called **arterioles**, to reach more deeply into the muscles and organs of the body.

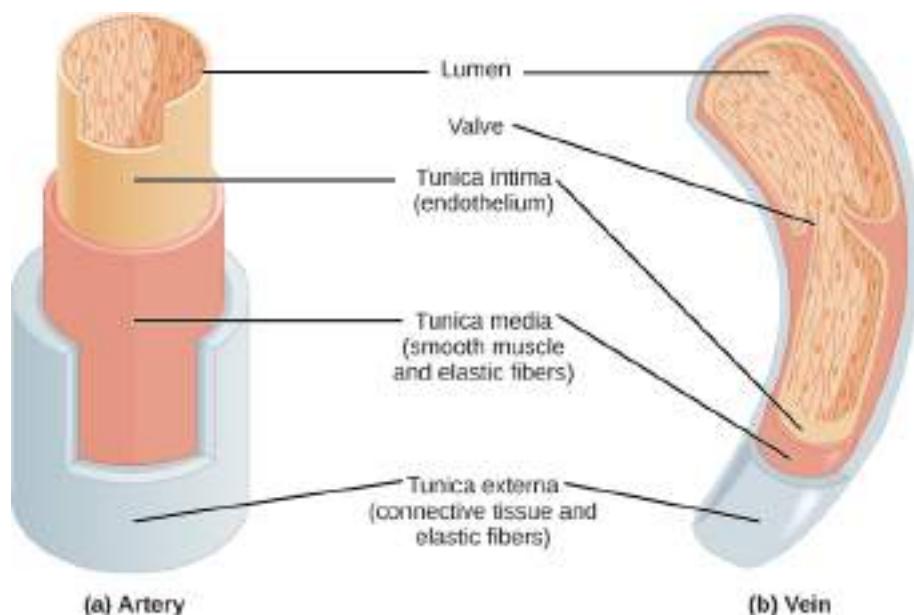

**Figure 31.16** The major human arteries and veins are shown. (credit: modification of work by Mariana Ruiz Villareal)

Arterioles diverge into capillary beds. **Capillary beds** contain a large number (10 to 100) of **capillaries** that branch among the cells and tissues of the body. Capillaries are narrow-diameter tubes that can fit red blood cells through in single file and are the sites for the exchange of nutrients, waste, and oxygen with tissues at the cellular level. Fluid also crosses into the interstitial space from the capillaries. The capillaries converge again into **venules** that connect to minor veins that finally connect to major veins that take blood high in carbon dioxide back to the heart. **Veins** are blood vessels that bring blood back to the heart. The major veins drain blood from the same organs and limbs that the major arteries supply. Fluid is also brought back to the heart via the lymphatic system.

The structure of the different types of blood vessels reflects their function or layers. There are three distinct layers, or tunics, that form the walls of blood vessels (**Figure 31.17**). The first tunic is a smooth, inner lining of endothelial cells that are in contact with the red blood cells. The endothelial tunic is continuous with the endocardium of the heart. In capillaries, this single layer of cells is the location of diffusion of oxygen and carbon dioxide between the endothelial cells and red blood cells, as well as the exchange site via endocytosis and exocytosis. The movement of materials at the site of capillaries is regulated by **vasoconstriction**, narrowing of the blood vessels, and **vasodilation**, widening of the blood vessels; this is important in the overall regulation of blood pressure.

Veins and arteries both have two further tunics that surround the endothelium: the middle tunic is composed of smooth muscle and the outermost layer is connective tissue (collagen and elastic fibers). The elastic connective tissue stretches and supports the blood vessels, and the smooth muscle layer helps regulate blood flow by altering vascular resistance through vasoconstriction and vasodilation. The arteries have thicker smooth muscle and connective tissue than the veins to accommodate the higher pressure and speed of freshly pumped blood. The veins are thinner walled as the pressure and rate of flow are much lower. In addition, veins are structurally different than arteries in that veins have valves to prevent the backflow of blood. Because veins have to work against gravity to get blood back to the heart, contraction of skeletal muscle assists with the flow of blood back to the heart.

**Figure 31.17** Arteries and veins consist of three layers: an outer tunica externa, a middle tunica media, and an inner tunica intima. Capillaries consist of a single layer of epithelial cells, the tunica intima. (credit: modification of work by NCI, NIH)

## science practices CONNECTION for AP<sup>®</sup> Courses

### Activity

Create a representation to track the pathway of a single red blood cell as it travels from a vein in your lower leg to the lung where it delivers carbon dioxide and picks up oxygen. Then describe the pathway it takes through the heart and vessels to return to your lower leg.

### Think About It

How do the events in the cardiac cycle link the circulatory system with the nervous system?

## 31.4 | Blood Flow and Blood Pressure Regulation

In this section, you will explore the following questions:

- How does blood flow through the body?
- How is blood pressure regulated?

### Connection for AP<sup>®</sup> Courses

The information in this section is not within the scope for AP<sup>®</sup>. However, the exchange of oxygen and carbon dioxide at capillary beds is an application of diffusion, a phenomenon we explored in detail in an earlier chapter. In addition, because many persons suffer from high blood pressure, often called the “silent killer,” you might find it informative to know how blood pressure is regulated and why lack of appropriate regulation is detrimental.

**Blood pressure (BP)** is the pressure exerted by blood on the walls of a blood vessel that helps to push blood through the body. Systolic blood pressure measures the amount of pressure that blood exerts on vessels while the heart is beating. The optimal systolic blood pressure is 120 mmHg. Diastolic blood pressure measures the pressure in the vessels between

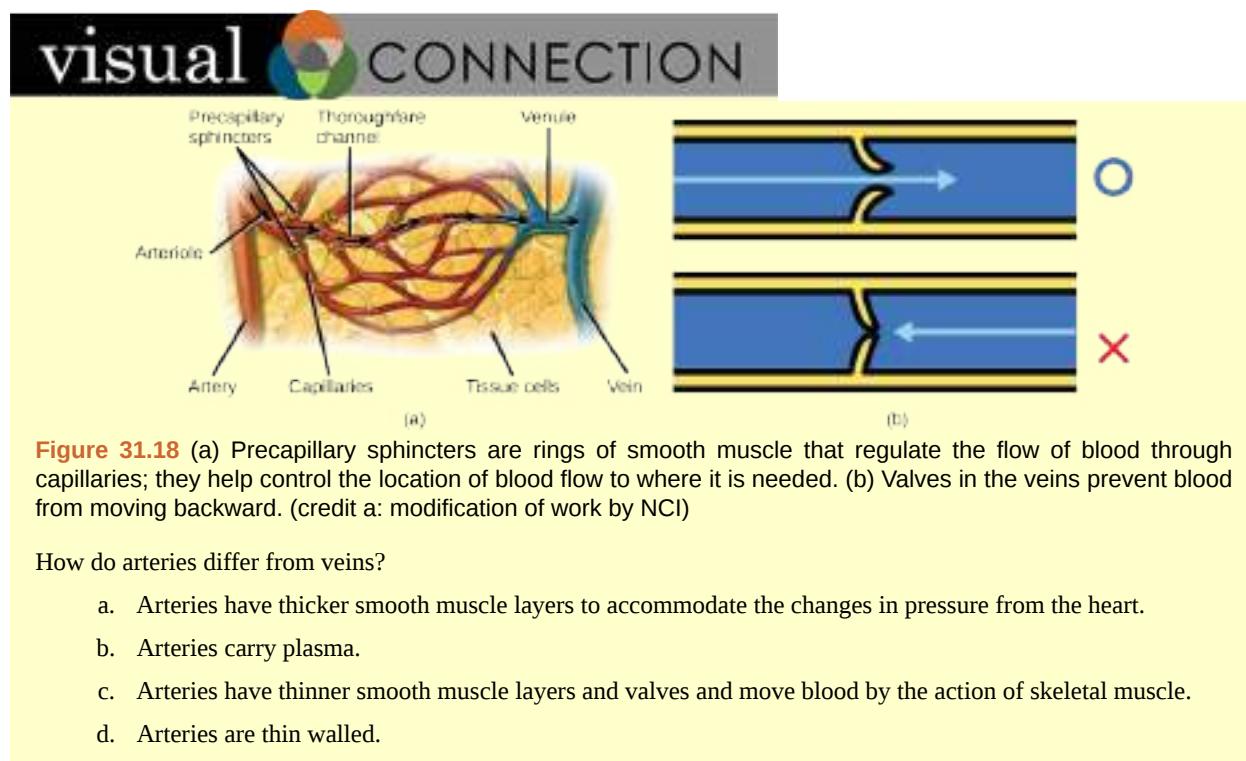

heartbeats. The optimal diastolic blood pressure is 80 mmHg. Many factors can affect blood pressure, such as hormones, stress, exercise, eating, sitting, and standing. Blood flow through the body is regulated by the size of blood vessels, by the action of smooth muscle, by one-way valves, and by the fluid pressure of the blood itself.

## How Blood Flows Through the Body

Blood is pushed through the body by the action of the pumping heart. With each rhythmic pump, blood is pushed under high pressure and velocity away from the heart, initially along the main artery, the aorta. In the aorta, the blood travels at 30 cm/sec. As blood moves into the arteries, arterioles, and ultimately to the capillary beds, the rate of movement slows dramatically to about 0.026 cm/sec, one-thousand times slower than the rate of movement in the aorta. While the diameter of each individual arteriole and capillary is far narrower than the diameter of the aorta, and according to the law of continuity, fluid should travel faster through a narrower diameter tube, the rate is actually slower due to the overall diameter of all the combined capillaries being far greater than the diameter of the individual aorta.

The slow rate of travel through the capillary beds, which reach almost every cell in the body, assists with gas and nutrient exchange and also promotes the diffusion of fluid into the interstitial space. After the blood has passed through the capillary beds to the venules, veins, and finally to the main venae cavae, the rate of flow increases again but is still much slower than the initial rate in the aorta. Blood primarily moves in the veins by the rhythmic movement of smooth muscle in the vessel wall and by the action of the skeletal muscle as the body moves. Because most veins must move blood against the pull of gravity, blood is prevented from flowing backward in the veins by one-way valves. Because skeletal muscle contraction aids in venous blood flow, it is important to get up and move frequently after long periods of sitting so that blood will not pool in the extremities.

Blood flow through the capillary beds is regulated depending on the body's needs and is directed by nerve and hormone signals. For example, after a large meal, most of the blood is diverted to the stomach by vasodilation of vessels of the digestive system and vasoconstriction of other vessels. During exercise, blood is diverted to the skeletal muscles through vasodilation while blood to the digestive system would be lessened through vasoconstriction. The blood entering some capillary beds is controlled by small muscles, called precapillary sphincters, illustrated in [Figure 31.18](#). If the sphincters are open, the blood will flow into the associated branches of the capillary blood. If all of the sphincters are closed, then the blood will flow directly from the arteriole to the venule through the thoroughfare channel (see [Figure 31.18](#)). These muscles allow the body to precisely control when capillary beds receive blood flow. At any given moment only about 5-10% of our capillary beds actually have blood flowing through them.

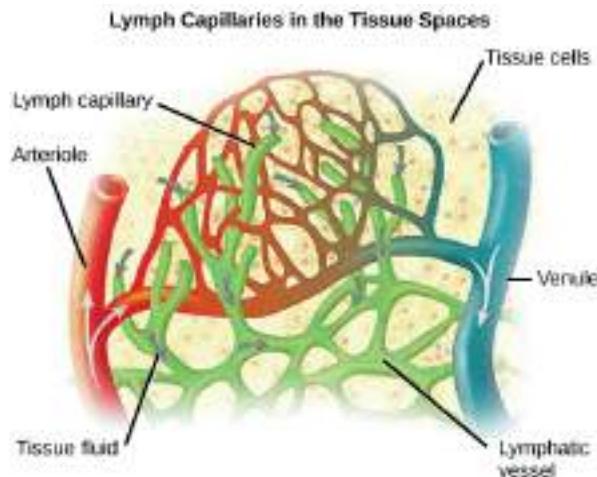

Visit **this site** (<http://openstaxcollege.org/l/circulation>) to see the circulatory system's blood flow.

Capillaries are the smallest of blood vessels. They consist of a \_\_\_\_\_ layer of endothelial cells where diffusion and exchange of materials take place.

- a. single
- b. double
- c. triple
- d. bilateral

Proteins and other large solutes cannot leave the capillaries. The loss of the watery plasma creates a hyperosmotic solution within the capillaries, especially near the venules. This causes about 85% of the plasma that leaves the capillaries to eventually diffuse back into the capillaries near the venules. The remaining 15% of blood plasma drains out from the interstitial fluid into nearby lymphatic vessels (Figure 31.19). The fluid in the lymph is similar in composition to the interstitial fluid. The lymph fluid passes through lymph nodes before it returns to the heart via the vena cava. **Lymph nodes** are specialized organs that filter the lymph by percolation through a maze of connective tissue filled with white blood cells. The white blood cells remove infectious agents, such as bacteria and viruses, to clean the lymph before it returns to the bloodstream. After it is cleaned, the lymph returns to the heart by the action of smooth muscle pumping, skeletal muscle action, and one-way valves joining the returning blood near the junction of the venae cavae entering the right atrium of the heart.

**Figure 31.19** Fluid from the capillaries moves into the interstitial space and lymph capillaries by diffusion down a pressure gradient and also by osmosis. Out of 7,200 liters of fluid pumped by the average heart in a day, over 1,500 liters is filtered. (credit: modification of work by NCI, NIH)

# eVolution CONNECTION

## Vertebrate Diversity in Blood Circulation

Blood circulation has evolved differently in vertebrates and may show variation in different animals for the required amount of pressure, organ and vessel location, and organ size. Animals with long necks and those that live in cold environments have distinct blood pressure adaptations.

Long-necked animals, such as giraffes, need to pump blood upward from the heart against gravity. The blood pressure required from the pumping of the left ventricle would be equivalent to 250 mm Hg (mm Hg = millimeters of mercury, a unit of pressure) to reach the height of a giraffe's head, which is 2.5 meters higher than the heart. However, if checks and balances were not in place, this blood pressure would damage the giraffe's brain, particularly if it was bending down to drink. These checks and balances include valves and feedback mechanisms that reduce the rate of cardiac output. Long-necked dinosaurs such as the sauropods had to pump blood even higher, up to ten meters above the heart. This would have required a blood pressure of more than 600 mm Hg, which could only have been achieved by an enormous heart. Evidence for such an enormous heart does not exist and mechanisms to reduce the blood pressure required include the slowing of metabolism as these animals grew larger. It is likely that they did not routinely feed on tree tops but grazed on the ground.

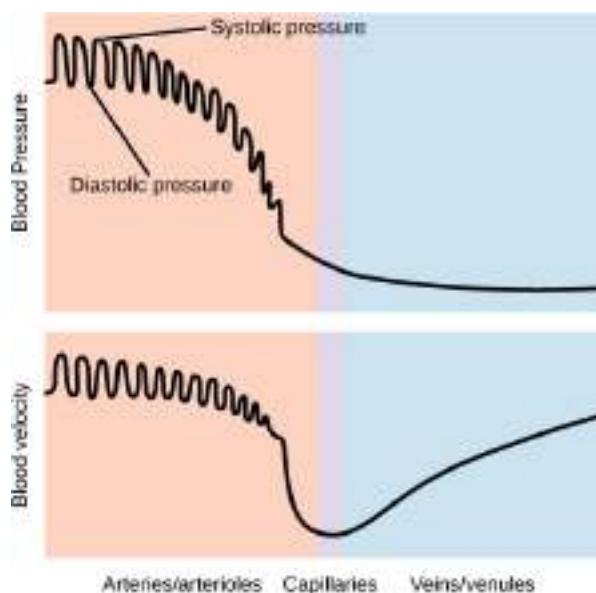

Living in cold water, whales need to maintain the temperature in their blood. This is achieved by the veins and arteries being close together so that heat exchange can occur. This mechanism is called a countercurrent heat exchanger. The blood vessels and the whole body are also protected by thick layers of blubber to prevent heat loss. In land animals that live in cold environments, thick fur and hibernation are used to retain heat and slow metabolism.

The heart is asymmetrical in shape. How does the way that the heart functions determine this feature of the heart's structure?

- a. The right and left sides of the heart are responsible for pumping blood to separate regions of the body covering same distances.
- b. The right side of heart sends blood to the lungs to be deoxygenated in the pulmonary circuit, while the left side sends oxygenated blood to the rest of the body in the systemic circuit.
- c. The left side of heart sends blood to the lungs to be oxygenated in the pulmonary circuit, while the right side sends blood to the rest of the body in the systemic circuit.
- d. The right side of heart sends blood to the lungs to be oxygenated in the pulmonary circuit, while the left side sends blood to the rest of the body in the systemic circuit.

## Blood Pressure

The pressure of the blood flow in the body is produced by the hydrostatic pressure of the fluid (blood) against the walls of the blood vessels. Fluid will move from areas of high to low hydrostatic pressures. In the arteries, the hydrostatic pressure near the heart is very high and blood flows to the arterioles where the rate of flow is slowed by the narrow openings of the arterioles. During systole, when new blood is entering the arteries, the artery walls stretch to accommodate the increase of pressure of the extra blood; during diastole, the walls return to normal because of their elastic properties. The blood pressure of the systole phase and the diastole phase, graphed in **Figure 31.20**, gives the two pressure readings for blood pressure. For example, 120/80 indicates a reading of 120 mm Hg during the systole and 80 mm Hg during diastole. Throughout the cardiac cycle, the blood continues to empty into the arterioles at a relatively even rate. This resistance to blood flow is called **peripheral resistance**.

**Figure 31.20** Blood pressure is related to the blood velocity in the arteries and arterioles. In the capillaries and veins, the blood pressure continues to decrease but velocity increases.

## Blood Pressure Regulation

Cardiac output is the volume of blood pumped by the heart in one minute. It is calculated by multiplying the number of heart contractions that occur per minute (heart rate) times the **stroke volume** (the volume of blood pumped into the aorta per contraction of the left ventricle). Therefore, cardiac output can be increased by increasing heart rate, as when exercising. However, cardiac output can also be increased by increasing stroke volume, such as if the heart contracts with greater strength. Stroke volume can also be increased by speeding blood circulation through the body so that more blood enters the heart between contractions. During heavy exertion, the blood vessels relax and increase in diameter, offsetting the increased heart rate and ensuring adequate oxygenated blood gets to the muscles. Stress triggers a decrease in the diameter of the blood vessels, consequently increasing blood pressure. These changes can also be caused by nerve signals or hormones, and even standing up or lying down can have a great effect on blood pressure.

## KEY TERMS

**angina** pain caused by partial blockage of the coronary arteries by the buildup of plaque and lack of oxygen to the heart muscle

**aorta** major artery of the body that takes blood away from the heart

**arteriole** small vessel that connects an artery to a capillary bed

**artery** blood vessel that takes blood away from the heart

**atherosclerosis** buildup of fatty plaques in the coronary arteries in the heart

**atrioventricular valve** one-way membranous flap of connective tissue between the atrium and the ventricle in the right side of the heart; also known as tricuspid valve

**atrium** (plural: atria) chamber of the heart that receives blood from the veins and sends blood to the ventricles

**bicuspid valve** (also, mitral valve; left atrioventricular valve) one-way membranous flap between the atrium and the ventricle in the left side of the heart

**blood pressure (BP)** pressure of blood in the arteries that helps to push blood through the body

**capillary** smallest blood vessel that allows the passage of individual blood cells and the site of diffusion of oxygen and nutrient exchange

**capillary bed** large number of capillaries that converge to take blood to a particular organ or tissue

**cardiac cycle** filling and emptying the heart of blood by electrical signals that cause the heart muscles to contract and relax

**cardiac output** the volume of blood pumped by the heart in one minute as a product of heart rate multiplied by stroke volume

**cardiomyocyte** specialized heart muscle cell that is striated but contracts involuntarily like smooth muscle

**closed circulatory system** system in which the blood is separated from the bodily interstitial fluid and contained in blood vessels

**coronary artery** vessel that supplies the heart tissue with blood

**coronary vein** vessel that takes blood away from the heart tissue back to the chambers in the heart

**diastole** relaxation phase of the cardiac cycle when the heart is relaxed and the ventricles are filling with blood

**double circulation** flow of blood in two circuits: the pulmonary circuit through the lungs and the systemic circuit through the organs and body

**electrocardiogram (ECG)** recording of the electrical impulses of the cardiac muscle

**endocardium** innermost layer of tissue in the heart

**epicardium** outermost tissue layer of the heart

**gill circulation** circulatory system that is specific to animals with gills for gas exchange; the blood flows through the gills for oxygenation

**hemocoel** cavity into which blood is pumped in an open circulatory system

**hemolymph** mixture of blood and interstitial fluid that is found in insects and other arthropods as well as most mollusks

**inferior vena cava** drains blood from the veins that come from the lower organs and the legs

**interstitial fluid** fluid between cells

**lymph node** specialized organ that contains a large number of macrophages that clean the lymph before the fluid is returned to the heart

**myocardial infarction** (also, heart attack) complete blockage of the coronary arteries and death of the cardiac muscle tissue

**myocardium** heart muscle cells that make up the middle layer and the bulk of the heart wall

**open circulatory system** system in which the blood is mixed with interstitial fluid and directly covers the organs

**ostium** (plural: ostia) holes between blood vessels that allow the movement of hemolymph through the body of insects, arthropods, and mollusks with open circulatory systems

**pericardium** membrane layer protecting the heart; also part of the epicardium

**peripheral resistance** resistance of the artery and blood vessel walls to the pressure placed on them by the force of the heart pumping

**plasma** liquid component of blood that is left after the cells are removed

**platelet** (also, thrombocyte) small cellular fragment that collects at wounds, cross-reacts with clotting factors, and forms a plug to prevent blood loss

**precapillary sphincter** small muscle that controls blood circulation in the capillary beds

**pulmocutaneous circulation** circulatory system in amphibians; the flow of blood to the lungs and the moist skin for gas exchange

**pulmonary circulation** flow of blood away from the heart through the lungs where oxygenation occurs and then returns to the heart again

**red blood cell** small (7–8  $\mu\text{m}$ ) biconcave cell without mitochondria (and in mammals without nuclei) that is packed with hemoglobin, giving the cell its red color; transports oxygen through the body

**semilunar valve** membranous flap of connective tissue between the aorta and a ventricle of the heart (the aortic or pulmonary semilunar valves)

**serum** plasma without the coagulation factors

**sinoatrial (SA) node** the heart's internal pacemaker; located near the wall of the right atrium

**stroke volume** the volume of blood pumped into the aorta per contraction of the left ventricle

**superior vena cava** drains blood from the jugular vein that comes from the brain and from the veins that come from the arms

**systemic circulation** flow of blood away from the heart to the brain, liver, kidneys, stomach, and other organs, the limbs, and the muscles of the body, and then the return of this blood to the heart

**systole** contraction phase of cardiac cycle when the ventricles are pumping blood into the arteries

**tricuspid valve** one-way membranous flap of connective tissue between the atrium and the ventricle in the right side of the heart; also known as atrioventricular valve

**unidirectional circulation** flow of blood in a single circuit; occurs in fish where the blood flows through the gills, then past the organs and the rest of the body, before returning to the heart

**vasoconstriction** narrowing of a blood vessel

**vasodilation** widening of a blood vessel

**vein** blood vessel that brings blood back to the heart

**vena cava** major vein of the body returning blood from the upper and lower parts of the body; see the superior vena cava and inferior vena cava

**ventricle** (heart) large inferior chamber of the heart that pumps blood into arteries

**venule** blood vessel that connects a capillary bed to a vein

**white blood cell** large (30  $\mu\text{m}$ ) cell with nuclei of which there are many types with different roles including the protection of the body from viruses and bacteria, and cleaning up dead cells and other waste

## CHAPTER SUMMARY

### 31.1 Overview of the Circulatory System

In most animals, the circulatory system is used to transport blood through the body. Some primitive animals use diffusion for the exchange of water, nutrients, and gases. However, complex organisms use the circulatory system to carry gases, nutrients, and waste through the body. Circulatory systems may be open (mixed with the interstitial fluid) or closed (separated from the interstitial fluid). Closed circulatory systems are a characteristic of vertebrates; however, there are significant differences in the structure of the heart and the circulation of blood between the different vertebrate groups due to adaptions during evolution and associated differences in anatomy. Fish have a two-chambered heart with unidirectional circulation. Amphibians have a three-chambered heart, which has some mixing of the blood, and they have double circulation. Most non-avian reptiles have a three-chambered heart, but have little mixing of the blood; they have double circulation. Mammals and birds have a four-chambered heart with no mixing of the blood and double circulation.

### 31.2 Components of the Blood

Specific components of the blood include red blood cells, white blood cells, platelets, and the plasma, which contains coagulation factors and serum. Blood is important for regulation of the body's pH, temperature, osmotic pressure, the circulation of nutrients and removal of waste, the distribution of hormones from endocrine glands, and the elimination of excess heat; it also contains components for blood clotting. Red blood cells are specialized cells that contain hemoglobin and circulate through the body delivering oxygen to cells. White blood cells are involved in the immune response to identify and target invading bacteria, viruses, and other foreign organisms; they also recycle waste components, such as old red blood cells. Platelets and blood clotting factors cause the change of the soluble protein fibrinogen to the insoluble protein fibrin at a wound site forming a plug. Plasma consists of 90 percent water along with various substances, such as coagulation factors and antibodies. The serum is the plasma component of the blood without the coagulation factors.

### 31.3 Mammalian Heart and Blood Vessels

The heart muscle pumps blood through three divisions of the circulatory system: coronary, pulmonary, and systemic. There is one atrium and one ventricle on the right side and one atrium and one ventricle on the left side. The pumping of the heart is a function of cardiomyocytes, distinctive muscle cells that are striated like skeletal muscle but pump rhythmically and involuntarily like smooth muscle. The internal pacemaker starts at the sinoatrial node, which is located near the wall of the right atrium. Electrical charges pulse from the SA node causing the two atria to contract in unison; then the pulse reaches the atrioventricular node between the right atrium and right ventricle. A pause in the electric signal allows the atria to empty completely into the ventricles before the ventricles pump out the blood. The blood from the heart is carried through the body by a complex network of blood vessels; arteries take blood away from the heart, and veins bring blood back to the heart.

### 31.4 Blood Flow and Blood Pressure Regulation

Blood primarily moves through the body by the rhythmic movement of smooth muscle in the vessel wall and by the action of the skeletal muscle as the body moves. Blood is prevented from flowing backward in the veins by one-way valves. Blood flow through the capillary beds is controlled by precapillary sphincters to increase and decrease flow depending on the body's needs and is directed by nerve and hormone signals. Lymph vessels take fluid that has leaked out of the blood to the lymph nodes where it is cleaned before returning to the heart. During systole, blood enters the arteries, and the artery walls stretch to accommodate the extra blood. During diastole, the artery walls return to normal. The blood pressure of the systole phase and the diastole phase gives the two pressure readings for blood pressure.

## REVIEW QUESTIONS

1. Which of the following organisms has an open circulatory system?
  - a. a cat
  - b. a bee
  - c. a human
  - d. a bird
  
2. What is an advantage of an open circulatory system?
  - a. It uses less metabolic energy.
  - b. It enables an organism to move faster.
  - c. It is a more efficient way to move gases, nutrients, and waste around an organism's body.
  - d. It allows organisms to grow larger.
  
3. Which of the following statements about circulatory systems is false?
  - a. In closed circulatory systems, blood flows through vessels that are separate from the interstitial fluid of the body.
  - b. The earthworm has a closed circulatory system.
  - c. In an open circulatory system, hemolymph empties into the body cavity.
  - d. Lobsters are organisms that have closed circulatory systems.
  
4. Which of the following statements best defines the open circulatory system?
  - a. In an open circulatory system, blood mixes with interstitial fluid in the hemocoel.
  - b. In an open circulatory system, the blood is separated from the bodily interstitial fluid and contained blood vessels.
  - c. Blood circulates unidirectionally from the heart around systemic circulatory root.
  - d. An open circulatory system uses more energy than a closed circulatory system.
  
5. A simple organism such as a jellyfish uses \_\_\_\_\_ to exchange gases and nutrients with their surrounding environment.
  - a. blood
  - b. diffusion
  - c. atria
  - d. blood vessels
  
6. Fish and birds have closed circulation. They both have a systemic circulatory system, which delivers blood from the heart and out to the organs of the body. Birds differ from fish in that they have a circuit that leads through the lungs and back to the heart. What is this called?

- a. pulmonary circulatory circuit
- b. gill circulatory circuit
- c. pulmocutaneous circulatory circuit
- d. lymph circulatory circuit

7.

| Organism | Method of circulation                  |
|----------|----------------------------------------|
| A        | Closed 2-chambered heart               |
| B        | Closed within 4-chambered heart        |
| C        | Open with some closed arterial vessels |
| D        | Closed within 3-chambered heart        |
| E        | Open within hemocoel                   |
| F        | Diffusion                              |

A student is attempting to reorganize some preserved animals in the biology lab that have lost their labels. The student notices there are some notes on each jar, providing information on each animal's classification. The student labels the unknown animals A-F and enters each animal's circulatory system characteristics in a table. If the student wished to create a phylogeny of organisms A through F, which organism would likely be on the extreme right of the phylogenetic tree?

- a. organism A
- b. organism B
- c. organism E
- d. organism F

8.

| Organism | Method of circulation                  |
|----------|----------------------------------------|
| A        | Closed 2-chambered heart               |
| B        | Closed within 4-chambered heart        |
| C        | Open with some closed arterial vessels |
| D        | Closed within 3-chambered heart        |
| E        | Open within hemocoel                   |
| F        | Diffusion                              |

A student is attempting to reorganize some preserved animals in the biology lab that have lost their labels. The student notices there are some notes on each jar, providing information on each animal's classification. The student labels the unknown animals A-F and enters each animal's circulatory system characteristics in a table. If the student wished to create a phylogeny of organisms A through F, in what order would the organisms most likely appear on the tree, from left to right, and why?

- a. The order would be F, E, C, A, B, D as the general trend in circulatory system evolution is toward increasingly closed systems.
- b. The order would be B, D, A, C, E, F as the general trend in circulatory system evolution is toward increasingly open systems.
- c. The order would be F, E, C, A, D, B as the general trend in circulatory system evolution is toward increasingly closed systems.
- d. The order would be F, E, C, D, B, A as the general trend in circulatory system evolution is toward increasingly open systems.

9. Differences in human blood types show how genetic differences have evolved over time, affecting red blood cell structure. What is the basis for blood type classifications?

- a. It is based on antigens made of carbohydrates, specifically glycoside and N-acetylglucosamine, found on the surface of red blood cells.
- b. It is based on antigens made of proteins, specifically glycolipids and glycoproteins, found on the surface of red blood cells.
- c. It is based on antigens made of proteins, specifically peripheral and integral proteins, found on the surface of the red blood cell.
- d. It is based on antigens made of lipids, specifically glycerophospholipids, found on the surface of red blood cells.

10. If a person has blood type AB/Rh-, what antibodies will be found in the blood?

- a. A antibodies
- b. A antibodies and B antibodies
- c. Rh antibodies
- d. B antibodies

11. Components found in human blood include white blood cells, red blood cells, and \_\_\_\_\_.

- a. platelets
- b. ostia
- c. hemolymph
- d. cardiomyocytes

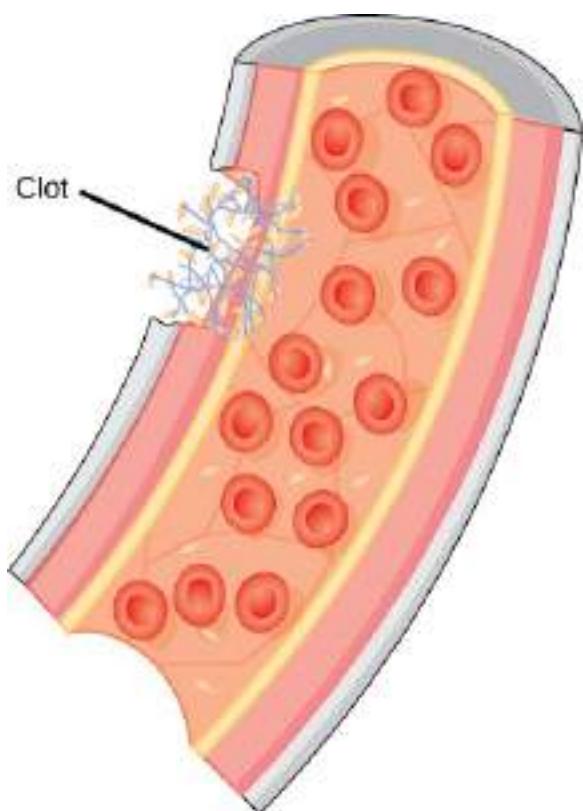

12. Up to four components can be derived from donated blood. One of those components is plasma. Which of the following is not a basic component of plasma?

- a. water
- b. proteins
- c. salts
- d. red blood cells

13. Many platelets converge and stick together at a wound site, eventually forming a platelet plug, also called a fibrin clot. Platelets continue to arrive at the wound site until the plug is completely formed. Describe the feedback mechanisms taking place and predict what would likely happen if part of the platelet plug broke away before the wound was healed.

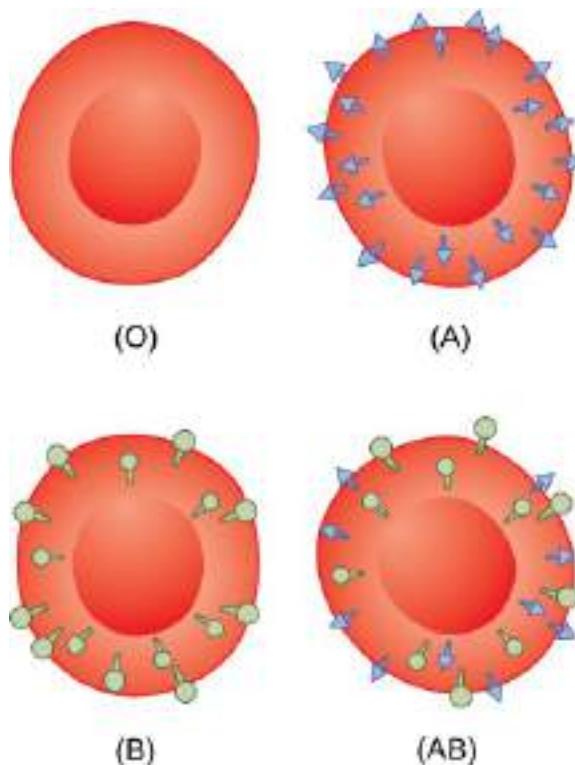

- a. A positive feedback loop, which would restart if part of the platelet plug broke away, calling more platelets to the site to repair the broken plug.
- b. A negative feedback loop, which would restart if part of the platelet plug broke away, calling more platelets to the site to repair the broken plug.
- c. A positive feedback loop, which would not restart if part of the platelet plug broke away.
- d. A negative feedback loop, which would not restart if part of the platelet plug broke away.

14.

The diagram shows a fibrin clot forming within a blood vessel. What constituents of the blood interact to form the clot?

- red blood cells, serum, and vitamin K
  - fibrin, megakaryocytes and blood proteins
  - granulocytes, platelets and red blood cells
  - platelets, fibrinogen, and clotting factors
- 15.**
- Antigens, which identify the red blood cells as part of the body, as opposed to foreign red blood cells, which may be attacked by antibodies within the blood.
  - Glycoproteins, which identify the red blood cells as part of the body, as opposed to foreign red blood cells, which may be attacked by antigens within the blood.
  - Glycoproteins which identify the red blood cells as part of the body, as opposed to foreign red blood cells, which may be attacked by antibodies within the blood.
  - Antibodies which identify the red blood cells as part of the body, as opposed to foreign red blood cells, causing neutralization of the foreign cells.
- 16.** Your heart is a pump that circulates blood and oxygen around your body. Which of the following statements about the circulatory system is false?
- Blood in the pulmonary veins is deoxygenated.
  - Blood in the inferior vena cava is deoxygenated.
  - Blood in the pulmonary artery is deoxygenated.
  - Blood in the aorta is oxygenated.
- 17.** Which of the following statements about the heart is false?

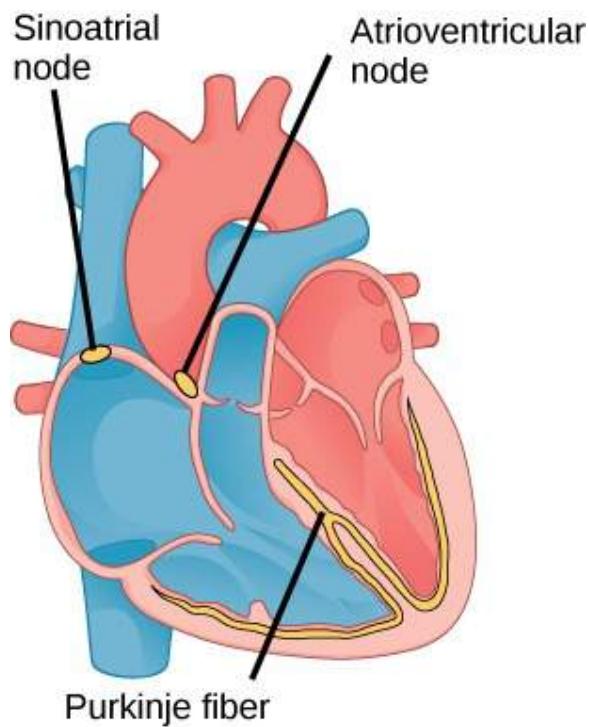

The diagram models the four different types of red blood cells in humans. Describe what is represented by the colored shapes on the surface of the cells and explain their function.

- a. The mitral valve separates the left ventricle from the left atrium.
  - b. Blood travels through the bicuspid valve to the left atrium.
  - c. Both the aortic and the pulmonary valves are semilunar valves.
  - d. The mitral valve is an atrioventricular valve.
- 18.** In a healthy heart, a heartbeat begins within an electrical signal from which part of the heart?
- a. bundle of His
  - b. atrioventricular (AV) node
  - c. sinoatrial (SA) node
  - d. atrial diastole
- 19.** Describe the cardiac cycle and explain what drives it.
- a. The heart contracts to pump blood through the body during systole and is filled with blood during diastole. An electrical charge spontaneously pulses from SA node causing two atria to contract. The pulse reaches AV node where it pauses before spreading to the walls of the ventricles. It enters the bundle of His, then to left and right bundle branches extending through the interventricular septum. Purkinje fibers conduct impulse from the apex up the ventricular myocardium, causing the ventricles to contract. This pause allows the atria to empty their contents into the ventricles before the ventricles pump out the blood.
  - b. The heart contracts to pump blood through the body during diastole and is filled with blood during systole. An electrical charge spontaneously pulses from SA node causing two atria to contract. The pulse reaches AV node where it pauses before spreading to the walls of the ventricles. It enters the bundle of His, then to left and right bundle branches extending through the interventricular septum. Purkinje fibers conduct the impulse from the apex up the ventricular myocardium, causing the ventricles to contract. This pause allows the atria to empty their contents into the ventricles before the ventricles pump out the blood.
  - c. The heart contracts to pump blood through the body during systole and is filled with blood during diastole. An electrical charge spontaneously pulses from AV node causing two atria to contract. The pulse reaches SA node where it pauses before spreading to the walls of the ventricles. It enters the bundle of His, then to left and right bundle branches extending through the interventricular septum. Purkinje fibers conduct impulse from the apex up the ventricular myocardium, causing the ventricles to contract. This pause allows the atria to empty their contents into the ventricles before the ventricles pump out the blood.
  - d. The heart contracts to pump blood through the body during systole and is filled with blood during diastole. An electrical charge spontaneously pulses from SA node causing two atria to contract. The pulse reaches AV node where it pauses before spreading to the walls of the ventricles. It enters the Purkinje fibers, then to left and right bundle branches extending through the interventricular septum. The bundle of His conduct impulse from the apex up the ventricular myocardium, causing the ventricles to contract. This pause allows the atria to empty their contents into the ventricles before the ventricles pump out the blood.
- 20.** Compare and contrast veins and arteries.

- a. Both veins and arteries have three distinct layers. Veins take blood away from the heart and arteries bring blood back to the heart.
- b. Both veins and arteries have three distinct layers. Arteries take blood away from the heart and veins bring blood back to the heart.
- c. Both veins and arteries have valves to prevent the backflow of blood. Arteries take blood away from the heart and veins bring blood back to the heart.
- d. Both veins and arteries have valves to prevent the backflow of blood. Veins take blood away from the heart and arteries bring blood back to the heart.

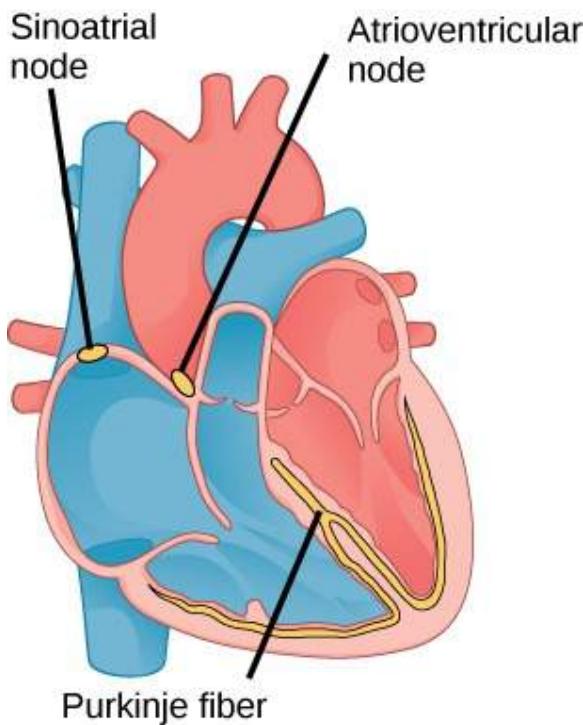

21.

The diagram below shows the neural structures that control and coordinate the beating of the heart. How would the cardiac cycle be affected if neural signals were blocked within the Purkinje fiber?

- a. The atria and ventricles would contract at the same time.
- b. The ventricles would not contract.
- c. The atria would contract first, followed by the ventricles.
- d. Only the left atrium would contract.

22.

The diagram shows the neural structures that control and coordinate the beating of the heart. Explain fully how the cardiac cycle would be affected if the signal was blocked at the atrioventricular node and why.

- a. The atria would contract, but the ventricles would not, because the atrioventricular node passes signals to the Purkinje fibers, which allow the ventricles to contract.
- b. The ventricles would contract, but the atria would not, because the atrioventricular node passes the signal to the Purkinje fibers, which allow the ventricles to contract.
- c. The atria would contract, but the ventricles would not, because the atrioventricular node passes the signal to the Purkinje fibers, which allow the atria to contract.
- d. The ventricles would contract, but the atria would not, because the atrioventricular node passes the signal to the Purkinje fibers, which causes the atria to contract.

## CRITICAL THINKING QUESTIONS

23. Define a closed circulatory system and compare the differences in heart structure for animals with closed

circulatory systems.

- a. A closed circulatory system is a system in which the blood mixes with the interstitial fluid. Fish have a two-chambered heart. Amphibians and reptiles have a three-chambered heart, but the latter has little mixing of blood. Mammals and birds have a four-chambered heart and double circulation.
- b. A closed circulatory system is a system in which blood is separate from the interstitial fluid. Fish have a two-chambered heart. Amphibians and reptiles have a three-chambered heart, but the latter has little mixing of blood. Mammals and birds have a four-chambered heart and double circulation.
- c. A closed circulatory system is a system in which blood is separate from the interstitial fluid. Amphibians have a two-chambered heart. Fishes and reptiles have a three-chambered heart, but the latter has little mixing of blood. Mammals and birds have a four-chambered heart and double circulation.
- d. A closed circulatory system is a system in which blood mixes with the interstitial fluid. Amphibians have a two-chambered heart. Fishes and reptiles have a three-chambered heart, but the latter has little mixing of blood. Mammals and birds have a four-chambered heart and double circulation.

**24.** A circulatory system is the main method for transporting gases and nutrients throughout the body. Explain what happens in a closed circulatory system and compare a closed circulatory system to an open closed circulatory system.

- a. Blood in closed circulatory system is present inside blood vessels and circulates unidirectional from the heart, around the systemic circulatory route, then returns to the heart. It is less controlled and structured than an open circulatory system, but nutrients and waste products are transported more efficiently.
- b. Blood in closed circulatory system is not enclosed in blood vessels, but is pumped into a hemocoel, which circulates around the organs, then reenters the heart through ostia. It is more structured, controlled, and nutrients and waste products are transported more efficiently.
- c. Blood in closed circulatory system is not enclosed in blood vessels, but is pumped into a hemocoel, which circulates around the organs, then reenters the heart through ostia. It is less controlled and structured than an open circulatory system, but nutrients and waste products are transported more efficiently.
- d. Blood in a closed circulatory system is present inside blood vessels, circulates unidirectional from heart around the systemic circulatory route, and then returns to the heart. It is more structured, controlled, and nutrients and waste products are transported more efficiently than in open circulatory system.

**25.** What is one advantage of a four chambered heart over a three chambered heart?

- a. Oxygenated blood carried by the right side of the heart is completely separated from the left side carrying deoxygenated blood, which assists in more efficient movement of oxygen around the body and aids in allowing the body to quickly move when needed.
- b. A four-chambered heart keeps oxygenated and deoxygenated blood separated and has double circulation whereas a three-chambered heart has a single circulation. This assists in more efficient movement of oxygen around the body.
- c. Oxygenated and deoxygenated blood are kept separate in a four-chambered heart, which assists in more efficient movement of carbon dioxide around the body.
- d. Oxygenated and deoxygenated blood are kept separate in a four-chambered heart, which assists in more efficient movement of oxygen around the body and aids in allowing the body to move quickly when needed.

**26.** What are red blood cells also known as?

- a. lymphocytes
- b. monocytes
- c. erythrocytes
- d. basophils

27. How does the structure of red blood cells allow them to deliver oxygen to the cells of the body?

- a. Their size and shape allow them to carry and transfer oxygen.
- b. Their disc shape contains many small vesicles that allow them to carry and transfer oxygen.
- c. They have nuclei and do not contain hemoglobin.
- d. They contain coagulation factors and antibodies.

28. Which of the following best describes plasma?

- a. It is a protein synthesized in the liver.
- b. It is a liquid that contains only lipids and antibodies.
- c. It is a blood component that is separated by spinning blood.
- d. It is an antibody produced in the mucosal lining.

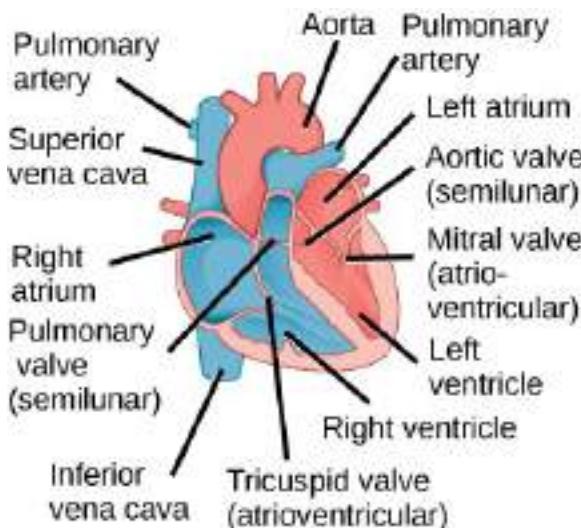

29. What is the heart's internal pacemaker?

- a. An internal implant sends an electrical impulse through the heart.
- b. It is an electrical impulse that starts in cardiac muscle cells at the sinoatrial node.
- c. It is the excitation of cardiac muscle cells at the atrioventricular node followed by the sinoatrial node.
- d. It starts in the aorta.

30. Cardiomyocytes are similar to skeletal muscle because \_\_\_\_\_.

- a. they beat involuntarily
- b. they are attached to bones
- c. they pulse rhythmically
- d. they are striated

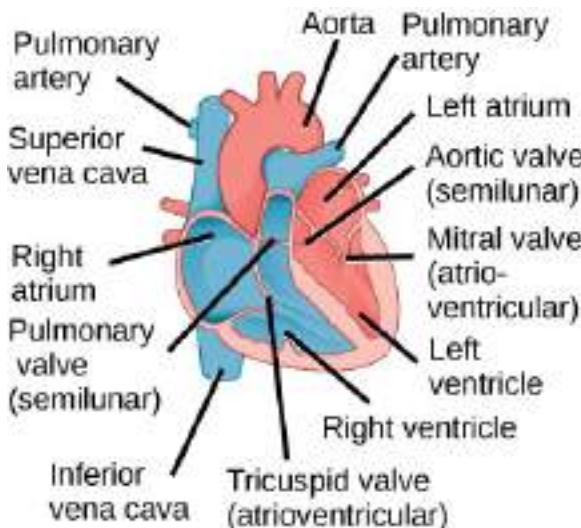

31.

The diagram shows the internal anatomy of the heart. How would blood circulation beyond the heart be affected if the pulmonary valve could not open?

- a. Blood could not reach the rest of the body.
- b. Blood could not reach the lungs.
- c. Blood could not return from the lungs.
- d. Blood could not return from the rest of the body.

32.

The diagram below shows the internal anatomy of the heart. How would blood circulation beyond the heart be affected if the tricuspid valve could not open?

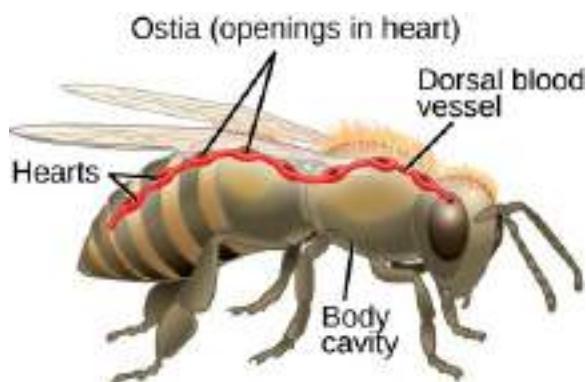

- a. Blood could not enter the pulmonary veins; therefore, it could not reach the lungs.
- b. Blood could not enter the pulmonary artery; therefore, it could not reach the heart.
- c. Blood could not enter the pulmonary artery; therefore, it could not reach the lungs.
- d. Blood could not enter the pulmonary veins; therefore, it could not reach the heart.
- 33.** Why is it useful for blood to travel slowly through capillary beds?
- a. To allow antibodies to enter infected cells and to promote the diffusion of fluid into the interstitial space.
- b. To assist with gas and nutrient exchange and to prevent the diffusion of fluid into the interstitial space.
- c. To assist with gas and nutrient exchange and to promote the diffusion of fluid into the interstitial space.
- d. To allow antibodies to enter infected cells and to prevent the diffusion of fluid into the interstitial space.

## TEST PREP FOR AP® COURSES

**34.** Insects have open circulatory systems in which blood, or hemolymph, circulates through the body cavity rather than through closed blood vessels. Birds, like other vertebrates, have closed circulatory systems in which blood remains within arteries, veins, and capillaries as it circulates. Based on their difference in circulatory system, which of the following statements best describes an organism that would be favored by selection during a food shortage?

- a. Insects would be favored because an open circulatory system requires less energy.
- b. Insects would be favored because an open circulatory system stores energy.
- c. Birds would be favored because a closed circulatory system loses less energy to heat.
- d. Birds would be favored because a closed circulatory system is more efficient at delivering nutrients.

**35.**

This diagram shows how insects have a heart that is elongated throughout much of their body. This is opposed to the heart of vertebrates, such as humans, which does not spread throughout the length of the body. Why was it likely advantageous for insects to evolve an elongated heart as opposed to the centrally located heart of vertebrates?

- a. Because an elongated heart allows blood to easily reach all the parts of the body from the heart.
- b. Because the elongated heart allows more blood to reach all the parts of the body, it allows for more nutrient exchange.
- c. Because an elongated heart allows blood to easily return to the heart from a few points within the body cavity.
- d. Because an elongated heart allows blood to easily return to the heart from most points within the body cavity.

**36.** Insects have open circulatory systems in which blood, or hemolymph, circulates through the body cavity rather than through closed blood vessels. Birds, like other vertebrates, have closed circulatory systems in which blood remains within arteries, veins, and capillaries as it circulates. How has this difference most likely influenced the evolution of birds and insects?

- a. The open circulatory system of birds warms their entire body quicker, allowing them to live in colder climates more successfully than insects.
- b. The closed circulatory system allows blood flow to increase to the flight muscles during flight, allowing insects to be better fliers than birds.
- c. The greater efficiency of a closed circulatory system allowed birds to become larger than insects.
- d. The simplicity of the open circulatory system allows insects to have a higher metabolism than birds.

**37.** Serum is used to diagnose and monitor diseases, and it is also used to classify blood types. Which of the following statements best describes serum?

- a. It is a liquid consisting of 90% water and has coagulation factors.
- b. It is plasma without the coagulation factors.
- c. Serum is only made of albumin.
- d. Serum is the same substance as interstitial fluid.

38. Explain how blood types are distinguished from one another.

- a. Blood types are distinguished on the basis of the presence or absence of different carbohydrates found on the surface of red blood cells.
- b. Blood types are distinguished on the basis of the presence or absence of different proteins found inside the red blood cells.
- c. Blood types are distinguished on the basis of the presence or absence of different lipids found on the surface of red blood cells.
- d. Blood types are distinguished based on the presence or absence of different antigens found on the surface of the red blood cells.

39. The inflammatory response involves increasing blood flow to areas of the body that contain immune system cells fighting a pathogen or foreign object. The inflammatory response is an example of a positive feedback loop. Based on this, what would cause the inflammatory response to stop in a certain area of the body?

- a. The white blood cells destroy all of the pathogens/foreign objects.
- b. The white blood cells disperse away from the site.
- c. More white blood cells arrive to fight the pathogens/foreign objects.
- d. Fewer white blood cells are needed to finish fighting the infection

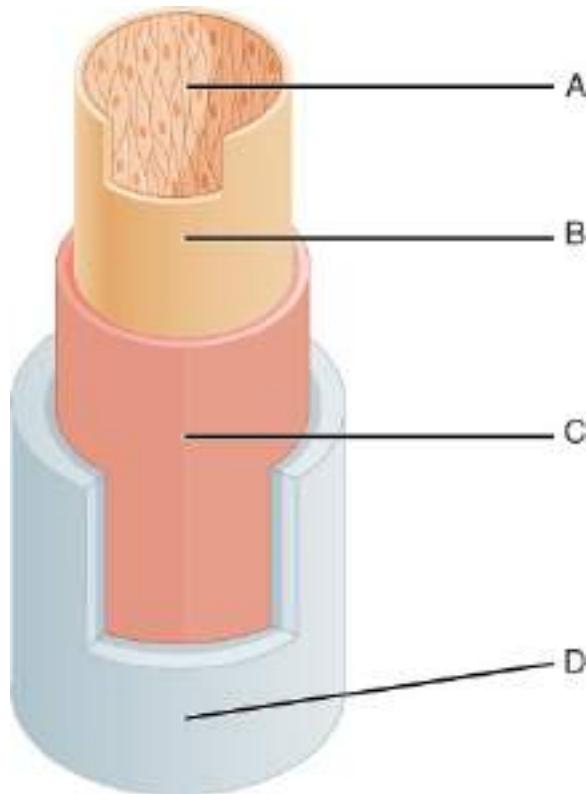

40. \_\_\_\_\_ is the phase of the cardiac cycle where the heart contracts, which pushes out the blood and pumps it around the body.

- a. diastole
- b. cardiac output
- c. myocardial infarction
- d. systole

41. In routine physicals, doctors often test for problems with the electrical activity of your heart. A(n) \_\_\_\_\_ can measure the electrical impulses in the heart.

- a. endocardium
- b. electrocardiogram (ECG)
- c. peripheral resistance
- d. cardiac output

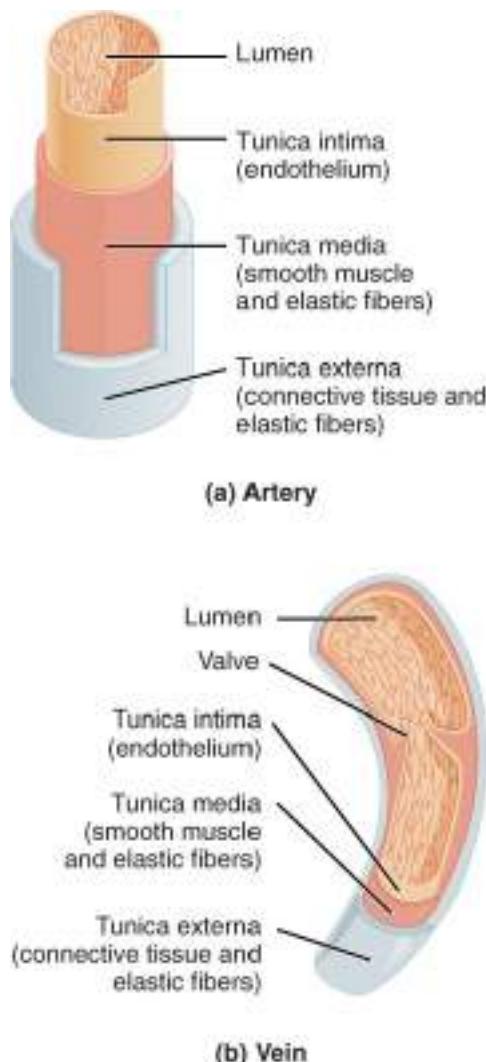

42.

The diagram shows a cross section of a blood vessel. Which part of the labeled structure would allow vasodilation in the blood vessel and under what conditions would vasodilation occur?

- a. Part B would allow vasodilation in the blood vessel if the blood vessel brings blood to relatively inactive cells, such as fat cells.
- b. Part C would allow vasodilation in the blood vessel if the heart and body's metabolism slow.
- c. Part B would allow vasodilation in the blood vessel if the blood vessel takes blood away from an active organ system.
- d. Part C would allow vasodilation in the blood vessel if the blood vessel takes blood to a muscle cell that is contracting quickly.

43.

The diagram shows a cross section of an artery and vein. What is the function of the tunica externa and why is it thicker in the artery than in the vein?

- The tunica externa prevents blood cell adhesion to the wall of the vessel. It is thicker in the artery to protect against the higher blood pressure found in arteries.
- The tunica externa protects the vessel from wear and tear and also provides support for the vessel. It is thicker in the artery to protect against the higher blood pressure found in arteries.
- The tunica externa protects the vessel from wear and tear and provides support for the vessel. It is thicker in the artery to protect against the lower blood pressure found in arteries.
- The tunica externa prevents blood cell adhesion to the wall of the vessel. It is thicker in the artery to protect against the lower blood pressure found in arteries.

## SCIENCE PRACTICE CHALLENGE QUESTIONS

**44.** Like Gram-positive bacteria, red blood cells have carbohydrates on the cell surface. The A, B, A/B, and O blood types are designations of the phenotypes expressed by the alleles that code for these cell surface carbohydrates.

A. **Describe** the relationship between regulation of expression and the differences among the A, B, A/B, and O types of blood cells.

B. **Explain** how the blood group phenotype does not display non-Mendelian inheritance and the simplest alternative model that explains this deviation.

Immune system T-cells recognize cell surface carbohydrates of bacterial and red blood cells. That these similarities have consequences for survival is indicated by the observation that individuals with blood type O are more susceptible to infection by *Vibrio*, the Gram-negative bacteria that causes cholera, and individuals with type A/B are more susceptible to infections from a broad range of *E. coli* variants, all of which are also Gram-negative.

C. **Describe** the likely reason for the increased susceptibility of individuals with type A/B blood in terms of the antigen-antibody model of specific immune response. **Justify** the selection of data that would allow a test of your reasoning.

D. The distribution of blood types was determined in a population. The results are displayed in the table.

| Type     | Observed | Frequency |
|----------|----------|-----------|
| A        | 501      |           |
| B        | 794      |           |
| A/B      | 236      |           |
| O        | 601      |           |
| Total, N | 2132     |           |

Table 31.1

Recall that the frequency of an allele can be determined if the genotype is known. For example, for a gene with two possible alleles the frequency of the dominant allele in a homozygous dominant population is just twice the number of individuals  $2N$  divided by the number of alleles which is  $2N$  also since each individual has 2 alleles at each gene. The frequency would be 1. For a population composed entirely of heterozygous individuals the frequency would be 0.5.

- Using the usual mathematical relationship and the three-allele system calculate the frequency of each type and add that value to the table.

From these frequencies the probabilities of the A, B, and O alleles in the population were determined as shown in the table below.

| Allele | probability |
|--------|-------------|
| A      | 0.201       |
| B      | 0.265       |
| O      | 0.542       |

Table 31.2

- Using these probabilities **calculate** the expected frequencies, E, of each blood type using

$$E(A) = (p_A^2 + 2p_A p_O)N$$

$$E(B) = (p_B^2 + 2p_B p_O)N$$

$$E(A/B) = 2 \cdot p_A \cdot p_B \cdot N$$

$$E(O) = p_O^2 \cdot N$$

Add these expected frequencies to the table.

| Type | Observed,<br>O | Expected Frequency,<br>E |
|------|----------------|--------------------------|
| A    | 501            |                          |
| B    | 794            |                          |
| A/B  | 236            |                          |
| O    | 601            |                          |

Table 31.3

- Apply your understanding** of the conceptual foundation of these equations by restating in words the relationship represented by  $E(A)$ .

- Apply a  $\chi^2$  test at the 95% confidence level and 3 degrees of freedom (number of traits minus one) to **evaluate the claim** that these data indicate Hardy-Weinberg equilibrium of the ABO system for this population. The definition of the statistic

$$\chi^2 = \sum \frac{(O - E)^2}{E}$$

and this table are provided on the AP Biology Exam.

| Degrees of Freedom |      |      |       |       |       |       |       |       |
|--------------------|------|------|-------|-------|-------|-------|-------|-------|
| p                  | 1    | 2    | 3     | 4     | 5     | 6     | 7     | 8     |
| 0.05               | 3.84 | 5.99 | 7.82  | 9.49  | 11.07 | 12.59 | 14.07 | 15.51 |
| 0.01               | 6.64 | 9.32 | 11.34 | 13.28 | 15.09 | 16.81 | 18.48 | 20.09 |

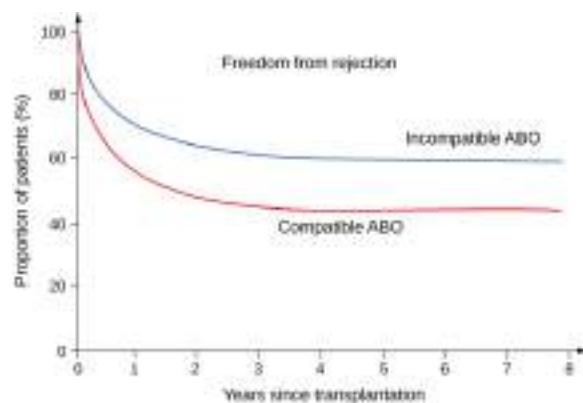

Table 31.4

- Hardy-Weinberg equilibrium is consistent with the assumption of no change in the distribution of alleles over time. **Justify the selection of data** that should be obtained to further test this assumption.

Homologous genes coding for the carbohydrates that are presented on the surfaces of red blood cells are found in amphibians and mammals but not in fish, implying a last common ancestor for the ABO gene system at least 20 million years ago.

E. The difference between genes coding for A and B is a single nucleotide replacement. **Evaluate** the likelihood that negative selection pressures have been active in the evolution of this system.

45. The immune system rejection of transplanted organs and the availability of organ donors are key factors in determining survival. Blood ABO compatibility is always a criterion in matching donors and recipients in adult patients and was once a consideration for infant patients. Period of time on the waitlist for a suitable donor is critical because the health of the patient degrades while waiting. Dipchand *et al.* (*American Journal of Transplantation*, 10, 2010) made a comparison of survival rates for infants where the donor heart was ABO compatible and incompatible as shown in the graph.

**Figure 31.21**

Based on these data justify the claim that expression of blood group immune response develops over time and that this provides a window of opportunity for transplantation.

# 32 | OSMOTIC REGULATION AND EXCRETION

**Figure 32.1** Just as humans recycle what we can and dump the remains into landfills, our bodies use and recycle what they can and excrete the remaining waste products. Our bodies' complex systems have developed ways to treat waste and maintain a balanced internal environment. (credit: modification of work by Redwin Law)

## Chapter Outline

- 32.1: Osmoregulation and Osmotic Balance**
- 32.2: The Kidneys and Osmoregulatory Organs**
- 32.3: Excretion Systems**
- 32.4: Nitrogenous Wastes**
- 32.5: Hormonal Control of Osmoregulatory Functions**

## Introduction

The daily intake recommendation for human water consumption is eight to ten glasses of water. In order to achieve a healthy balance, the human body should excrete the eight to ten glasses of water every day. This occurs via the processes of urination, defecation, sweating and, to a small extent, respiration. The organs and tissues of the human body are soaked in fluids that are maintained at constant temperature, pH, and solute concentration, all crucial elements of homeostasis. The solutes in body fluids are mainly mineral salts and sugars, and osmotic regulation is the process by which the mineral salts and water are kept in balance. Osmotic homeostasis is maintained despite the influence of external factors like temperature, diet, and weather conditions.

Osmotic balance is especially important in the brain. The brain is 80% water, and osmotic balance between water and spinal fluid is critical to proper brain function. Too much or too little water can cause severe medical conditions. Researchers have recently discovered the mechanism that controls water flow between brain cells. The speed of water flow is controlled by water channels called aquaporin channels, which are controlled by a neurotransmitter called gamma-aminobutyric acid. You can read more about this interesting research at the [Science Daily website \(<http://openstaxcollege.org/l/32brain>\)](http://openstaxcollege.org/l/32brain).

## 32.1 | Osmoregulation and Osmotic Balance

In this section, you will explore the following questions:

- Why are osmoregulation and osmotic balance important to body functions?
- What is osmolarity and how is it measured?
- What are osmoregulators or osmoconformers, and how do these tools allow animals to adapt to different environments?

### Connection for AP® Courses

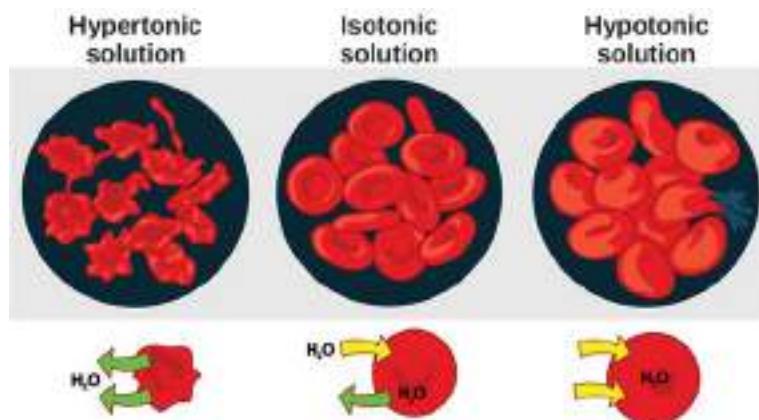

Much of the information in this chapter is not within the scope for AP®. However, the chapter is filled with illustrative examples that are applicable to concepts we've explored previously, including chemistry, structure of the plasma cell membrane, and movement of molecules across membranes. With this in mind, it is helpful to have a general understanding how the human body, specifically the excretory system, maintains osmotic homeostasis despite the influence of external factors like temperature, diet, and varying environmental conditions. For example, if we drink eight to ten glasses of water per day, the human body excretes that water via urination, defecation, sweating, and, to a small extent, respiration.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>2.12</b> The student is able to use representations and models to analyze situations or solve problems qualitatively and quantitatively to investigate whether dynamic homeostasis is maintained by the active movement of molecules across membranes. |

Osmosis is the diffusion of water across a membrane in response to **osmotic pressure** caused by an imbalance of molecules on either side of the membrane. **Osmoregulation** is the process of maintenance of salt and water balance (**osmotic balance**) across membranes within the body's fluids, which are composed of water, plus electrolytes and non-electrolytes. An

**electrolyte** is a solute that dissociates into ions when dissolved in water. A **non-electrolyte**, in contrast, doesn't dissociate into ions during water dissolution. Both electrolytes and non-electrolytes contribute to the osmotic balance. The body's fluids include blood plasma, the cytosol within cells, and interstitial fluid, the fluid that exists in the spaces between cells and tissues of the body. The membranes of the body (such as the pleural, serous, and cell membranes) are **semi-permeable membranes**. Semi-permeable membranes are permeable (or permissive) to certain types of solutes and water. Solutions on two sides of a semi-permeable membrane tend to equalize in solute concentration by movement of solutes and/or water across the membrane. As seen in **Figure 32.2**, a cell placed in water tends to swell due to gain of water from the hypotonic or "low salt" environment. A cell placed in a solution with higher salt concentration, on the other hand, tends to make the membrane shrivel up due to loss of water into the hypertonic or "high salt" environment. Isotonic cells have an equal concentration of solutes inside and outside the cell; this equalizes the osmotic pressure on either side of the cell membrane which is a semi-permeable membrane.

**Figure 32.2** Cells placed in a hypertonic environment tend to shrink due to loss of water. In a hypotonic environment, cells tend to swell due to intake of water. The blood maintains an isotonic environment so that cells neither shrink nor swell. (credit: Mariana Ruiz Villareal)

The body does not exist in isolation. There is a constant input of water and electrolytes into the system. While osmoregulation is achieved across membranes within the body, excess electrolytes and wastes are transported to the kidneys and excreted, helping to maintain osmotic balance.

## Need for Osmoregulation

Biological systems constantly interact and exchange water and nutrients with the environment by way of consumption of food and water and through excretion in the form of sweat, urine, and feces. Without a mechanism to regulate osmotic pressure, or when a disease damages this mechanism, there is a tendency to accumulate toxic waste and water, which can have dire consequences.

Mammalian systems have evolved to regulate not only the overall osmotic pressure across membranes, but also specific concentrations of important electrolytes in the three major fluid compartments: blood plasma, extracellular fluid, and intracellular fluid. Since osmotic pressure is regulated by the movement of water across membranes, the volume of the fluid compartments can also change temporarily. Because blood plasma is one of the fluid components, osmotic pressures have a direct bearing on blood pressure.

## Transport of Electrolytes across Cell Membranes

Electrolytes, such as sodium chloride, ionize in water, meaning that they dissociate into their component ions. In water, sodium chloride ( $NaCl$ ), dissociates into the sodium ion ( $Na^+$ ) and the chloride ion ( $Cl^-$ ). The most important ions, whose concentrations are very closely regulated in body fluids, are the cations sodium ( $Na^+$ ), potassium ( $K^+$ ), calcium ( $Ca^{+2}$ ), magnesium ( $Mg^{+2}$ ), and the anions chloride ( $Cl^-$ ), carbonate ( $CO_3^{-2}$ ), bicarbonate ( $HCO_3^-$ ), and phosphate ( $PO_3^-$ ). Electrolytes are lost from the body during urination and perspiration. For this reason, athletes are encouraged to replace electrolytes and fluids during periods of increased activity and perspiration.

Osmotic pressure is influenced by the concentration of solutes in a solution. It is directly proportional to the number of solute atoms or molecules and not dependent on the size of the solute molecules. Because electrolytes dissociate into their component ions, they, in essence, add more solute particles into the solution and have a greater effect on osmotic pressure, per mass than compounds that do not dissociate in water, such as glucose.

Water can pass through membranes by passive diffusion. If electrolyte ions could passively diffuse across membranes, it

would be impossible to maintain specific concentrations of ions in each fluid compartment therefore they require special mechanisms to cross the semi-permeable membranes in the body. This movement can be accomplished by facilitated diffusion and active transport. Facilitated diffusion requires protein-based channels for moving the solute. Active transport requires energy in the form of ATP conversion, carrier proteins, or pumps in order to move ions against the concentration gradient.

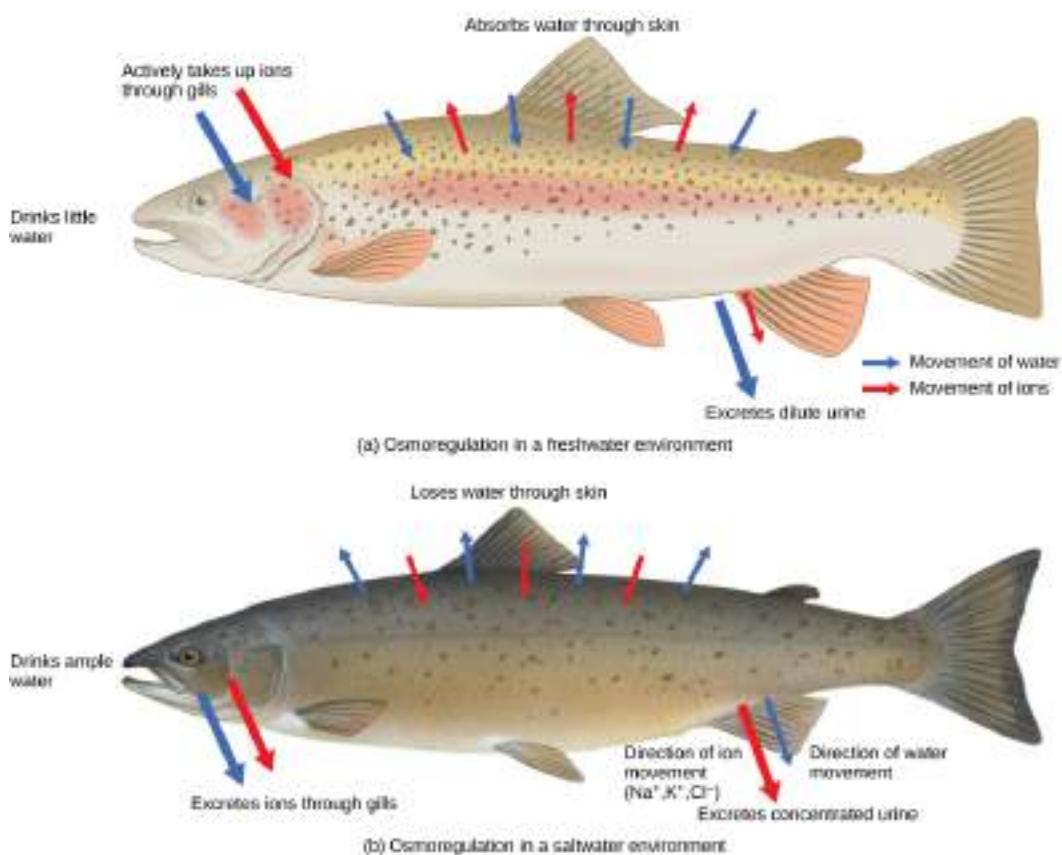

## Concept of Osmolality and Milliequivalent

In order to calculate osmotic pressure, it is necessary to understand how solute concentrations are measured. The unit for measuring solutes is the **mole**. One mole is defined as the gram molecular weight of the solute. For example, the molecular weight of sodium chloride is 58.44. Thus, one mole of sodium chloride weighs 58.44 grams. The **molarity** of a solution is the number of moles of solute per liter of solution. The **molality** of a solution is the number of moles of solute per kilogram of solvent. If the solvent is water, one kilogram of water is equal to one liter of water. While molarity and molality are used to express the concentration of solutions, electrolyte concentrations are usually expressed in terms of milliequivalents per liter (mEq/L): the mEq/L is equal to the ion concentration (in millimoles) multiplied by the number of electrical charges on the ion. The unit of milliequivalent takes into consideration the ions present in the solution (since electrolytes form ions in aqueous solutions) and the charge on the ions.

Thus, for ions that have a charge of one, one milliequivalent is equal to one millimole. For ions that have a charge of two (like calcium), one milliequivalent is equal to 0.5 millimoles. Another unit for the expression of electrolyte concentration is the milliosmole (mOsm), which is the number of milliequivalents of solute per kilogram of solvent. Body fluids are usually maintained within the range of 280 to 300 mOsm.

## Osmoregulators and Osmoconformers

Persons lost at sea without any fresh water to drink are at risk of severe dehydration because the human body cannot adapt to drinking seawater, which is hypertonic in comparison to body fluids. Organisms such as goldfish that can tolerate only a relatively narrow range of salinity are referred to as stenohaline. About 90 percent of all bony fish are restricted to either freshwater or seawater. They are incapable of osmotic regulation in the opposite environment. It is possible, however, for a few fishes like salmon to spend part of their life in fresh water and part in sea water. Organisms like the salmon and molly that can tolerate a relatively wide range of salinity are referred to as euryhaline organisms. This is possible because some fish have evolved **osmoregulatory** mechanisms to survive in all kinds of aquatic environments. When they live in fresh water, their bodies tend to take up water because the environment is relatively hypotonic, as illustrated in **Figure 32.3a**. In such hypotonic environments, these fish do not drink much water. Instead, they pass a lot of very dilute urine, and they achieve electrolyte balance by active transport of salts through the gills. When they move to a hypertonic marine environment, these fish start drinking sea water; they excrete the excess salts through their gills and their urine, as illustrated in **Figure 32.3b**. Most marine invertebrates, on the other hand, may be isotonic with sea water (**osmoconformers**). Their body fluid concentrations conform to changes in seawater concentration. Cartilaginous fishes' salt composition of the blood is similar to bony fishes; however, the blood of sharks contains the organic compounds urea and trimethylamine oxide (TMAO). This does not mean that their electrolyte composition is similar to that of sea water. They achieve isotonicity with the sea by storing large concentrations of urea. These animals that secrete urea are called ureotelic animals. TMAO stabilizes proteins in the presence of high urea levels, preventing the disruption of peptide bonds that would occur in other animals exposed to similar levels of urea. Sharks are cartilaginous fish with a rectal gland to secrete salt and assist in osmoregulation.

**Figure 32.3** Fish are osmoregulators, but must use different mechanisms to survive in (a) freshwater or (b) saltwater environments. (credit: modification of work by Duane Raver, NOAA)

## career CONNECTION

### Dialysis Technician

Dialysis is a medical process of removing wastes and excess water from the blood by diffusion and ultrafiltration. When kidney function fails, dialysis must be done to artificially rid the body of wastes. This is a vital process to keep patients alive. In some cases, the patients undergo artificial dialysis until they are eligible for a kidney transplant. In others who are not candidates for kidney transplants, dialysis is a life-long necessity.

Dialysis technicians typically work in hospitals and clinics. While some roles in this field include equipment development and maintenance, most dialysis technicians work in direct patient care. Their on-the-job duties, which typically occur under the direct supervision of a registered nurse, focus on providing dialysis treatments. This can include reviewing patient history and current condition, assessing and responding to patient needs before and during treatment, and monitoring the dialysis process. Treatment may include taking and reporting a patient's vital signs and preparing solutions and equipment to ensure accurate and sterile procedures.

## everyday CONNECTION for AP<sup>®</sup> Courses

Patients undergoing dialysis use dialysis machines such as the one shown here. Their blood runs through a tube that is immersed in a solution, with the walls of the tube actually being semipermeable membranes. The solution is made so that urea, the main waste product produced by humans, is pulled out of the blood through diffusion. The semi-permeable tube wall allows urea through, but keeps the larger components of the blood, such as proteins and blood cells, within the tube. The “cleaned” blood is eventually returned to the body.

**Figure 32.4**

How do dialysis machines remove harmful urea from the blood?

- a. by facilitated diffusion that allows urea to diffuse out of the blood
- b. by active transport, which allows urea to diffuse out of the blood
- c. by creating an osmotic gradient that allows urea to diffuse out of the blood across a permeable membrane
- d. by creating an osmotic gradient that allows urea to diffuse out of the blood

## science practices CONNECTION for AP<sup>®</sup> Courses

### Think About It

Why is excretion important in order to achieve osmotic balance?

## 32.2 | The Kidneys and Osmoregulatory Organs

In this section, you will explore the following questions:

- How does the structure of the kidneys relate to its function as the main osmoregulatory organs in mammalian systems?
- How is the nephron the functional unit of the kidney and how does it actively filter blood and generate urine?
- What are the roles of glomerular filtration, tubular reabsorption, and tubular secretion in the formation of urine?

## Connection for AP® Courses

Much of the information in this section is outside the scope for AP®. Although the curriculum does not require you to have detailed knowledge about the structure and physiology of the kidneys, learning how we filter blood to eliminate wastes—while also retaining vital water and other substances—provides an opportunity to apply concepts we’ve explored previously. Lack of kidney function can have detrimental effects on our health.

In coordination with the circulatory and endocrine systems, the human excretory system serves several functions: excretion of metabolic wastes, maintenance of water-salt balance (osmoregulation), maintenance of pH balance, and production of hormones. The organs of the system are the kidneys, ureters, urinary bladder, and urethra. Specialized cells of the kidney called nephrons (not to be confused with neurons of the nervous system) are closely associated with capillaries. Urine formation by nephrons involves three steps: filtration, in which water, nutrients, and wastes pass from the blood into the nephron; reabsorption, in which nutrients such as glucose and most water are reabsorbed back into the blood; and secretion, in which additional wastes and  $H^+$  are added to urine to maintain homeostatic pH. The processes of diffusion, osmosis, and active transport ensure that the urine excreted from the body is hypertonic, thus preventing dehydration. For example, water is reabsorbed throughout nephron tubules back into capillaries via osmosis, and in another part of the tubule (ascending loop of Henle),  $Na^+$  and  $Cl^-$  are actively transported into the interstitial fluid.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 4 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

| <b>Learning Objective</b>         | <b>4.18</b> The student is able to use representations and models to analyze how cooperation interactions within organisms promote efficiency in the use of energy and matter. |

Although the kidneys are the major osmoregulatory organ, the skin and lungs also play a role in the process. Water and electrolytes are lost through sweat glands in the skin, which helps moisturize and cool the skin surface, while the lungs

expel a small amount of water in the form of mucous secretions and via evaporation of water vapor.

## Kidneys: The Main Osmoregulatory Organ

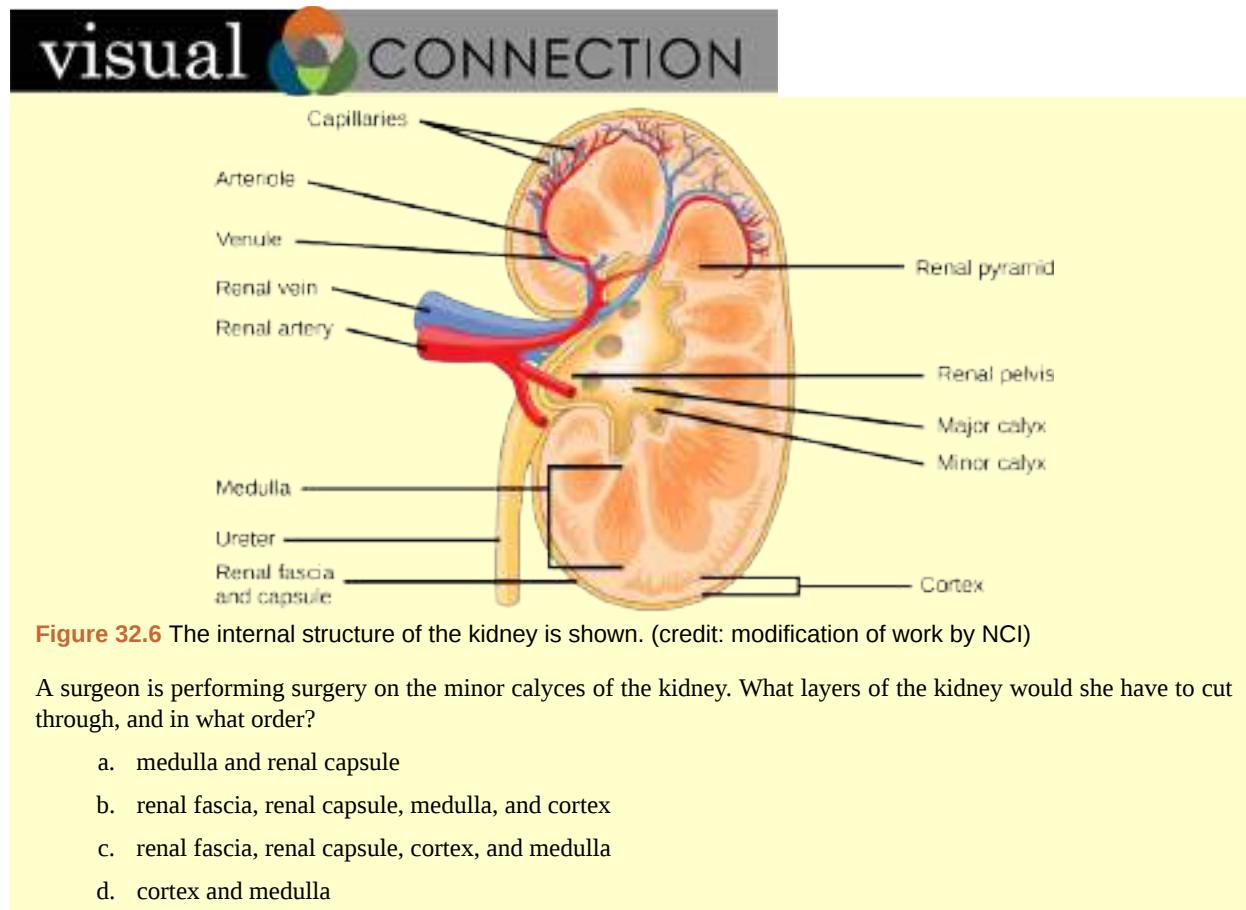

The **kidneys**, illustrated in **Figure 32.5**, are a pair of bean-shaped structures that are located just below and posterior to the liver in the peritoneal cavity. The adrenal glands sit on top of each kidney and are also called the suprarenal glands. Kidneys filter blood and purify it. All the blood in the human body is filtered many times a day by the kidneys; these organs use up almost 25 percent of the oxygen absorbed through the lungs to perform this function. Oxygen allows the kidney cells to efficiently manufacture chemical energy in the form of ATP through aerobic respiration. The filtrate coming out of the kidneys is called **urine**.

**Figure 32.5** Kidneys filter the blood, producing urine that is stored in the bladder prior to elimination through the urethra. (credit: modification of work by NCI)

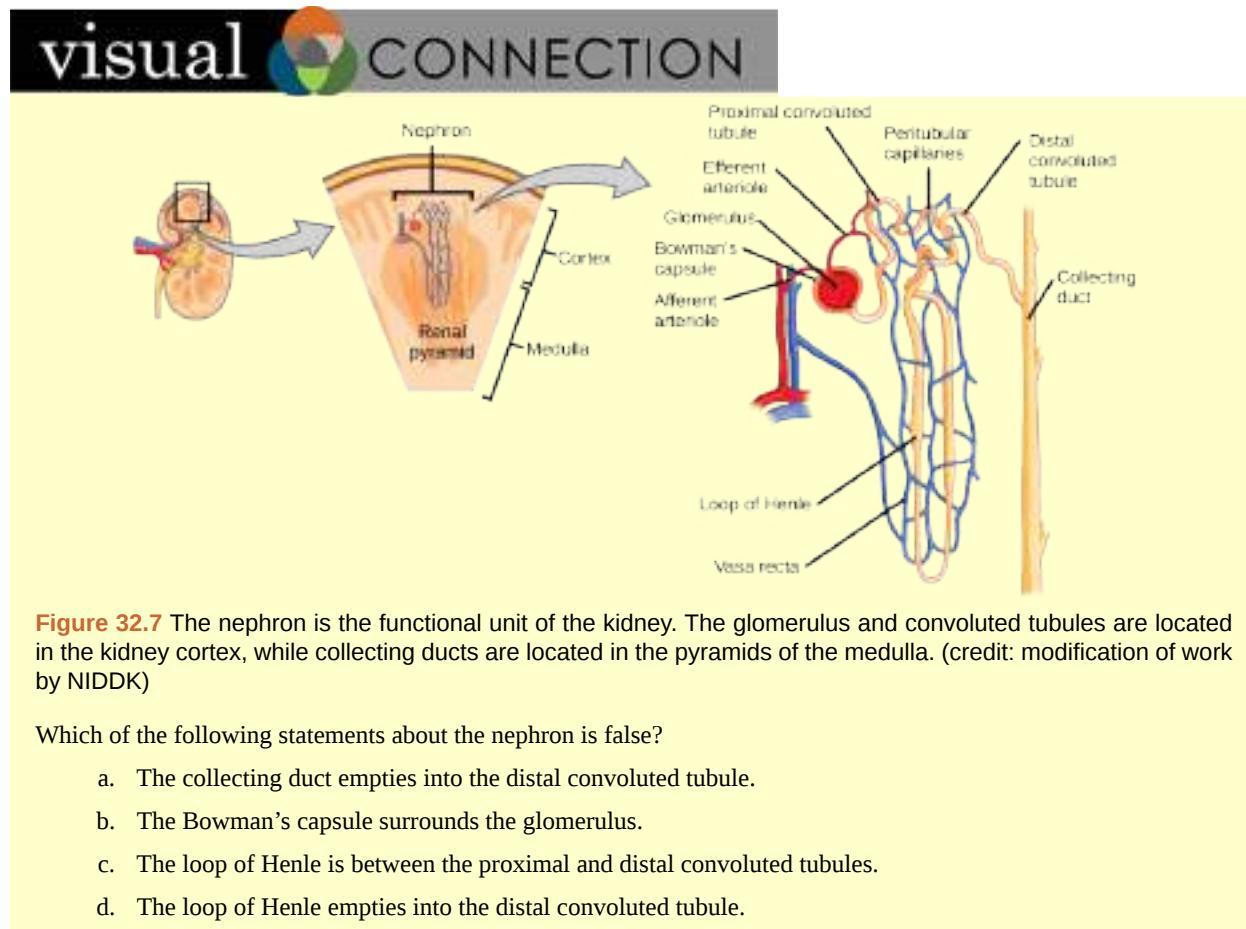

## Kidney Structure

Externally, the kidneys are surrounded by three layers, illustrated in **Figure 32.6**. The outermost layer is a tough connective tissue layer called the **renal fascia**. The second layer is called the **perirenal fat capsule**, which helps anchor the kidneys in place. The third and innermost layer is the **renal capsule**. Internally, the kidney has three regions—an outer **cortex**, a **medulla** in the middle, and the **renal pelvis** in the region called the **hilum** of the kidney. The hilum is the concave part of the bean-shape where blood vessels and nerves enter and exit the kidney; it is also the point of exit for the ureters. The renal cortex is granular due to the presence of **nephrons**—the functional unit of the kidney. The medulla consists of multiple pyramidal tissue masses, called the **renal pyramids**. In between the pyramids are spaces called **renal columns** through which the blood vessels pass. The tips of the pyramids, called renal papillae, point toward the renal pelvis. There are, on average, eight renal pyramids in each kidney. The renal pyramids along with the adjoining cortical region are called the **lobes of the kidney**. The renal pelvis leads to the **ureter** on the outside of the kidney. On the inside of the kidney, the renal pelvis branches out into two or three extensions called the major **calyces**, which further branch into the minor calyces. The ureters are urine-bearing tubes that exit the kidney and empty into the **urinary bladder**.

Because the kidney filters blood, its network of blood vessels is an important component of its structure and function. The arteries, veins, and nerves that supply the kidney enter and exit at the renal hilum. Renal blood supply starts with the branching of the aorta into the **renal arteries** (which are each named based on the region of the kidney they pass through) and ends with the exiting of the **renal veins** to join the **inferior vena cava**. The renal arteries split into several **segmental arteries** upon entering the kidneys. Each segmental artery splits further into several **interlobar arteries** and enters the renal columns, which supply the renal lobes. The interlobar arteries split at the junction of the renal cortex and medulla to form the **arcuate arteries**. The arcuate “bow shaped” arteries form arcs along the base of the medullary pyramids. **Cortical radiate arteries**, as the name suggests, radiate out from the arcuate arteries. The cortical radiate arteries branch into numerous afferent arterioles, and then enter the capillaries supplying the nephrons. Veins trace the path of the arteries and have similar names, except there are no segmental veins.

As mentioned previously, the functional unit of the kidney is the nephron, illustrated in **Figure 32.7**. Each kidney is made up of over one million nephrons that dot the renal cortex, giving it a granular appearance when sectioned sagittally. There are two types of nephrons—**cortical nephrons** (85 percent), which are deep in the renal cortex, and **juxtamedullary nephrons** (15 percent), which lie in the renal cortex close to the renal medulla. A nephron consists of three parts—a **renal corpuscle**, a **renal tubule**, and the associated capillary network, which originates from the cortical radiate arteries.

**Figure 32.7** The nephron is the functional unit of the kidney. The glomerulus and convoluted tubules are located in the kidney cortex, while collecting ducts are located in the pyramids of the medulla. (credit: modification of work by NIDDK)

Which of the following statements about the nephron is false?

- The collecting duct empties into the distal convoluted tubule.
- The Bowman's capsule surrounds the glomerulus.
- The loop of Henle is between the proximal and distal convoluted tubules.
- The loop of Henle empties into the distal convoluted tubule.

### **Renal Corpuscle**

The renal corpuscle, located in the renal cortex, is made up of a network of capillaries known as the **glomerulus** and the capsule, a cup-shaped chamber that surrounds it, called the glomerular or **Bowman's capsule**.

### **Renal Tubule**

The renal tubule is a long and convoluted structure that emerges from the glomerulus and can be divided into three parts based on function. The first part is called the **proximal convoluted tubule (PCT)** due to its proximity to the glomerulus; it stays in the renal cortex. The second part is called the **loop of Henle**, or nephritic loop, because it forms a loop (with **descending** and **ascending limbs**) that goes through the renal medulla. The third part of the renal tubule is called the **distal convoluted tubule (DCT)** and this part is also restricted to the renal cortex. The DCT, which is the last part of the nephron, connects and empties its contents into collecting ducts that line the medullary pyramids. The collecting ducts amass contents from multiple nephrons and fuse together as they enter the papillae of the renal medulla.

### **Capillary Network within the Nephron**

The capillary network that originates from the renal arteries supplies the nephron with blood that needs to be filtered. The branch that enters the glomerulus is called the **afferent arteriole**. The branch that exits the glomerulus is called the **efferent arteriole**. Within the glomerulus, the network of capillaries is called the glomerular capillary bed. Once the efferent arteriole exits the glomerulus, it forms the **peritubular capillary network**, which surrounds and interacts with parts of the renal tubule. In cortical nephrons, the peritubular capillary network surrounds the PCT and DCT. In juxamedullary nephrons, the peritubular capillary network forms a network around the loop of Henle and is called the **vasa recta**.

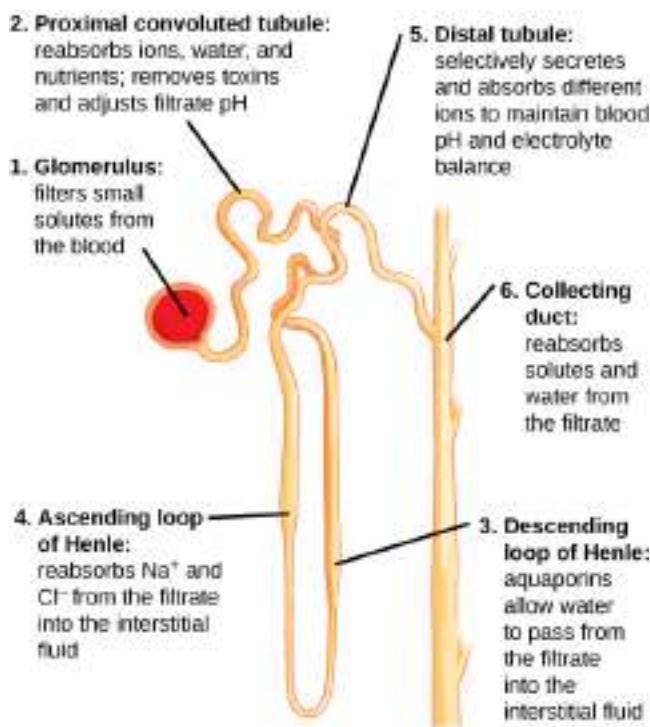

Go to [this website](http://openstaxcollege.org/l/kidney_section) ([http://openstaxcollege.org/l/kidney\\_section](http://openstaxcollege.org/l/kidney_section)) to see another coronal section of the kidney and to explore an animation of the workings of nephrons.

Describe the structure of the kidneys.

- a. Externally, the kidneys are surrounded by three layers. The outermost layer is the renal fascia, the second layer is the perineal fat capsule, and the third layer is the renal capsule. Internally, the kidney has three layers: an outer cortex, the middle medulla, and the inner renal pelvis.
- b. Externally, the kidneys are surrounded by three layers. The outermost layer is the renal fascia, the second layer is the perineal fat capsule, and the third layer is the renal capsule. Internally, the kidney has three layers: an outer medulla, the middle cortex, and the inner renal pelvis.
- c. Externally, the kidneys are surrounded by three layers. The outermost layer is the renal capsule, the second layer is the perineal fat capsule, and the third layer is the renal fascia. Internally, the kidney has three layers: an outer cortex, the middle medulla, and the inner renal pelvis.
- d. Externally, the kidneys are surrounded by three layers. The outermost layer is the renal fascia, the second layer is the perineal fat capsule, and the third layer is the renal capsule. Internally, the kidney has three layers: an outer cortex, the middle hilum, and the inner renal pelvis.

## Kidney Function and Physiology

Kidneys filter blood in a three-step process. First, the nephrons filter blood that runs through the capillary network in the glomerulus. Almost all solutes, except for proteins, are filtered out into the glomerulus by a process called **glomerular filtration**. Second, the filtrate is collected in the renal tubules. Most of the solutes get reabsorbed in the PCT by a process called **tubular reabsorption**. In the loop of Henle, the filtrate continues to exchange solutes and water with the renal medulla and the peritubular capillary network. Water is also reabsorbed during this step. Then, additional solutes and wastes are secreted into the kidney tubules during **tubular secretion**, which is, in essence, the opposite process to tubular reabsorption. The collecting ducts collect filtrate coming from the nephrons and fuse in the medullary papillae. From here, the papillae deliver the filtrate, now called urine, into the minor calyces that eventually connect to the ureters through the renal pelvis. This entire process is illustrated in [Figure 32.8](#).

**Figure 32.8** Each part of the nephron performs a different function in filtering waste and maintaining homeostatic balance. (1) The glomerulus forces small solutes out of the blood by pressure. (2) The proximal convoluted tubule reabsorbs ions, water, and nutrients from the filtrate into the interstitial fluid, and actively transports toxins and drugs from the interstitial fluid into the filtrate. The proximal convoluted tubule also adjusts blood pH by selectively secreting ammonia ( $\text{NH}_3$ ) into the filtrate, where it reacts with  $\text{H}^+$  to form  $\text{NH}_4^+$ . The more acidic the filtrate, the more ammonia is secreted. (3) The descending loop of Henle is lined with cells containing aquaporins that allow water to pass from the filtrate into the interstitial fluid. (4) In the thin part of the ascending loop of Henle,  $\text{Na}^+$  and  $\text{Cl}^-$  ions diffuse into the interstitial fluid. In the thick part, these same ions are actively transported into the interstitial fluid. Because salt but not water is lost, the filtrate becomes more dilute as it travels up the limb. (5) In the distal convoluted tubule,  $\text{K}^+$  and  $\text{H}^+$  ions are selectively secreted into the filtrate, while  $\text{Na}^+$ ,  $\text{Cl}^-$ , and  $\text{HCO}_3^-$  ions are reabsorbed to maintain pH and electrolyte balance in the blood. (6) The collecting duct reabsorbs solutes and water from the filtrate, forming dilute urine. (credit: modification of work by NIDDK)

### Glomerular Filtration

Glomerular filtration filters out most of the solutes due to high blood pressure and specialized membranes in the afferent arteriole. The blood pressure in the glomerulus is maintained independent of factors that affect systemic blood pressure. The “leaky” connections between the endothelial cells of the glomerular capillary network allow solutes to pass through easily. All solutes in the glomerular capillaries, except for macromolecules like proteins, pass through by passive diffusion. There is no energy requirement at this stage of the filtration process. **Glomerular filtration rate (GFR)** is the volume of glomerular filtrate formed per minute by the kidneys. GFR is regulated by multiple mechanisms and is an important indicator of kidney function.

To learn more about the vascular system of kidneys, click through [this review](http://openstaxcollege.org/l/kidneys) (<http://openstaxcollege.org/l/kidneys>) and the steps of blood flow.

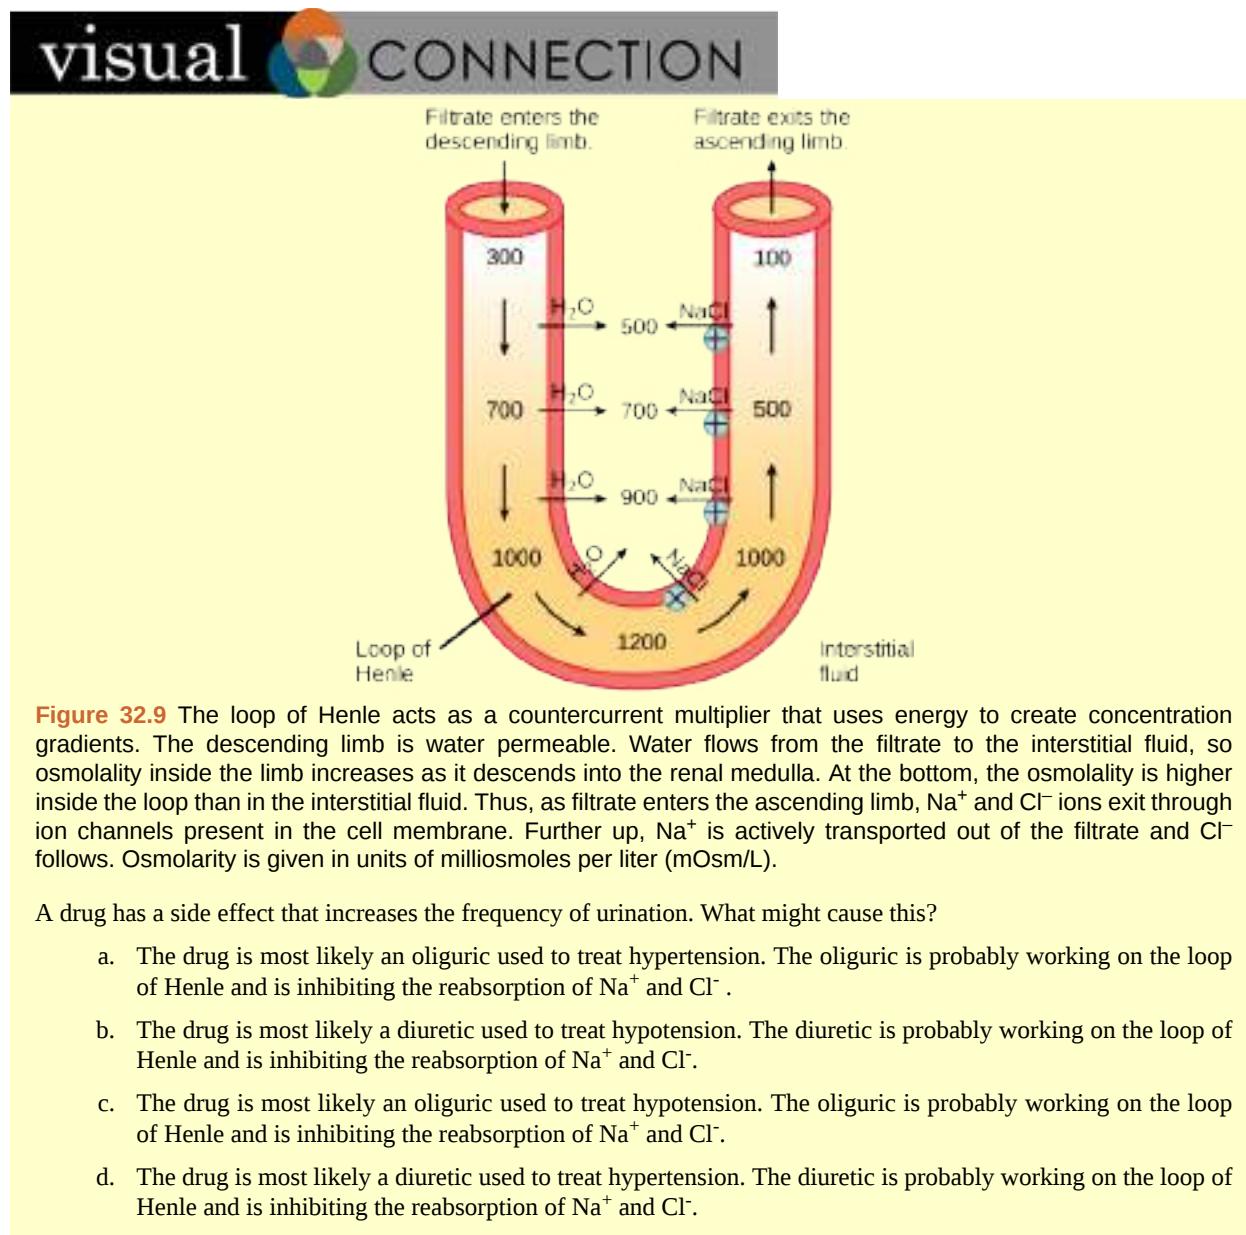

Explain the three-step process by which the kidneys filter blood.

- a. First, the nephrons filter blood that runs through the capillary network in the glomerulus, which filters out almost all solutes, except for proteins, by glomerular filtration. Second, the filtrate is collected in the renal tubules. Most of the solutes get reabsorbed in the proximal convoluted tubule by tubular secretion. Third, additional solutes and wastes are secreted into the tubules of the kidney during tubular reabsorption.
- b. First, the nephrons filter blood that runs through the capillary network in the glomerulus, which filters out almost all solutes, except for proteins, by glomerular filtration. Second, the filtrate is collected in the renal tubules. Most of the solutes get reabsorbed in the proximal convoluted tubule by tubular reabsorption. Third, additional solutes and wastes are secreted into the tubules of the kidney during tubular secretion.
- c. First, the nephrons filter blood that runs through the capillary network in the glomerulus, which filters out almost all solutes, except for uric acid, by glomerular filtration. Second, the filtrate is collected in the renal tubules. Most of the solutes get reabsorbed in the proximal convoluted tubule by tubular reabsorption. Third, additional solutes and wastes are secreted into the tubules of the kidney during tubular secretion.
- d. First, the nephrons filter blood that runs through the capillary network in the glomerulus, which filters out almost all solutes, except for proteins, by glomerular filtration. Second, the filtrate is collected in the renal tubules. Most of the solutes get reabsorbed in the distal convoluted tubule by tubular reabsorption. Third, additional solutes and wastes are secreted into the tubules of the kidney during tubular secretion.

### Tubular Reabsorption and Secretion

Tubular reabsorption occurs in the PCT part of the renal tubule. Almost all nutrients are reabsorbed, and this occurs either by passive or active transport. Reabsorption of water and some key electrolytes are regulated and can be influenced by hormones. Sodium ( $\text{Na}^+$ ) is the most abundant ion and most of it is reabsorbed by active transport and then transported to the peritubular capillaries. Because  $\text{Na}^+$  is actively transported out of the tubule, water follows it to even out the osmotic pressure. Water is also independently reabsorbed into the peritubular capillaries due to the presence of aquaporins, or water channels, in the PCT. This occurs due to the low blood pressure and high osmotic pressure in the peritubular capillaries. However, every solute has a **transport maximum** and the excess is not reabsorbed.

In the loop of Henle, the permeability of the membrane changes. The descending limb is permeable to water, not solutes; the opposite is true for the ascending limb. Additionally, the loop of Henle invades the renal medulla, which is naturally high in salt concentration and tends to absorb water from the renal tubule and concentrate the filtrate. The osmotic gradient increases as it moves deeper into the medulla. Because two sides of the loop of Henle perform opposing functions, as illustrated in [Figure 32.9](#), it acts as a **countercurrent multiplier**. The vasa recta around it acts as the **countercurrent exchanger**.

By the time the filtrate reaches the DCT, most of the urine and solutes have been reabsorbed. If the body requires additional water, all of it can be reabsorbed at this point. Further reabsorption is controlled by hormones, which will be discussed in a later section. Excretion of wastes occurs due to lack of reabsorption combined with tubular secretion. Undesirable products like metabolic wastes, urea, uric acid, and certain drugs, are excreted by tubular secretion. Most of the tubular secretion happens in the DCT, but some occurs in the early part of the collecting duct. Kidneys also maintain an acid-base balance by secreting excess H<sup>+</sup> ions.

Although parts of the renal tubules are named proximal and distal, in a cross-section of the kidney, the tubules are placed close together and in contact with each other and the glomerulus. This allows for exchange of chemical messengers between the different cell types. For example, the DCT ascending limb of the loop of Henle has masses of cells called **macula densa**, which are in contact with cells of the afferent arterioles called **juxtaglomerular cells**. Together, the macula densa and juxtaglomerular cells form the juxtaglomerular complex (JGC). The JGC is an endocrine structure that secretes the enzyme renin and the hormone erythropoietin. When hormones trigger the macula densa cells in the DCT due to variations in blood volume, blood pressure, or electrolyte balance, these cells can immediately communicate the problem to the capillaries in the afferent and efferent arterioles, which can constrict or relax to change the glomerular filtration rate of the kidneys.

## career CONNECTION

### Nephrologist

A nephrologist studies and deals with diseases of the kidneys—both those that cause kidney failure (such as diabetes) and the conditions that are produced by kidney disease (such as hypertension). Blood pressure, blood volume, and changes in electrolyte balance come under the purview of a nephrologist.

Nephrologists usually work with other physicians who refer patients to them or consult with them about specific diagnoses and treatment plans. Patients are usually referred to a nephrologist for symptoms such as blood or protein in the urine, very high blood pressure, kidney stones, or renal failure.

Nephrology is a subspecialty of internal medicine. To become a nephrologist, medical school is followed by additional training to become certified in internal medicine. An additional two or more years is spent specifically studying kidney disorders and their accompanying effects on the body.

## science practices CONNECTION for AP<sup>®</sup> Courses

### Think About It

What special adaptations do organs of the excretory system have for the excretion of wastes? Loop diuretics are drugs sometimes used to treat hypertension (high blood pressure). These drugs inhibit the reabsorption of  $\text{Na}^+$  and  $\text{Cl}^-$  ions by the ascending limb of the loop of Henle in the nephron. A side effect is that they increase urination. Why do you think this is the case?

## 32.3 | Excretion Systems

In this section, you will explore the following questions:

- How do vacuoles, present in microorganisms, work to excrete waste?
- How do flame cells and nephridia in worms perform excretory functions and maintain osmotic balance?
- How do insects use Malpighian tubules to excrete wastes and maintain osmotic balance?

## Connection for AP<sup>®</sup> Courses

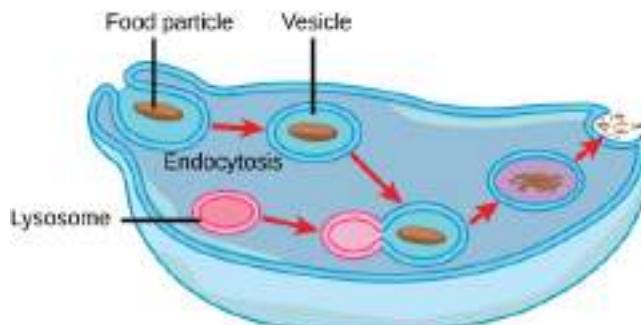

The information in this section is not within the scope for AP<sup>®</sup> other than to appreciate that other organisms, including microorganisms and invertebrate animals, use more primitive and simple mechanisms to get rid of metabolic waste and maintain osmotic balance. For example, contractile vacuoles are common in microorganisms; flame cells and nephridia in certain species and worms, and Malpighian tubules in insects are other examples of excretory systems. Osmoregulation is vital for all organisms to maintain homeostasis.

Information presented and examples highlighted in this section are not within the scope for AP<sup>®</sup> and do not align to the Curriculum Framework.

### Contractile Vacuoles in Microorganisms

The most fundamental feature of life is the presence of a cell. In other words, a cell is the simplest functional unit of a life. Bacteria are unicellular, prokaryotic organisms that have some of the least complex life processes in place; however, prokaryotes such as bacteria do not contain membrane-bound vacuoles. The cells of microorganisms like bacteria, protozoa, and fungi are bound by cell membranes and use them to interact with the environment. Some cells, including some leucocytes in humans, are able to engulf food by endocytosis—the formation of vesicles by involution of the cell membrane within the cells. The same vesicles are able to interact and exchange metabolites with the intracellular environment. In

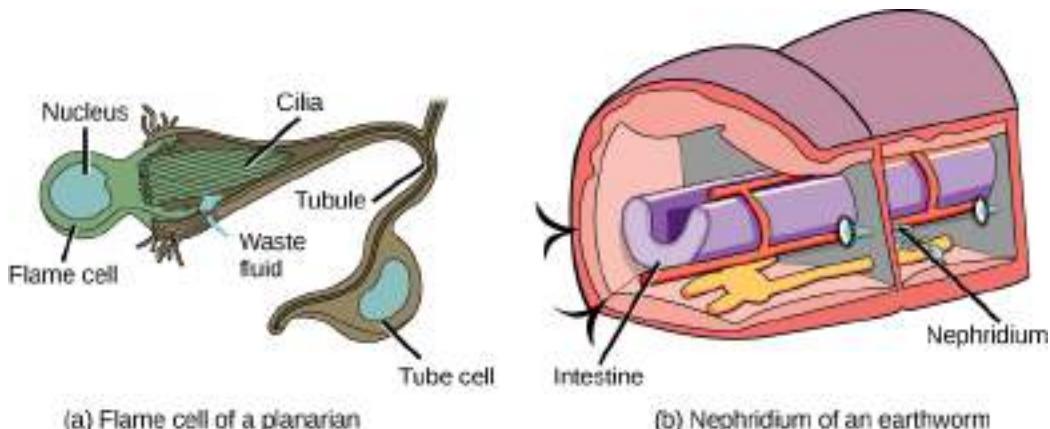

some unicellular eukaryotic organisms such as the amoeba, shown in **Figure 32.10**, cellular wastes and excess water are excreted by exocytosis, when the contractile vacuoles merge with the cell membrane and expel wastes into the environment. Contractile vacuoles (CV) should not be confused with vacuoles, which store food or water.

**Figure 32.10** Some unicellular organisms, such as the amoeba, ingest food by endocytosis. The food vesicle fuses with a lysosome, which digests the food. Waste is excreted by exocytosis.

## Flame Cells of Planaria and Nephridia of Worms

As multi-cellular systems evolved to have organ systems that divided the metabolic needs of the body, individual organs evolved to perform the excretory function. Planaria are flatworms that live in fresh water. Their excretory system consists of two tubules connected to a highly branched duct system. The cells in the tubules are called **flame cells** (or **protonephridia**) because they have a cluster of cilia that looks like a flickering flame when viewed under the microscope, as illustrated in **Figure 32.11a**. The cilia propel waste matter down the tubules and out of the body through excretory pores that open on the body surface; cilia also draw water from the interstitial fluid, allowing for filtration. Any valuable metabolites are recovered by reabsorption. Flame cells are found in flatworms, including parasitic tapeworms and free-living planaria. They also maintain the organism's osmotic balance.

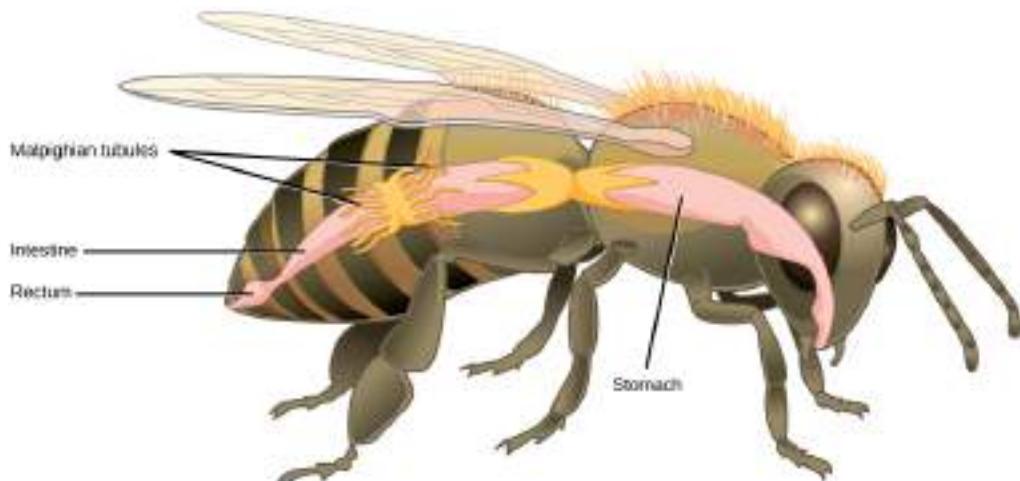

**Figure 32.11** In the excretory system of the (a) planaria, cilia of flame cells propel waste through a tubule formed by a tube cell. Tubules are connected into branched structures that lead to pores located all along the sides of the body. The filtrate is secreted through these pores. In (b) annelids such as earthworms, nephridia filter fluid from the coelom, or body cavity. Beating cilia at the opening of the nephridium draw water from the coelom into a tubule. As the filtrate passes down the tubules, nutrients and other solutes are reabsorbed by capillaries. Filtered fluid containing nitrogenous and other wastes is stored in a bladder and then secreted through a pore in the side of the body.

Earthworms (annelids) have slightly more evolved excretory structures called **nephridia**, illustrated in **Figure 32.11b**. A pair of nephridia is present on each segment of the earthworm. They are similar to flame cells in that they have a tubule with cilia. Excretion occurs through a pore called the **nephridiopore**. They are more evolved than the flame cells in that they have a system for tubular reabsorption by a capillary network before excretion.

## Malpighian Tubules of Insects

**Malpighian tubules** are found lining the gut of some species of arthropods, such as the bee illustrated in **Figure 32.12**. They are usually found in pairs and the number of tubules varies with the species of insect. Malpighian tubules are convoluted, which increases their surface area, and they are lined with **microvilli** for reabsorption and maintenance of osmotic balance. Malpighian tubules work cooperatively with specialized glands in the wall of the rectum. Body fluids are not filtered as

in the case of nephridia; urine is produced by tubular secretion mechanisms by the cells lining the Malpighian tubules that are bathed in hemolymph (a mixture of blood and interstitial fluid that is found in insects and other arthropods as well as most mollusks). Metabolic wastes like uric acid freely diffuse into the tubules. There are exchange pumps lining the tubules, which actively transport  $H^+$  ions into the cell and  $K^+$  or  $Na^+$  ions out; water passively follows to form urine. The secretion of ions alters the osmotic pressure which draws water, electrolytes, and nitrogenous waste (uric acid) into the tubules. Water and electrolytes are reabsorbed when these organisms are faced with low-water environments, and uric acid is excreted as a thick paste or powder. Not dissolving wastes in water helps these organisms to conserve water; this is especially important for life in dry environments.

**Figure 32.12** Malpighian tubules of insects and other terrestrial arthropods remove nitrogenous wastes and other solutes from the hemolymph.  $Na^+$  and/or  $K^+$  ions are actively transported into the lumen of the tubules. Water then enters the tubules via osmosis, forming urine. The urine passes through the intestine, and into the rectum. There, nutrients diffuse back into the hemolymph.  $Na^+$  and/or  $K^+$  ions are pumped into the hemolymph, and water follows. The concentrated waste is then excreted.

Visit [this site](http://openstaxcollege.org/l/malpighian) (<http://openstaxcollege.org/l/malpighian>) to see a dissected cockroach, including a close-up look at its Malpighian tubules.

What are Malpighian tubules and which organism possesses them?

- Malpighian tubules are the tubules within a nephron in humans.
- Malpighian tubules are the opening of the digestive sac in box jellyfish.
- Malpighian tubules are organs that filter waste from hemolymph in cockroaches.
- Malpighian tubules are tiny, bulb-shaped organs that open to an excretory pore in leeches.

## 32.4 | Nitrogenous Wastes

In this section, you will explore the following questions:

- What are the differences in the ways aquatic animals and terrestrial animals can eliminate toxic ammonia from their systems?
- What are the major byproducts of ammonia metabolism in mammals compared to fish, reptiles, birds, and insects?

### Connection for AP® Courses

Much information in this section is outside the scope for AP®. However, the concepts provide an opportunity to apply concepts explored in previous chapters, including chemistry. Of the four macromolecules in biological systems, both proteins and nucleic acids contain nitrogen. During the breakdown (catabolism) of nitrogen-containing macromolecules, carbon, hydrogen, and oxygen are extracted and stored in the form of carbohydrates and fats. However, excess nitrogen must be excreted from the body because nitrogenous wastes tend to form toxic **ammonia**, which raises the pH of body fluids and disrupts homeostasis. The formation of toxic ammonia requires energy in the form of ATP and large quantities of water to dilute it out of a biological system. Aquatic animals, such as fishes, can release ammonia directly into the environment. Animals that excrete ammonia are said to be **ammonotelic**. Terrestrial animals, including mammals, must detoxify ammonia by converting it into relatively nontoxic forms such as uric acid or urea. Animals that secrete urea as the primary nitrogenous waste material are called **ureotelic** animals. Birds and reptiles excrete uric acid, a water-insoluble form of nitrogenous waste, thus reducing water loss. From an evolutionary standpoint, life likely started in an aquatic environment, so it is not surprising that biochemical pathways like the conversion of ammonia to urea typical in mammals evolved to adapt to terrestrial conditions; more arid conditions probably led to the evolution of the uric acid pathway as a means of conserving water.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 2 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

## Nitrogenous Waste in Terrestrial Animals: The Urea Cycle

The **urea cycle** is the primary mechanism by which mammals convert ammonia to urea. Urea is made in the liver and excreted in urine. The overall chemical reaction by which ammonia is converted to urea is  $2 \text{ NH}_3 \text{ (ammonia)} + \text{CO}_2 + 3 \text{ ATP} + \text{H}_2\text{O} \rightarrow \text{H}_2\text{N-CO-NH}_2 \text{ (urea)} + 2 \text{ ADP} + 4 \text{ P}_i + \text{AMP}$ .

The urea cycle utilizes five intermediate steps, catalyzed by five different enzymes, to convert ammonia to urea, as shown in [Figure 32.13](#). The amino acid L-ornithine gets converted into different intermediates before being regenerated at the end of the urea cycle. Hence, the urea cycle is also referred to as the ornithine cycle. The enzyme ornithine transcarbamylase catalyzes a key step in the urea cycle and its deficiency can lead to accumulation of toxic levels of ammonia in the body. The first two reactions occur in the mitochondria and the last three reactions occur in the cytosol. Urea concentration in the blood, called **blood urea nitrogen** or BUN, is used as an indicator of kidney function.

**Figure 32.13** The urea cycle converts ammonia to urea.

## evolution CONNECTION

### Excretion of Nitrogenous Waste

The theory of evolution proposes that life started in an aquatic environment. It is not surprising to see that biochemical pathways like the urea cycle evolved to adapt to a changing environment when terrestrial life forms evolved. Arid conditions probably led to the evolution of the uric acid pathway as a means of conserving water.

Nitrogenous waste is eliminated in which forms?

- a. ammonia and  $\text{K}^+$  only
- b. uric acid and urea only
- c. urea, uric acid, and  $\text{K}^+$
- d. urea, uric acid, and ammonia

## Nitrogenous Waste in Birds and Reptiles: Uric Acid

Birds, reptiles, and most terrestrial arthropods convert toxic ammonia to **uric acid** or the closely related compound guanine (guano) instead of urea. Mammals also form some uric acid during breakdown of nucleic acids. Uric acid is a compound similar to purines found in nucleic acids. It is water insoluble and tends to form a white paste or powder; it is excreted by birds, insects, and reptiles. Conversion of ammonia to uric acid requires more energy and is much more complex than conversion of ammonia to urea **Figure 32.14**.

**Figure 32.14** Nitrogenous waste is excreted in different forms by different species. These include (a) ammonia, (b) urea, and (c) uric acid. (credit a: modification of work by Eric Engbretson, USFWS; credit b: modification of work by B. "Moose" Peterson, USFWS; credit c: modification of work by Dave Menke, USFWS)

## everyday CONNECTION

### Gout

Mammals use uric acid crystals as an **antioxidant** in their cells. However, too much uric acid tends to form kidney stones and may also cause a painful condition called gout, where uric acid crystals accumulate in the joints, as illustrated in **Figure 32.15**. Food choices that reduce the amount of nitrogenous bases in the diet help reduce the risk of gout. For example, tea, coffee, and chocolate have purine-like compounds, called xanthines, and should be avoided by people with gout and kidney stones.

**Figure 32.15** Gout causes the inflammation visible in this person's left big toe joint. (credit: "Gonzosoft"/Wikimedia Commons)

Why does gout often result in pain?

- The urethra swells, making urination slower and more painful.
- Uric acid crystals build up in the joints, resulting in painful body movements.
- Ammonia begins to degrade the linking of the bladder, causing constant pain.
- Urea is always highly concentrated, resulting in kidney stones that make urination painful.

### Think About It

In terms of evolution, why is the urea cycle advantageous in terrestrial organisms? Why is it reasonable to conclude that the uric acid cycle of reptiles was an adaptation to arid environments?

## 32.5 | Hormonal Control of Osmoregulatory Functions

In this section, you will explore the following questions:

- How do hormonal cues help the kidneys synchronize the osmotic needs of the body?
- How do hormones and other chemical messengers including epinephrine, norepinephrine, rennin-angiotensin, aldosterone, antidiuretic hormone, and atrial natriuretic peptide help regulate waste elimination, maintain correct osmolarity, and perform other osmoregulatory functions?

### Connection for AP® Courses

As we learned in an earlier section, the excretory system works with the circulatory and endocrine systems to maintain osmotic balance, eliminate wastes, and maintain blood pressure. For AP®, you do not need to memorize the list of hormones that control osmoregulatory functions or their specific function(s). However, information in this section applies to concepts previously explored.

The kidneys synchronize with hormonal cues. As you recall from our study of the endocrine system, hormones are small messenger molecules that travel in the bloodstream to affect a target cell. Different regions of the nephron have specialized cells with receptors to respond to chemical messengers and hormones. **Table 32.1** summarizes the hormones that control the osmoregulatory functions. For example, the fight/flight hormones epinephrine and norepinephrine, released by the adrenal medulla and nervous subsystem, respectively, halt kidney function temporarily when the body is under extreme stress and much of the body's energy is used to combat imminent danger. Another example is the rennin-angiotensin-aldosterone system that increases blood pressure and volume primarily by constricting blood vessels. Another hormone, antidiuretic hormone (ADH) increases membrane permeability to water in the collecting ducts of the nephron by adding aquaporins, causing more water to be reabsorbed. You've experienced the effects of ADH when it's hot outside and you're running around the athletic field; since you're losing water by sweating and breathing hard, ADH prevents you from losing more water in urine and risking dehydration.

Information presented and the examples highlighted in the section support concepts outlined in Big Idea 3 of the AP® Biology Curriculum Framework. The AP® Learning Objectives listed in the Curriculum Framework provide a transparent foundation for the AP® Biology course, an inquiry-based laboratory experience, instructional activities, and AP® exam questions. A learning objective merges required content with one or more of the seven science practices.

|                                   |                                                                                                                                   |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Big Idea 3</b>                 | Living systems store, retrieve, transmit and respond to information essential to life processes.                                  |
| <b>Enduring Understanding 3.D</b> | Cells communicate by generating, transmitting and receiving chemical signals.                                                     |
| <b>Essential Knowledge</b>        | <b>3.D.2</b> Cells communicate with each other through direct contact with other cells or from a distance via chemical signaling. |
| <b>Science Practice</b>           | <b>6.2</b> The student can construct explanations of phenomena based on evidence produced through scientific practices.           |

|                            |                                                                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Learning Objective</b>  | <b>3.34</b> The student is able to construct explanations of cell communication through cell-to-cell direct contact or through chemical signaling.                             |
| <b>Essential Knowledge</b> | <b>3.D.2</b> Cells communicate with each other through direct contact with other cells or from a distance via chemical signaling.                                              |
| <b>Science Practice</b>    | <b>1.1</b> The student can create representations and models of natural or man-made phenomena and systems in the domain.                                                       |
| <b>Learning Objective</b>  | <b>3.35</b> The student is able to create representation(s) that depict how cell-to-cell communication occurs by direct contact or from a distance through chemical signaling. |

### Hormones That Affect Osmoregulation

| Hormone                             | Where produced                                   | Function                                                                                                                                |
|-------------------------------------|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Epinephrine and Norepinephrine      | Adrenal medulla                                  | Can decrease kidney function temporarily by vasoconstriction                                                                            |
| Renin                               | Kidney nephrons                                  | Increases blood pressure by acting on angiotensinogen                                                                                   |
| Angiotensin                         | Liver                                            | Angiotensin II affects multiple processes and increases blood pressure                                                                  |
| Aldosterone                         | Adrenal cortex                                   | Prevents loss of sodium and water                                                                                                       |
| Anti-diuretic hormone (vasopressin) | Hypothalamus (stored in the posterior pituitary) | Prevents water loss                                                                                                                     |
| Atrial natriuretic peptide          | Heart atrium                                     | Decreases blood pressure by acting as a vasodilator and increasing glomerular filtration rate; decreases sodium reabsorption in kidneys |
